No products have been created based on developed by the Infrared Data Association (IrDA), not 802.11. Even if products were created around the IR PHY, the big drivers to adopt 802.11 are flexibly penetrating solid objects. Using infrared light instead of radio waves seems to have several advantages. IR ports are less expensive than radio transceivers—in fact, the cost waves operate at a totally different frequency. This leads to a second advantage: Security concerns regarding 802.11 are largely based on the threat of conference room or office by simply closing the door. IR-based LANs can offer some of the advantages of flexibility and mobility but with less security the IR PHY. The infrared ports on laptops comply with a set of standards and mobility, which are better achieved by radio's longer range.

IrDA

IrDA (Infrared Data Association) is an industry-sponsored organization set up in 1993 to create international standards for the hardware and software used in infrared communication links (Williams, 2000; Vitsas & Boucouvalas, 2003). In this special form of radio transmission, a focused ray of light in the infrared frequency spectrum, measured in terahertz, or trillions of hertz (cycles per second), is modulated with information and sent from a transmitter to a receiver over a relatively short distance. Infrared radiation (IR) is the same technology used to control a TV set with a remote control.

IrDA has a set of protocols covering all layers of data transfer and, in addition, has some network management and interoperability designs. IrDA protocols have IrDA DATA as the vehicle for data delivery and IrDA CONTROL for sending the control information. In general, IrDA is used to provide wireless connectivity technologies for devices that would normally use cables for

connectivity (Robertson, Hansen, Sorensen, & Knutson, 2001).

IrDA is a point-to-point, narrow angle, ad-hoc data transmission standard designed to operate over a distance of 0 to 1 meter and at speeds of 9600 bps to 16 Mbps. Adapters now include the traditional upgrades to serial and parallel ports. In the IrDA-1.1 standard, the maximum data size that may be transmitted is 2048 bytes and the maximum transmission rate is 4 Mbps (Vitsas & Boucouvalas, 2002).

HomeRF

HomeRF (HomeRF) is a subset of the International Telecommunication Union (ITU) and primarily works on the development of a standard for inexpensive RF voice and data communication. The HomeRF Working Group has also developed the Shared Wireless Access Protocol (SWAP). SWAP is an industry specification that permits PCs, peripherals, cordless telephones and other devices to communicate voice and data without the usage of cables. It uses a dual protocol stack: DECT for voice, and 802.11 packets for data. It is robust, reliable, and minimizes the impact of radio interference. Its target applications are home networking, as well as remote control and automation.

Bluetooth

Bluetooth (Chiasserini, Marsan, Baralis, & Garza, 2003) is a high-speed, low-power microwave wireless link technology, designed to connect phones, laptops, PDAs and other portable equipment together with little or no work by the user. Unlike infrared, Bluetooth does not require line-of-sight positioning of connected units. The technology uses modifications of existing wireless LAN techniques but is most notable for its small size and low cost. Whenever any Bluetooth-enabled devices come within range of each other, they instantly transfer address information and establish small networks between each other, without the user being involved. To a large extent, Bluetooth have motivated the present WPAN attempts and conceptualizations; moreover, it constitutes the substance of the IEEE 802.15.1 WPAN standard. For reader reference, we are attaching general specifications in Table 2 for Bluetooth.

Bluetooth and 3G

Third-generation (3G) mobile telephony networks are also a familiar source of hype. They promise data rates of megabits per cell, as well as the "always on" connections that have proven to be quite valuable to DSL and cable modem customers. In spite of the hype and press from 3G equipment vendors, the rollout of commercial 3G services has been continually pushed back.

At the same time as 3G standards are being introduced, other air interfaces have been developed and standardized. First of all, Bluetooth is already available, enabling devices to communicate over short distances. The strength of Bluetooth is low power consumption and a design enabling low-cost implementations. Bluetooth was integrated into mobile phones, laptop computers, PDAs, and so forth. The first version of Bluetooth offers up to 700 kbps, but higher data rates, up to approxi-

Table 2. Bluetooth specifications

Frequency range	Modulation	Multiple access	Duplex	Channel bandwidth	Number of channels	Peak data rate
2402 MHz to 2480 MHz	GFSK	FHSS	TDD	1 MHz	79	723,2 kbit/s

mately 10 Mbps, are currently being standardized for later releases.

In contrast to Bluetooth and 3G, equipment based on the IEEE 802.11 standard has been an astounding success. While Bluetooth and 3G may be successful in the future, 802.11 is a success now. Apple initiated the pricing moves that caused the market for 802.11 equipment to explode in 1999. Price erosion made the equipment affordable and started the growth that continues today. IEEE

802.15 WPAN

802.15 is a communications specification that was approved in early 2002 by the Institute of Electrical and Electronics Engineers Standards Association (IEEE-SA) for wireless personal area networks (WPANs) (Chiasserini et al., 2003). The initial version, 802.15.1, was adapted from the Bluetooth specification and is fully compatible with Bluetooth 1.1.

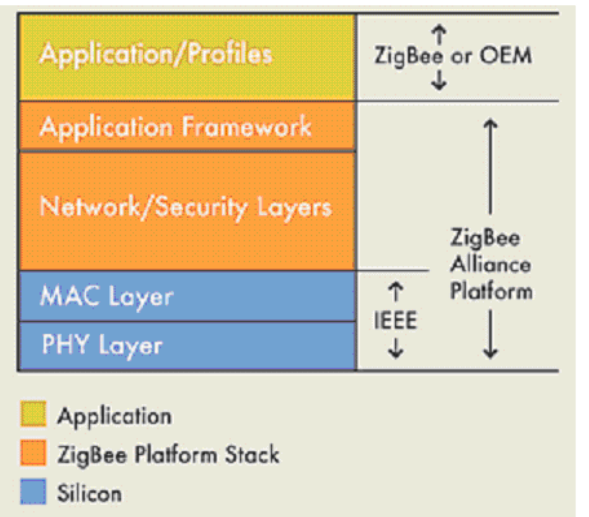
The IEEE 802.15 Working Group proposes two general categories of 802.15, called TG4 (low rate) and TG3 (high rate). The TG4 version provides data speeds of 20 Kbps or 250 Kbps. The TG3 version supports data speeds ranging from 11 Mbps to 55 Mbps. Additional features include the use of up to 254 network devices, dynamic device addressing, support for devices in which latency is critical, full handshaking, security provisions, and power management. There will be 16 channels in the 2.4-GHz band, 10 channels in the 915-MHz band, and one channel in the 868-MHz band (HomeRF; Shiraishi, 1999).

The IEEE plans to refine the 802.15 specification to work with the specification and description language (SDL), particularly SDL-88, SDL-92, and SDL-2000 updates of the International Telecommunication Union (ITU) recommendation Z.100.

ZigBee

Wireless networks present colossal opportunities; at the same time, they are constrained by substantial development challenges. ZigBee™ provides standard-based solution for lightweight wireless networks based on the IEEE 802.15.4 (You, Park, Ju, Kwon, & Cho, 2001). Figure 2 provides clear elaboration for the ZigBee stack

Figure 2. ZigBee standard stack definition



definition. While IEEE has defined the standards for MAC and PHY layers, the ZigBee™Alliance has added standards for network, security, and application layers.

Our readers may also refer to the general description Table 3 of ZigBee.

To conclude our section, a comparison in Table 4 among a set of frequently used personal wireless not working up to the standard is provided. This table states the standard bandwidth, power consumption, protocol stack size, stronghold, and finally draws preferred applications for each standard.

APPLICATIONS AND SERVICES

Overview

The concept of mobile multimedia services was first introduced in 1992 when the ITU realized that mobile communications were playing an increasingly important role. It began working on a project called *FPLMTS* (Future Public Land Mobile Telecommunications System) aiming to unite the world under a single standard.Given the fact, however, that this acronym is difficult to pronounce, it was subsequently renamed *International Mobile Telecommunications – 2000* (IMT-2000).

Table 3. ZigBee (IEEE 802.15.4) specifications

Frequency range	Modulation	Multiple access	Duplex	Channel bandwidth	Number of channels	Peak data rate
2.4 GHz to 2.4835 GHz (World) 902 MHz to 928 MHz (America) 868.3 MHz (Europe)	BPSK (868/915 MHz), OQPSK (2.4 GHz)	CSMA/ CA	TDD	5 MHz	1 (868 MHz) 10 (915 MHz) 16 (2.4 GHz)	20 kbit/s (868 MHz) 40 kbit/s (915 MHz) 250 kbit/s (2.4 GHz)

Table 4. Wireless technology comparison table

Standard	Bandwidth	Power Consumption	Protocol Stack Size	Stronghold	Applications
Wi-Fi	Up to 54Mbps	400+mA TX, standby 20mA	100+KB	High data rate	Internet browsing, PC networking, file transfers
Bluetooth	1Mbps	40mA TX, standby 0.2mA	~100+KB	Interoperability, cable replacement	Wireless USB, handset, headset
ZigBee	250kbps	30mA TX, standby 1uA	4”32KB	Long battery life, low cost	Remote control, battery-operated products, sensors

IMT-2000 is a single family of compatible standards defined by a set of ITU-R Recommendations. The main objectives for IMT-2000 are (UMTS Forum Report, 2000):

- High data rates, 144 Kbps/384 Kbps for high mobility users with full coverage and 2 Mbps for low mobility users with limited coverage,
- Capability for multimedia application and all mobile applications,
- High spectrum efficiency compared to existing systems,
- High flexibility to introduce new services,
- High degree of commonality of design worldwide, and
- Use of a small pocket terminal with seamless global roaming.

The main applications will not be on only traditional voice communications, but also on services such as e-mail, short messages, multimedia, simultaneous voice and data and the broadband integrated service digital network (B-ISDN) access (UMTS Forum Report, 2000). Although the PC has been the dominant Internet client, soon mobile phones and personal digital assistants (PDAs) will outnumber PCs and be the major source of Internet connections. With the third-generation (3G) network, mobile device users won't have to worry about bandwidth. People will access video on their phones as easily as they do on their PCs. In fact, the development of GSM Networks and terminals to support more advanced data bearer technologies has allowed the introduction of new exciting data services. These technologies allow a greater bandwidth and more capable execution environment permitting the development of mobile applications. The world has become increasingly computer centric, and computer applications are now used for a number of tasks such as communications, financial management, information retrieval, entertainment, and game playing.

It is a natural progression for the user to expect these applications to be available for them on their mobile terminal. The initial developments in mobile applications were basic, running on the GSM SIM Card using SIM toolkit interfacing through capable terminals and using SMS to communicate with the application infrastructure. These were followed by the introduction of browsers utilizing special mobile protocols (WAP, HDML, etc.) and the basic data capabilities of the GSM terminals of the time. These allow the user to use their mobile terminal to access basic text format content such as news, sport, entertainment, and information, among others.

The introduction of high bandwidth capability allows for richer applications, and the packet switched nature of GPRS networks allows for more efficient applications. They will smooth the progress of the introduction of true multimedia services such as multimedia messaging service (MMS) which will allow the user to send and receive messaging containing pictures, images, sound, and text. New network features, such as location servers, can allow the mobile applications to be improved to tailor the way they work, and improve the value to the user. Mobile commerce is the effective delivery of electronic commerce into the consumer's hand, anywhere, using wireless technology. This advance has the power to transform the mobile phone into a "mobile wallet." Already, major companies have begun to establish partnerships with banks, ticket agencies, and top brands to take benefit of the retail outlet in the consumer's hand.

Location based services provide personalized services to the subscriber based on their current position. Two categories of methods can be used to find the location of the subscriber: basic and advanced. Basic positioning methods are based on the information of the cell the subscriber is using (cell ID). This can be used alone, or together with other information available in the network such as timing advance and network measurement reports. This information is available for

all handsets. Advanced techniques will be available in new handsets such as enhanced observed time difference and assisted GPS which uses the GSM network to help the reception of the freely available GPS system. The division of position technologies above is based on accuracy of the positioning method. Other factors also very important are for example complexity of the system, availability of the positioning technology in the network (e.g., assisted-GPS may not be available everywhere) and the investment needed on the network side and in handsets. Mobile video streaming is another application of whole big set of applications in field of mobile multimedia. The facts of high bit rate and smart phone availability will put a hundred of applications ongoing for mobile multimedia.

Last but not least, interesting new technology, the so-called mobile TV, has strongly emerged in the mobile multimedia field as taking breath and killer application. Interest in television services over cellular or broadband wireless networks is intensifying as operators seek a new and high margin application. Philips Semiconductors is predicting that, within a decade, the majority of its television chips will go into cell phones, not conventional television sets.

Classification of Services

Mobile multimedia services aim to combine the Internet, telephones, and broadcast media into a single device (UMTS Forum Report, 2000). To achieve this, IMT-2000 systems have been designed with six broad classes of service in mind. None of them are yet set in hardware but they are useful for regulators planning coverage and capacity, and perhaps for people buying terminals when they finally become available.

It's likely that 3G devices will be rated according to the types of service they can access, from a simple phone to a powerful computer. Three of the service classes are already present to some extent on 2G networks, while three more are new and involve mobile multimedia. In order of increasing data rate:

- **Voice:** Even in the age of high-speed data, this is still regarded as the "killer app" for the mobile market. 3G will offer call quality at least as good as the fixed telephone network, possibly with higher quality available at extra cost. Voicemail will also be standard and eventually integrated fully with email through computerized voice recognition and synthesis.
- **Messaging:** This is an extension of paging, combined with Internet e-mail. Unlike the text-only messaging services built into some 2G systems, 3G will allow email attachments. It can also be used for payment and electronic ticketing.
- **Switched data:** This includes faxing and dial-up access to corporate networks or the Internet. With always-on connections available, dial-up access ought to be obsolete, so this is mainly included to support legacy equipment. In 3G terms, legacy means any product that doesn't support a fully packet-switched network.
- **Medium multimedia:** This is likely to be the most popular 3G service. Its downstream data rate is ideal for Web surfing. Other applications include collaborative working, games, and location-based maps.
- **High multimedia:** This can be used for very high-speed Internet access, as well as for high-definition video and CD-quality audio on demand. Another possible application is online shopping for "intangible" products that can be delivered over the air; for example, music or a program for a mobile computer.
- **Interactive high multimedia:** This can be used for fairly high-quality videoconferencing or videophones, and for telepresence, a combination of videoconference and collaborative working.

The data rates of these services are shown in Table 1, together with their level of asymmetry and switching mode. These services refer to three basic levels by which these services are structured according to the dependencies among these services:

1. **Basic level services:** Those services form the building blocks of other more complex applications and services, such as voice messaging, data retrieval, video, and so forth, and can be used as stand-alone services or form the ingredients of higher level services and applications.
2. **Value added services:** Those services form the intermediate level services formed by one or more basic level services. VAS offer optimized functionality to suit the needs of diverse professional groups. Examples of such services are wireless home networking, high data rate PAN, high density networks, P2P communication collaboration, Internet/ Intranet access, video conferencing, telemetry, location based services, payments, and UMS.
3. **High level applications:** Those address the specific requirements and interests of professional or consumer user groups. These are functionally stand-alone and serve the full range of user needs supporting services forms them. Examples can be business applications, transaction management, information applications, entertainment applications, telematics, construction, electronic healthcare, provision, e-government, e-learning, wireless home networking, and so on.

The above taxonomy refers to the functionality of the service and the group of users it targets. In the context of mobile multimedia, the basic level services refer to the collection, sharing and exchange of multimedia data, while the value added level refers to the provision and distribution of the multimedia information and the high level applications is concerned about the usage and consumption of the data.

THE FUTURE OF MOBILE MULTIMEDIA

Future generation mobile terminals will start to incorporate ubiquitous network functionality by efficiently dealing with a massive amount of communication modes and various multimedia applications. Further, these terminals will also need adaptive behavior to intelligently manage the computational resources that will be distributed and shared across the environing systems. Researchers should find integrated research platform aiming to resolve the fundamental technological issues for future mobile terminals allowing the true ubiquitous network environment to become a reality. Complexity, cost, power consumption, high throughput at low latency, and flexibility are the five primary hurdles in developing a mobile terminal.

In addition, many types of objects as well as people will have network functions and communicate with each other through networks. Therefore, different communication relationships such as person to person, machine to machine and mainly machine to person and vice versa, will determine mobile and wireless communications in the future.

Given the increasing demand for flexibility and individuality in society, the mean for the end-user might be assessed. Potentially, the value would be in the diversity of mobile applications, hidden from the complexity of the underlying communications schemes. This complexity would be absorbed into an intelligent personality management mechanism, which would learn and understand the needs of the user, and control the behavior of their reconfigurable and open wireless terminals accordingly in terms of application behavior and access to future support services.

In the future wireless service provision will be characterized by global mobile access (terminal and personal mobility), high quality of services (full coverage, intelligible, no drop and no/lower call blocking and latency), and easy and simple access to multimedia services for voice, data, messages, video, WWW, GPS, and so forth, via one user terminal.

End-to-end secured services will be fully coordinated via access control, authentic use of biometric sensors and/or smart card and mutual authentication, data integrity, and encryption. User added encryption feature for higher level of security will be part of the system.

Considering how second-generation systems have evolved by adding more and more system capabilities and enhancements to make them resemble the capabilities of 3G systems; it is possible that with third-generation systems there may be a continuum of enhancements that will render those systems practically indistinguishable from future generation systems. Indeed, it is expected that it will be more difficult to identify distinct generation gaps, and such a distinction may only be possible by looking back at some point in the future.

Progress has also been made in the development of other signal processing techniques and concepts for use in tomorrow's wireless systems. These include smart antennas and diversity techniques, better receivers, and hand over and power control algorithms with higher performance (Bi, Zysman, & Menkes, 2001).

ACKNOWLEDGMENTS

The authors of this chapter would like to express their heartfelt thanks to Huang Hsin-Yi and Lin Yu-Hua (Monica) for their proofreading our chapter.

INTRODUCTION

In the past few years, industry has introduced cellular phones with increasing processing capabilities and powerful wireless communication technologies. These wireless technologies provide the user with mechanisms to easily access services, enabling file sharing among devices with the same technology interfaces (Mallick, 2003). In the context of electronic commerce, which demands new techniques and technologies to attract consumers, these wireless technologies aim to simplify the shopping process and provide up-to-date information about available products.

In order to exemplify the application of mobile and wireless technologies to satisfy these new commerce functionalities and needs, we present in this article the interactive multimedia system (IMS). IMS is a system for sharing multimedia files between servers running on PCs, and client applications running on mobile devices. The system was conceived initially to be deployed in CDs/DVDs and rental stores to make available product information in a simple and interactive way.

In a general way, the system allows a user to obtain information about available products through a mobile device. Then, a user can listen or watch parts (stretches) of available videos or songs. For that, the user needs to enter the store, choose a product in the store shelf, and type its identity code in the mobile device, choosing which

music (or video) to listen to (or watch).

The IMS system has a client/server architecture, where the server was developed in C++ for the Windows operating system and the client application was developed in C++ for the Symbian operating system, which is a mobile device operating system mainly used in smart phones. Client/server communication is performed based on Bluetooth wireless technology. Bluetooth is suitable for this kind of application because it has a satisfactory transmission rate with enough range, and it is also supported by more than 500 million mobile devices (Bluetooth Official Website, 2006).

The rest of this article is organized as follows. In next section we present a background of the main technologies used in this project. We then present the architecture of the proposed system and describe how the system works, before discussing future trends of mobile multimedia systems and offering final remarks.

BACKGROUND

This section provides an overview of the main technologies used in the IMS development. More specifically, we outline the Bluetooth wireless technology and the programming language used with the Symbian Operational System.

Bluetooth

To provide communication between devices, the IMS client/server architecture uses the Bluetooth wireless technology. Bluetooth is a short-range wireless technology present in a large number of smart phones of the Symbian OS Series 60 platform. It is suitable for fast file exchange, including text files, photo files, and short video files. Bluetooth technology covers a distance of about 10 meters for class 2 devices (most common devices), and each server (or master) can be connected to up to seven slaves in its coverage area (Mallick, 2003). Another important feature of Bluetooth is its lower power consumption, around 2.5 mW at most, which reinforces its use in embedded devices.

With Bluetooth, it is possible to use two kinds of connections: ACL (asynchronous connectionless) and SCO (synchronous connection oriented) (Andersson, 2001). ACL links are defined for data transmission, supporting symmetrical and asymmetrical packet-switched connections. In this mode, the maximum data rate could be 723 kbps in one direction and 57.6 kbps in the other direction, and these rates are controlled by the master of a cell. SCO links support only a symmetrical, circuit-switched, point-to-point connection for primarily voice traffic. The data rate for SCO links is limited to 64 kbps, and the number of devices connected at the same time with the master is restricted to three devices.

In the Bluetooth protocol stack, some profiles that implement some kind of particular communication partner are defined. The general profiles in Bluetooth stack are: GAP (generic access profile), SDAP (service discovery application profile), SPP (serial port profile), and GOEXP (generic object exchange profile) (Forum Nokia, 2003). GAP defines generic procedures related to discovery of Bluetooth devices and links management aspects of connecting Bluetooth devices. SDAP defines features and procedures to allow an application in a Bluetooth device to discover services of another Bluetooth device. With SPP used in ACL links, it is possible to emulate serial cable connections using RFCOMM (RS232 Serial Cable Emulation Profile) between two peer devices. RFCOMM emulates RS-232 (Serial Cable Interface Specification) signals and can thus be used in applications that are formerly implemented with a serial cable. The GOEXP profile defines protocols and procedures that should be used by applications requiring object exchange capabilities.

Symbian

Symbian is an operating system specifically designed for mobile devices with limited resources, such as memory and processor performance. The programming language C++ for Symbian provides a specific API (application program interface), with new features for the programmer that allow access to services such as telephony and messaging (Stichbury, 2004). Also, the Symbian C++ API enables programmers to efficient deal with multitasking and memory functions. These functions reduce memory-intensive operations. Symbian OS is event driven rather than multi-thread. Although multi-thread operations are possible, they potentially create kilobytes of overhead per thread. Services in Symbian OS are provided by servers through client/server architectures. For developing applications, Symbian offers an application framework, which constitutes a set of core classes that are the basis and structure of all applications.

The Symbian OS architecture can be described by a layered approach, as illustrated in Figure 1.

The layers can be defined as follows:

- **User Interface (UI):** Can be specifically defined per vendor or per family of mobile devices, such as Series 60 platform devices;
- **Application Module:** Allows access to applications' built-in functionality concerned with data processing and not how it is presented for the user;
- **System Module:** Contains the set of OS APIs; and
- **Kernel:** The core of the operational system and cannot be directly accessed by user programs.

The mobile application was implemented using a Series 60 platform (Series 60 Website, 2006; Edwards & Barker, 2004). Series 60 is a complete smart phone-based UI design reference. It completes the Symbian OS architecture with a configurable graphical user interface library and a suite of applications, besides other general-purpose engines.

SYSTEM ARCHITECTURE

This section presents the IMS architecture. As introduced earlier, the IMS system has a client/server architecture, where the server was developed in C++ for the Microsoft Windows OS and the client application was developed in C++ for Symbian OS. Client/server communication is performed based on Bluetooth wireless technology, which can provide connection to up to seven users at the same time. Figure 2 illustrates a general system view.

According to this general view, the system can be divided into three specific modules: mo-

Figure 1. Symbian OS architecture

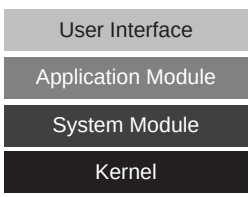

Figure 2. IMS general view

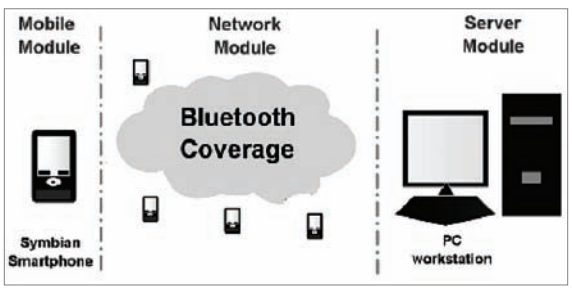

bile, network, and server. The mobile module is composed of the software running on mobile devices, such as smart phones. It offers a friendly and intuitive user interface, which is responsible for showing relevant information about available products. This information is obtained by typing the product code into the device. Then, the product description is returned with an option to run the multimedia file related to the product. Also, the mobile module controls a multimedia player installed together with the IMS software. Screenshots of the IMS mobile application are presented in Figure 3.

The network module controls the mobile network, in this case the Bluetooth wireless technology. To handle the connection, the network module offers an application layer protocol to manage the exchange of messages between the other two modules. This protocol is text based. Also, this module is responsible to control the transfer of files using the Bluetooth Serial Port Profile (SPP). The SPP profile is supported by Symbian (and Series 60 Platform) Bluetooth-enabled devices (Jipping, 2003). The system can support more than seven users by sharing the available Bluetooth communication ports at server side. This way, after using one communication port with one user, the network module switches the port to another user if necessary.

Finally, the server module is responsible for database and system management. Files and relevant information (description of video or song, time, author, etc.) are stored into a database. When required, the server sends relevant information about a specific product. After confirmation from the mobile software, the server sends the multimedia file.

SYSTEM EXECUTION

In this section we describe how IMS works. For this execution scenario, consider that the client has entered the IMS Bluetooth coverage area. Then, he/she has chosen a product to retrieve information (such as a DVD or CD) available at the store shelf. After that, as illustrated in Figure 4, the following steps are performed:

1. The user types the product identification code into the mobile device software. Then, the software running on the mobile device searches for the IMS server using Bluetooth technology. After finding the IMS server, the IMS network module establishes the connection between the mobile device and the server. Using a specific application protocol, the IMS software asks for information about that

Figure 3. IMS screenshots

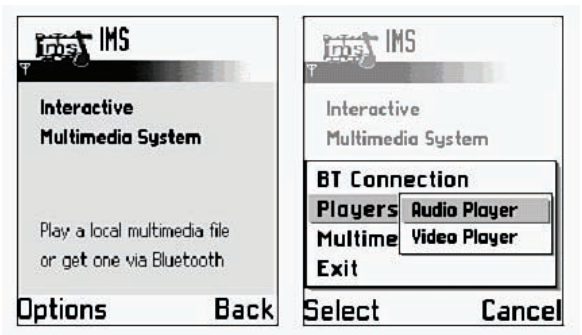

Figure 4. IMS operation

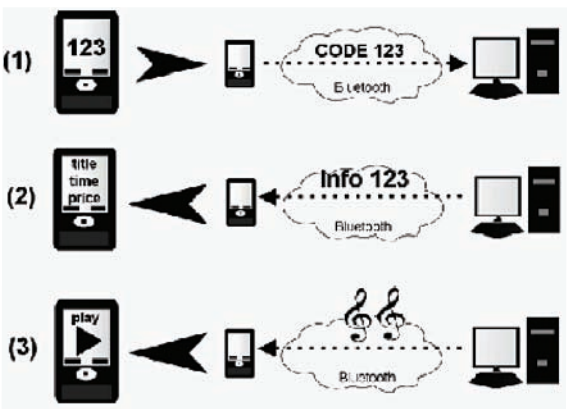

product code, such as audio/video stretches, release notes, and so forth.
2. If the information is available, the server module retrieves it from the database and returns it to the mobile device through the Bluetooth link. Then, the IMS software receives that information and displays it to the client, who will have available the description and the option to run a multimedia file.
3. When the client chooses to run the file, it is downloaded through the Bluetooth link and executed using a multimedia player managed by the IMS software.

FUTURE TRENDS

Today, the mobile multimedia area tends to investigate and develop mechanisms for carrying multimedia streams over wireless links, as described by Chen, Kapoor, Lee, Sanadidi, and Gerla (2004). Mobile multimedia systems are focused on providing multimedia streams directly to the mobile device in an efficient way. Future interactive multimedia systems will offer real-time multimedia streams, with more general services such as IPTV (television over IP) (Santos, Souto, Almeida, and Perkusich, 2006), radio, and so forth. Also, with the advent of smart phones with different wireless interfaces such as Wi-Fi and Bluetooth, those systems will support heterogeneous technologies offering different kinds of services for different kinds of devices.

Another prominent future trend is related to pervasive computing (Weiser, 1991; Saha & Mukherjee, 2003; Satyanarayanan, 2001). Within this context, users with mobile and wireless technology access can define their personal preferences to adapt systems and environments according to it. IMS, in the future, could be used in a pervasive infrastructure enabling file sharing according to personal preferences of users. IMS can be primarily used to delivery file in the pervasive environment, and in the future can be associated with variable bit rate multimedia streaming according to battery life of a mobile device or any kind of strategy based on the user's profile.

CONCLUSION

Mobile multimedia systems are becoming reality, and more and more accessible to ordinary users. These users, as potential consumers, are attracting industry and commerce attention, motivating research and development of several solutions in this area. Within this context, one of the relevant efforts is to promote multimedia file sharing.

To illustrate the large application of multimedia file sharing to support consumer activities, we presented in this article an interactive multimedia system. IMS provides attractive and interactive ways for users to obtain product information, which can be used in several commerce domains.

Interactive multimedia systems, such as IMS, are very useful and have great relevance for multimedia commerce. They could substitute traditional multimedia players installed in stores, offering a new way of interacting with clients using mobile devices.

INTRODUCTION

Users of the Internet have become increasingly more mobile. At the same time, mobile users want to access Internet wireless services demanding the same quality as over a wire. Emerging new protocols and standards, and the availability of WLANs, cellular data and satellite systems are making the convergence of wired and wireless Internet possible. Lack of standards is however still the biggest obstacle to further development. Mobile devices are generally more resource constrained due to size, power, and memory. The portability making these devices attractive greatly increases the risk of exposing data or allowing network penetration.

Multimedia applications in mobile devices require support for continuous-media data types, high network and memory bandwidth, low power consumption, low weight and small size, and QoS (quality of service). Also security features like authentication and authorization for multimedia content as well as secure connectivity to multimedia sources with possibilities to verify the integrity and guarantee the confidentiality of delivered multimedia content are required (Havinga, 2000). A mobile user must also be able to roam between different networks, also between different types of networks (WLAN, cellular, etc.), and still maintain an ongoing secure multimedia application session.

A standard for a mobile multimedia system architecture has also been proposed (MITA, 2002). Two technologies, MBMS (Multimedia Broadcast/Multimedia Service [see MBMS, 2004]), and DVB-H (digital video broadcasting handheld [see ETSI EN 302 304, 2004]), are being developed for delivery of multimedia content to mobile devices.

To fulfill all security requirements for multimedia applications in a mobile environment, while still maintaining QoS, is a challenging issue. In this chapter, the security requirements and proposed solutions for fulfilling these requirements are discussed. Attention is paid to ongoing related research. However, in order to achieve a secure mobile multimedia environment, also basic mobile device security issues must be seriously taken into account.

BACKGROUND

A mobile computer is a computing device intended to maintain its functionality while moving from one location to another. Different types of mobile computers are:

- Laptops
- Sub-notebooks
- PDAs (personal digital assistants)
- Smartphones

These devices can be divided in two groups: handheld devices and portable PCs. Handheld devices, such as PDAs and smartphones, are pocket-sized computing devices with smaller computing, memory, and display capacity compared to basic desktop computers. Portable PCs such as laptops and sub-notebooks, however, don't significantly differ from the desktops on this area.

Mobile computing and mobility are generic terms for describing the ability to use mobile devices for connecting to and using centrally located applications and/or services over a wireless network. Mobile multimedia can be defined as a set of protocols and standards for exchanging multimedia information over wireless networks. Mobile multimedia user services are usually divided in three categories (MBMS, 2004):

- streaming services like real-time video and audio streams, TV and radio programs, and on-demand video services;
- file download services; and
- carousel services, for example, news delivery with timed updating of text, image, and video objects.

For setup of sessions using multimedia streaming services in IP-based networks is used a signaling protocol, the Session Initiation Protocol (SIP), which is an Internet standard adopted by the Internet Engineering Task Force (IETF). SIP is a text-based client server protocol, in which servers respond to SIP requests sent by clients. SIP entity types are user agents (SIP clients), proxy servers, redirect servers, and registrar servers. Two or more participants can establish a session consisting of multiple media streams. SIP also provides application level mobility, which includes personal, terminal, session, and service mobility. *Personal mobility* means that a user ID provides global accessibility. *Terminal mobility* means that a mobile end-user device can maintain streaming media sessions while moving within and between IP subnets. *Session mobility* means users can change terminals during streaming media sessions and still maintain their sessions. *Service mobility* means that users maintain their streaming media session while moving, changing terminal devices, and changing network service providers (Rosenberg et al., 2002).

SIP does not define any protocol for media transport. However, streaming services typically use the Real-time Transport Protocol (RTP) over UDP. RTP defines a standardized packet format for delivering audio and video over the Internet (Schulzrinne, Casner, Frederick, & Jacobson, 2003).

Multimedia applications for handheld devices require support for continuous-media data types, high network and memory bandwidth, low power consumption, low processing power, low memory capacity, low weight and small size, and quality of service. Therefore, for multimedia applications, most of the research has currently been focused on smoothness of the multimedia data delivery and processing. Most application developers have chosen not to take the security issues into account. Security should be a natural part of the application development process. However, implementation of security in handheld device applications is complex and furthermore often tends to distract application developers from developing needed multimedia functionality and to decrease the performance (Havinga, 2000; Ong, Nahrstedt, & Yuan, 2003).

BASIC MOBILE DEVICE SECURITY

Vulnerability Analysis

Security risks associated with mobile devices are almost the inverse of the risks associated with desktop computers. Physical access to desktops can be controlled using physical access control mechanisms in form of guarded buildings and door locks. Electronic access can be controlled using personal firewalls. The physical access control and network intrusion protection mechanisms for desktop computers and wired networks are far away from complete. However, they are considered "good enough" and thus the most serious security concerns for desktop computers are related to data transmission between desktop computers. Mobile devices are small, portable, and thus easily lost or stolen. The most serious security threats with mobile devices are thus unauthorized access to data and credentials stored in the memory of the device.

Physical Access

Mobile phones and PDAs are small portable devices that are easily lost or stolen. Most platforms for mobile devices provide simple software-based login schemes for protecting device access with a password. Such systems can however easily be bypassed by reading information from the device memory without logging in to the operating system. This means that critical and confidential data stored unencrypted in the device memory is an easy target for an attacker who has physical access to the device (Symantec, 2003).

Malicious Software

Smartphones and PDAs have not actually been preferred targets for malware developers until 2004. On the time of writing, malware is still not the most serious security concern. However, the continuous increase of the number of mobile device users worldwide is changing the situation. Current malicious software is mainly focused on Symbian OS and Windows based devices. Malicious software in handheld devices may result in (Olzak, 2005):

- Loss of productivity;
- Exploitation of software vulnerabilities to gain access to recourses and data;
- Destruction of information stored on a SIM card; and/or
- Hi-jacking of air time resulting in increased costs.

Even though malicious software currently does not cause serious threats for the mobile device itself, they cause a threat for a computing network to which the mobile device is connected. Viruses are easily spread to an internal computer network from a mobile device over wireless connections such as infrared, Bluetooth, or WLAN.

Wireless Connection Vulnerabilities

Handheld devices are often connected to the Internet through wireless networks such as cellular mobile networks (GSM, GPRS, UMTS), WLANs, and Bluetooth networks. These networks are based on open air connections and are thus by their nature easy to access. Many Bluetooth networks and especially WLANs are still unprotected. This means that any device, within the network coverage, can access the wireless network. Furthermore, confidential data transmitted over an unprotected wireless network can easily be captured by an intruder.

Security Policy

Examples of security policy rules for mobile device end users as well as for administrators of mobile devices in corporate use are proposed (Taylor, 2004-2005, Part V):

- Make sure that the cell phone, PDA, or smartphone is password protected.
- Use secure remote access VPN to connect to the corporate network for the purpose of checking e-mail.
- Keep a firewall and an anti-virus client with up-to-date anti-virus signatures installed on the handheld if connecting the corporate network.
- Use the security policies on the handheld firewall that are recommended by the corporate security team.

Examples of rules proposed for corporate administrators of mobile devices (Taylor, 2004-2005, Part V):

- End users must first agree to the End-User Rules of Behavior.
- All handheld users are to be setup with a secure remote access VPN client to connect to the corporate network.
- Advice end-users what anti-virus client to use.
- Handheld firewalls are configured to log security events and send alerts to security_manager@company.com.
- Handheld groups and net groups are set up to restrict access privileges only to services and systems required.

Platform Security

The convergence between the fixed Internet and the mobile Internet has raised the question of security of mobile devices. The introduction of packet-based services, such as GPRS and 3G, has opened the wireless industry to new services, but also to new mobile device vulnerabilities. The handsets are actually changing from a formerly closed nature to a more open system. Incidents involving spamming, denial-of-services, virus attacks, content piracy, and malicious attacks have become a growing problem in the wireless world. With this openness a new level of security is required to protect wireless networks and handsets (Sundaresan, 2003).

Security is an integral part of a mobile handset because security affects all parts of the mobile device. Security issues can therefore not be treated as separate add-on features. Instead, security needs to be built into the platform (Trusted Computing Group, 2004).

Mobile Device Forensics

Computer forensics is the process of investigating data processing equipment—typically a PC computer but also mobile device like a PDA computer or a mobile smartphone—to determine if the equipment has been used for illegal, unauthorized, or unusual activities. Computer forensics is especially needed when a mobile device is found or returned after being lost or stolen in order to estimate if and what damage has occurred. By using specially designed forensics software, computer

experts are able to identify suspects and sources of evidence, to preserve and analyze evidence, and to present findings (Phillips, Nelson, Enfinger, & Steuart, 2005; Robbins, 2005).

Physical Protection

Physical security of a mobile device means protection against physical and electromagnetic damage, and protection of stored content against power failures and functional failures. There must be possibilities to recover stored content after damage, after a functional failure, or after an intrusion attack. Furthermore, protection of stored content in case of theft or other loss of the mobile device must be included.

Physical Damage

Most common physical damage is caused by a mechanical shock when the mobile device is dropped or by water when the mobile device has fallen into water or has been exposed to rain.

In case of a mechanical shock the content interface, the display and/or the keyboard, is usually damaged and the stored content is accessible after the content interface is repaired or the electronics and memory modules are transferred to another device. Water will cause damage to the power supply battery and also to electronic components.

Electromagnetic Damage and Unwanted Wireless Communication

The electronic and/or the stored content of a mobile device can be damaged by strong electromagnetic radiation. A switched-on mobile device may also have an always open wireless network connection. For prevention of unwanted electromagnetic radiation and unwanted wireless communication, an electromagnetic shielding bag (MobileCloak™ Web Portal, 2005) can be used.

Power and Functional Failures

The operating system should store configuration changes and sufficiently often, for example every five minutes, backup the working spaces of open applications in non-volatile memory in order to minimize the data losses in case of sudden power failure or other functional failure.

Backup and Recovery

Recovery after power failure or other functional failures is usually managed by the operating system from stored configuration data and from timed backups of the working spaces of open applications. A usual backup function of mobile devices is synchronization with a desktop computer. Examples of synchronization are HotSync in Palm OS, ActiveSync in Windows CE and Windows Mobile, and SyncML in Symbian OS. Recovery from a synchronization backup or from a traditional backup is needed after physical and electromagnetic damage and after an intrusion attack.

Loss and Theft

To minimize damage caused by a lost or stolen device, the following precaution measures are suggested:

- Confidentiality level classification of stored content;
- Content encryption of sensitive data;
- Use of bit wiping software, for stored content with the highest confidentiality level classification; and
- Visible ownership information, for example a phone number to call if a mobile device is found, for return of a lost or stolen mobile device.

Activated bit wiping software will permanently delete data and program code according to user

settings. Good bit wiping software will also delete all related information in working memory (RAM) and in plugged external memory cards. Bit wiping software is typically activated when a wrong device access password is entered a preset number of times and/or the mobile device is not synchronized within a preset timeframe. Because bit wiping software can also be triggered by accident, a fresh synchronization backup or a fresh traditional backup of the stored content should always be available.

Device Access Control

Physical access control mechanisms are ineffective for PDAs and smartphones since such devices are small, portable, and thus easily lost and stolen. Access control mechanisms on the device itself are thus important for protecting the data stored in the device. Currently, there are no widely adopted standards for access control services in mobile devices. Manufacturers are concentrating more on securing the communication protocols than securing stored data in the device. However, this trend is expected to change in the near future. The use of handheld devices is constantly growing, and thus the need for secure access control mechanisms is also increasing.

Access control on a mobile device can be implemented with a combination of security services and features (Perelson & Botha, 2004):

- Authentication service
- Confidentiality service
- Non-repudiation service
- Authorization

Primarily, the security services for access control are authentication and authorization services. The principle of access control on a mobile device is shown in Figure 1.

Authentication

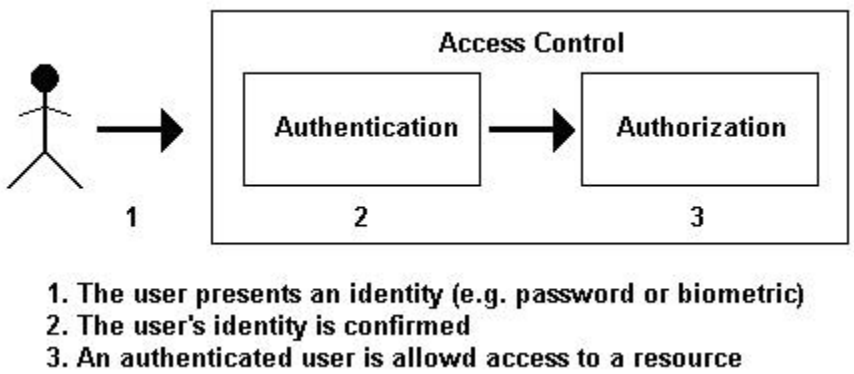
An authentication service is a system for confirming a claimed user identity. There are many methods in which a user is able to authenticate to a handheld device. These methods include:

- Passwords/PINs
- Visual and graphical login
- Biometrics

PIN and Password Authentication

Many handheld devices use a PIN code for user authentication. The PIN is four digits of length and is entered by the user from a ten-digit (0-9)

Figure 1. The principle of access control



numerical keypad. PINs are suitable for personal handheld devices, not containing critical information. However, PINs do not provide sufficient security for handheld devices in corporate use. PINs may be susceptible to shoulder surfing or to systematic trial-and-error attacks due to their limited length and alphabet. Passwords are more secure than PINs since they support a larger alphabet and increase the number of digits in the password string (Jansen, 2003).

Most PDA and smartphone operating systems provide inherent support for traditional alpha-numeric passwords. Strong password authentication solutions can also be implemented by installing additional security software, see section, *Available Security Solutions.*

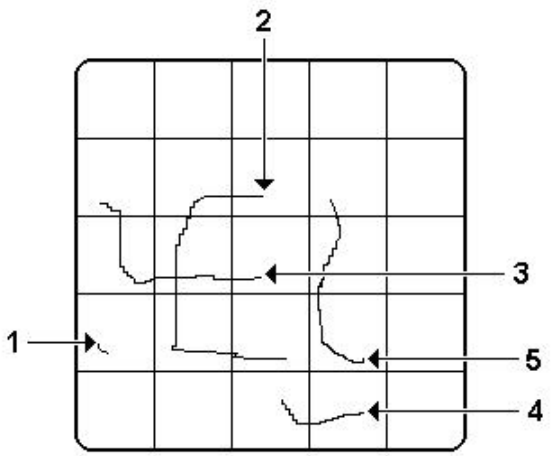
Visual and Graphical Login

Visual authentication allows a user to select a sequence of icons or photo images as a password value. Instead of alpha-numeric characters a user must remember image sequences from a list of pictures shown on the display of the device. A visual authentication method is more user-friendly and more secure than standard password authentication. In order for a password to be secure, it must consist of many digits including both upper and lower case characters as well as both characters and numbers. Picture combinations are for a user easier to remember than complex password strings. Furthermore, a picture password system can be designed to require a sequence of pictures or objects matching a certain criteria and not exactly the same pictures (Duncan, Akhtari, & Bradford, 2004).

Graphical login relies on the creation of graphical images to produce a password value. A user enrolls a password value by drawing a picture on a display grid including block text or graphical symbols. Login process strokes can start anywhere and go in any direction on the touch screen, but they must occur in the same sequence as in the enrolled picture. The system maps each continuous stroke to a sequence of coordinate pairs by listing all cells through which the stroke passes and the order in which the stroke crosses the cell boundaries. An example with a five-stroke password entry, which can be drawn in eight different ways, is shown in Figure 2. The authentication system controls the ordering of the strokes and the beginning and end point of each stroke. The numbered items in Figure 2 indicate in which order the strokes were drawn and point to the starting point of each stroke in the enrolled picture (Jansen, 2003).

Currently, there are no PDAs or smartphones providing inherent support for visual or graphi-

Figure 2. A five-stroke graphical password



cal login. To implement such an authentication method, an additional security application must be installed. Examples of such applications are presented in section, *Available Security Solutions.*

Biometrics

Biometric user authentication is a hardware solution for examining one or more physical attributes of an authorized user. Biometric controls are becoming more and more common in handheld devices (Perelson & Botha, 2004).

Fingerprint Verification

Fingerprint verification provides both user friendliness and security. A user only needs to touch a certain point of the handheld device in order to authenticate to it. The user does not need to remember a complex password string or an image sequence and the security level is still high since every fingerprint is unique.

Signature Verification

Signature verification is a technology where a number of dynamic characteristics from a physical signing process are captured and compared. Dynamic characteristics are speed, acceleration, direction, pressure, stroke length, sequential stroke pattern, and the time and distance when the pen is lifted away from the surface. The physical signature is made with an electronic pen on the touch screen (Jansen, 2003).

Voice Verification

In voice verification identifying and authenticating is based on the user's voice. The enrollment process is normally performed in a way that the user speaks a set of specific words. Usually this process is repeated several times. A template is then extracted from this voice input. This template defines the characteristics of the recorded voice. During authentication, the system prompts the user to pronounce a set of randomly chosen digits as they appear on the display of the handheld device (Jansen, 2003).

Voice verification for smartphones and PDAs has not yet broken through, but a number of companies have recently developed new biometric software and devices (Kharif, 2005).

Authorization

Handheld devices are typically personal and the authentication process infers that the user is authorized. It is often assumed that all data stored on a device is owned by the user. Today, there are large gaps in the features of the authorization services in both smartphone and PDA devices (Perelson & Botha, 2004).

It is becoming more common that handheld devices replace desktop and notebook computers in companies. A single device may be used by several employees and may contain confidential company information. Thus, the need for proper user authorization services is becoming more important. Such services are Perelson and Botha (2004):

- **File Masking:** Certain protected records are prevented from being viewed by unauthorized users.
- **Access Control Lists:** A list defines permissions for a particular object associated with a user.
- **Role-Based Access Control:** Permissions are defined in association with user roles.

Storage Protection

Storage protection of a mobile device includes online integrity control of all stored program code and data, optional confidentiality of stored user data, and protection against unauthorized tampering of stored content. Protection should

include all removable storage modules used by the mobile device.

The integrity of the operating system code, the program code of installed applications, and system and user data can be verified by using traditional tools like checksums, cyclic redundancy codes (CRC), hashes, message authentication codes (MAC, HMAC), and cryptographic signatures. Only hardware-based security solutions for protection of verification keys needed by MACs, HMACs, and signatures provide strong protection against tampering attacks, since a checksum, a CRC, and a hash of a tampered file can easily be updated by an attacker. Online integrity control of program and data files must be combined with online integrity control of the configuration of a mobile device. This is needed to give sufficient protection against attempts to enter malicious software like viruses, worms, and Trojans.

Required user data confidentiality can be granted by file encryption software. Such software also protects the integrity of the stored encrypted files, since successful decryption of an encrypted file is also an integrity proof.

Network and Network Service Access Control

Once a user is authenticated and granted access to the handheld device, the device can be connected to and used in several types of networks and network services. This section presents access control mechanisms and user authentication issues related to some of these systems.

Hardware Authentication Tokens

Hardware tokens are used in handheld devices to authenticate mobile end users to mobile networks and network services. Such hardware tokens are SIM (subscriber identity module), PKI SIM (public key infrastructure SIM), USIM (universal SIM) and ISIM (IP multimedia services identity module) chips.

SIM

A basic SIM card is a smartcard securely storing an authentication key identifying a GSM network user. The SIM card is technically a microcomputer, consisting of a CPU, ROM, RAM, EEPROM, and I/O (input/output) circuits. This microcomputer is able to perform operations, such as cryptographic calculations with the individual authentication key needed for authenticating the subscriber. The SIM card also contains storage space for SMS (short message services) messages, MMS (multimedia messaging system) messages, and a phone book. The use and content of a SIM card is protected by using PIN codes.

PKI SIM

A PKI SIM card is a basic SIM card with added PKI functionality. A co-processor is added to take care of decryption and signing with private keys. A PKI SIM card contains space for storing private keys for digital signatures and for decryption (Setec Portal, 2005).

PKI SIM cards open the possibility for handheld users to generate digital signatures and authenticate to online services. Currently, the use of PKI SIM cards is not widely supported. However, systems for utilizing this technique are being developed.

USIM

A USIM card is a SIM used in 3G mobile telephony networks, such as UMTS. USIM is based on a different type of hardware; it is actually an application running on a UICC (universal integrated circuit card). The USIM stores a pre-shared secret key as the basic SIM.

ISIM

An ISIM card consists of an application (ISIM) residing on a UICC. The ISIM application provides

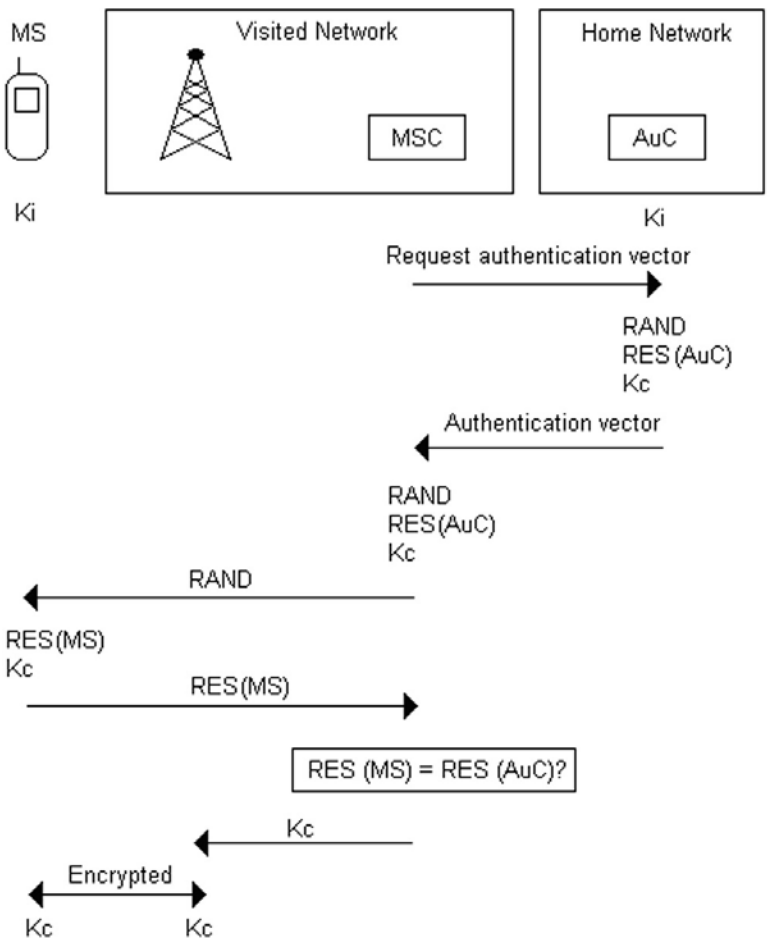
secure authentication of handheld users to IMS (IP multimedia systems) services (Dietze, 2005).

Cellular Networks

GSM/GPRS

User authentication in GSM networks is handled by a challenge-response based protocol. Every MS (mobile station) shares a secret key Ki with its home network. This key is stored in the SIM card of the MS and the AuC (Authentication Centre) of the home network. Ki is used to authenticate the MS to the visited GSM network and for generating session keys needed for encrypting the mobile communication. The authentication process, shown in Figure 3, is started by the MSC (Mobile Switching Centre) which requests an authentication vector from the AuC of the home network of the MS. The authentication vector, generated by the AuC, consists of a challenge response pair (RAND, RES) and an encryption key Kc. The MSC of the visited network sends the 128-bit RAND to the MS. Upon receiving the RAND, the MS computes a 32-bit response (RES) and an encryption key Kc using the received RAND and the Ki stored in the SIM. The MS sends the RES back to the MSC. MSC verifies the identity of the MS by comparing the received RES from the MS with the received RES from the AuC. If they

Figure 3. GSM authentication and key agreement



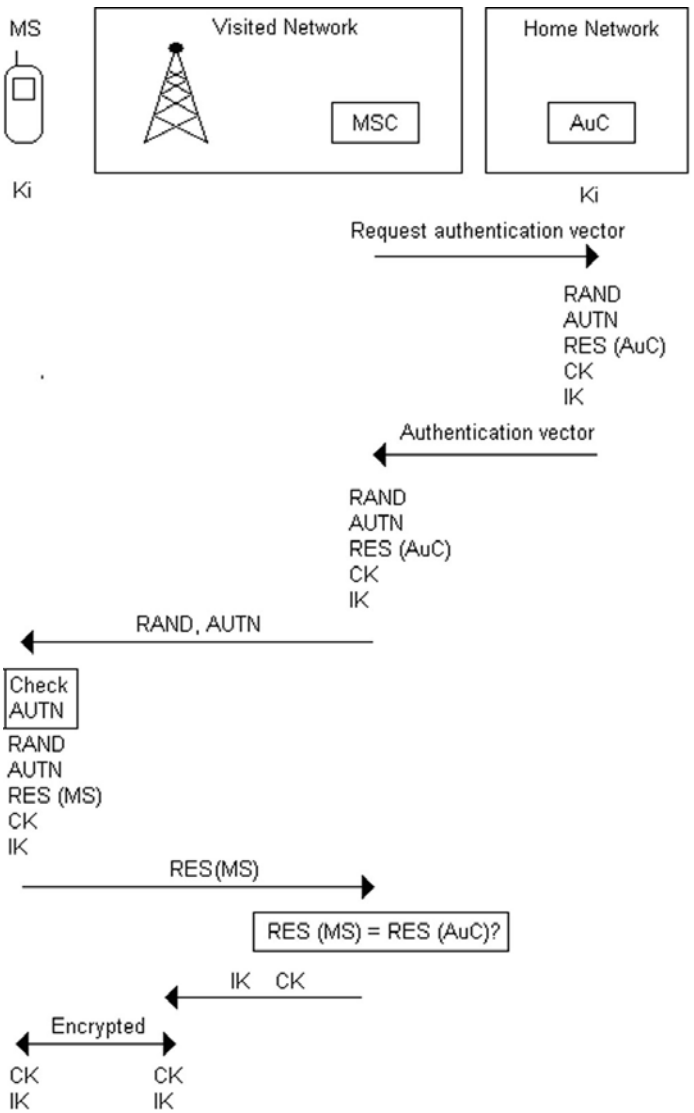
match, authentication is successful and the MSC sends the encryption key Kc to the base station serving the MS. Then the MS is granted access to the GSM network service and the communication between the MS and the base station is encrypted using Kc (Meyer & Wetzel, 2004).

GSM networks provide reasonably secure access control mechanisms. The most serious concern is the lack of mutual authentication. This opens a possibility for an attacker to setup a false base station and imitate a legitimate GSM network. As a result, the key Ki can be cracked and the attacker can then impersonate a legitimate user (GSM Security Portal, 2005).

UMTS

The authentication and key management technique used in UMTS networks is based on the same principles as in GSM networks (see Figure 4). A secret authentication key is shared between the network and the MS. This key is stored on the MS USIM

Figure 4. UMTS authentication and key agreement



and in the AuC of the home network. Unlike in GSM networks, UMTS networks provide mutual authentication. Not only MS is authenticated to the UMTS network but also the UMTS network is authenticated to MS. This protects MS from attackers trying to impersonate a valid network to the MS. Network authentication is provided by a so-called authentication token AUTN.

The MSC (Mobile Switching Centre) of the visited network sends the AUTN together with the authentication challenge to MS. Upon receiving the AUTN, containing a sequence number, the MS checks whether it is in the right range. If the sequence number is in the right range the MS has successfully authenticated the network and the authentication process can proceed. The MS computes an authentication response, here called RES, and encryption and integrity protection keys, called CK and IK, and sends these back to the MSC. The MSC verifies the identity of the MS by checking the correctness of the received RES. Upon successful authentication, the MSC sends the encryption key CK and integrity key IK to the UMTS base station. The MS is now able to communicate with the UMTS network and the communication between the MS and the base station is encrypted with CK and the integrity is protected with IK (Meyer & Wetzel, 2004).

Wireless Personal Area Networks

IrDA

The IrDA standard does not specify any security measures. However, since IrDA is a short line of sight-based connection, security threats can be eliminated by physical security measures.

Bluetooth

Bluetooth technology provides device authentication, not actually user authentication. The whole authentication process can be divided into two phases, an initial process called pairing and a mutual device authentication process.

Pairing

Two Bluetooth devices, that want to set up a connection, share a PIN code which is entered on both devices in the beginning of the pairing process. The PIN code, the address of the Bluetooth device, and a 128-bit random number is used as inputs to an algorithm (E1) for creating an initialization key. A new random value is generated on both devices and exchanged after XORing it with the initialization key. With this new 128-bit random value, and the Bluetooth device address, the common shared secret key, called link key, is generated using the E21 algorithm (Gehrmann et al., 2004; Xydis & Blake-Wilson, 2002).

Mutual Authentication

After pairing, the actual device authentication is performed through the use of a challenge-response scheme. One of the devices is the verifier and the other is called a claimant. The verifier generates a 128-bit challenge value. The claimant then uses the algorithm E1 with the challenge, its 48-bit Bluetooth address, and the link key as inputs, for creating a 128-bit value. The 32 most significant bits of this value are returned to the verifier. The verifier verifies the response word by performing the same calculations. If the response value is successful, then the verifier and the claimant change roles and repeat the authentication process (Gehrmann et al., 2004; Xydis et al., 2002).

Authorization

Bluetooth technology also offers a way of performing user authorization. Devices have two levels of trust. They are divided into trusted or untrusted devices. A device is trusted only when it first has been authenticated. Interplay of authentication and authorization defines three service levels (see Table 1) (Gehrmann et al., 2004).

At service level 3, any device is granted access to any service. At the next level, only authenticated

Table 1. Bluetooth service levels

	Authorization	Authentication	Encryption
Service Level 1	Yes	Yes	Yes
Service Level 2	No	Yes	Yes
Service Level 3	No	No	Yes

devices get access to all services, and at service level 1, only authenticated devices are granted access to one or more certain services.

Security Analysis

One of the major weaknesses in Bluetooth access control is the lack of support for user authentication. A malicious user can easily access network resources and services with a stolen device. Furthermore, PIN codes are often allowed to be short and thus susceptible to attacks. However, the coverage range of a Bluetooth network is very short. Malicious access to a Bluetooth network can therefore mostly be prevented by the use of physical access control measures.

Wireless Local Area Networks

Implementation and use of secure access control mechanisms is essential in order to protect WLANs from unauthorized network access. WLANs became, during their first years, known for their serious security vulnerabilities. One of the most significant concerns has been the lack of proper user authentication methods. Today, WLANs provide acceptable security through the recently ratified security standard IEEE 802.11i.

Access Control Based on IEEE 802.11

The authentication mechanisms defined in the original WLAN standard IEEE 802.11 are weak and not recommended. The standard only provides device authentication in form of the use of static shared secret keys, called WEP (wired equivalent privacy) keys. The same WEP key is shared between the WLAN access point and all authorized clients. WEP keys have turned out to be easily cracked. If a WEP key is cracked by an intruder, the intruder gets full access to the WLAN.

WEP authentication can be strengthened by using MAC filters and by disabling SSID broadcasting on the access point. However, SSIDs are easily determined by sniffing probe response frames from an access point and MAC address are easily captured and spoofed.

Access Control Based on IEEE 802.11i

The recently ratified WLAN security standards WPA and WPA2 address the vulnerabilities of WEP. WPA is a subset of the IEEE 802.11i standard, and WPA2 provides full 802.11i support. The difference between WPA and WPA2 is the way how the communication is encrypted. Furthermore, WPA2 provides support for ad-hoc networks which is missing in WPA. User authentication in WPA and WPA2 are based on the same techniques. Currently, there are already a number of PDAs and smartphones supporting WPA. WPA2, however, is still not supported in any handheld device (Wi-Fi Alliance Portal, 2005).

Pre-Shared Key. 802.11i provides two security modes: home mode and enterprise mode. The home mode is based on a shared secret string, called PSK (pre-shared key). Compared to WEP, PSK is never used directly as an input for data encryption algorithms. For large WLANs, the enterprise mode is recommended. The home mode is suitable for small WLAN environments, such as small office and home WLANs, where the number of users is small.

IEEE 802.1X. The enterprise security mode utilizes the IEEE 802.1X standard for user authentication. The 802.1X standard is designed to address open network access. Three different components are involved: supplicant (client), authenticator (WLAN access point) and AAA (authentication, authorization, and accounting) server. The supplicant wants to be authenticated and accesses the network via the authenticator. The AAA server, typically a RADIUS (remote authentication dial-in user service) server, works as a back-end server providing authentication service to an authenticator. The authentication server validates the identity and determines, from the credentials provided by the supplicant, whether the supplicant is authorized to access the WLAN or not.

The authenticator works as an intermediary between the supplicant and the authentication server passing authentication information messages between these entities. Until the supplicant is successfully authenticated on the authentication server, only authentication messages are permitted between the supplicant and the authentication server through the authenticator's uncontrolled port. The controlled port, through which the supplicant can access the network services, remains in *unauthorized state* (see Figure 5). As a result of successful authentication, the controlled port switches to *authorized state*, and the supplicant is permitted access to the network services (see Figure 6).

EAP (Extensible Authentication Protocol). 802.1X binds the EAP protocol which handles the exchange of authentication messages between the supplicant and the AAA server. The exchange is performed over the link layer, using device MAC addresses as destination addresses. A typical EAP authentication conversation between a supplicant and an AAA server is shown in Figure 7.

EAP supports the use of a number of authentication protocols, usually called EAP types. The following EAP types are WPA and WPA2 certified (Wi-Fi Alliance Portal, 2005):

- EAP-TLS (EAP-Transport Layer Security);
- EAP-TTLS (EAP-Tunneled Transport Layer Security);
- PEAPv0/EAP-MSCHAPv2 (Protected EAP version 0/EAP-Microsoft Challenge Authentication Protocol version 2);
- PEAPv1/EAP-GTC (PEAPv1/EAP-Generic Token Card); and
- EAP-SIM.

Figure 5. 802.1X authentication in unauthorized state

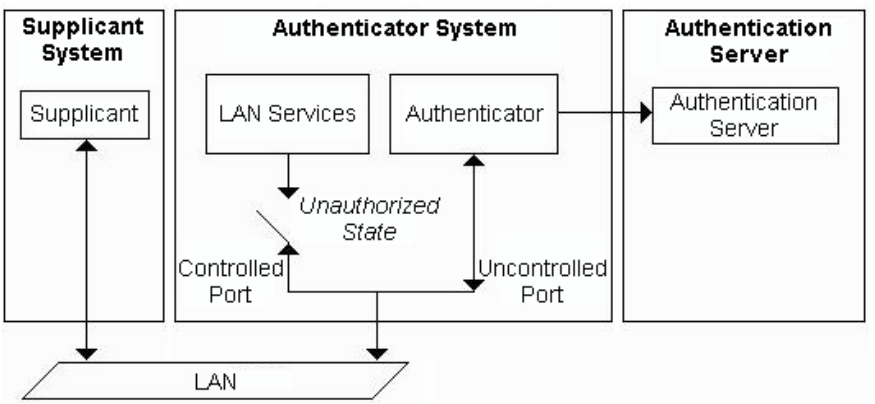


Figure 6. 802.1X authentication in authorized state

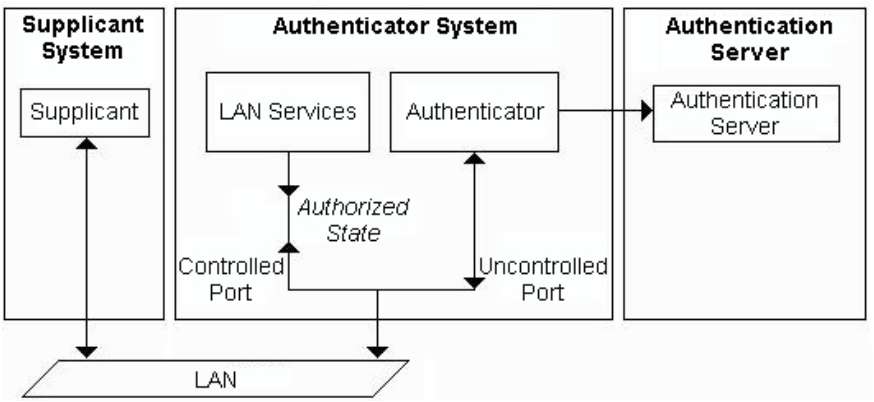

Figure 7. EAP authentication exchange messages

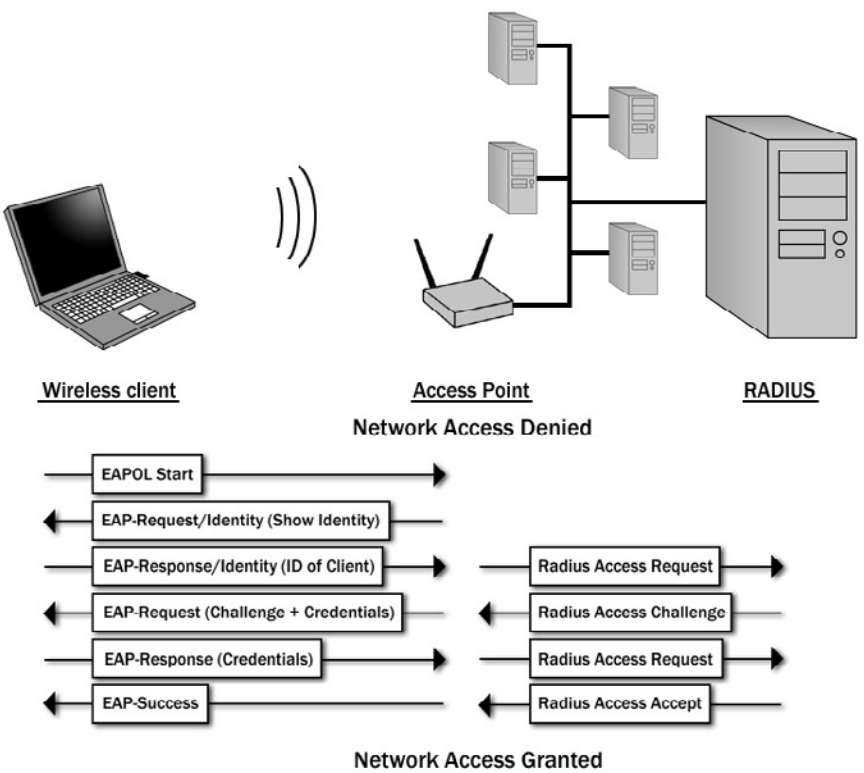

EAP-TLS, EAP-TTLS, and EAP-PEAP are based on PKI authentication. EAP-TTLS and EAP-PEAP however only use certificate authentication for authenticating the network to the user. User authentication is performed using less complex methods, such as user name and password. EAP-TLS provides mutual certificate based authentication between clients and authentication servers. Therefore, a X.509 based certificate is required both on the client and on the authentication server for user and server authentication (Domenech, 2003).

EAP-SIM is an emerging EAP authentication protocol. This standard is still an IETF draft. EAP-SIM is based on the existing GSM mobile phone authentication system. A user is able to authenticate to the network using the secret key and algorithms embedded on the SIM card. In order to implement EAP-SIM, a RADIUS server supporting EAP-SIM and equipped with a GSM/MAP/SS7 (GSM/Mobile Application Part/Signalling System 7) gateway is needed. Additionally, the client software must support the EAP-SIM authentication protocol. The RADIUS server contacts the user's home GSM operator through the GSM/MAP/SS7 gateway and retrieves the GSM triplets. The triplets are sent to the client via the access point, and if the supplicant and the user's SIM card are able to validate the GSM triplets, then the RADIUS server requests the access point to grant the client network access.

Network Connection Security

Connection security means:

- Integrity of communication;
- SIM, USIM, PKI SIM, ISIM cards in cellular mobile networks (GSM, GPRS, UMTS);
- Confidentiality of communication (SSH, VPN, SSL, voice, video);
- Intrusion prevention
    - traffic filtering (firewall)
    - firewall log of connection attempts;
- Malware rejection: Anti-virus software and anti-spyware;
- Mutual authentication of communicating partners;
- Security settings and commitment to security policy rules controlled by centralized security management software;
- Control of remote synchronization (Palm OS/HotSync, Windows CE & Windows Mobile/ActiveSync, Symbian OS/SyncML based);
- Security audits based on communication event logging, analysis of logged information, alerts, and alarms; and
- Shielding the mobile device from unwanted wireless communication.

Basic Communication Security

Basic communication security of a mobile device can be defined as intrusion prevention and malware rejection. The basic intrusion prevention tool is a configurable firewall with communication event logging and alert messaging. The basic malware rejection tools are anti-virus and anti-spyware with suspicious event alarming features. The core of a malware rejection tool is a malware recognition database. Malware rejection tool providers constantly update this database and the updated malware recognition database is available to users through some network connection. An installed malware rejection tool should always use the latest update of the malware recognition database. Anti-virus software for mobile devices is delivered for example by Symantec Corporation (2005) and Kaspersky (2007).

Authentic Data Communication

Authentic data communication is based on mutual authentication of communicating parties. In 2G cellular networks (GSM Data) authentication is uni-directional. The mobile device is authenticated to the cellular network by use of the shared secret

key in the SIM card. Mutual authentication, for example, based on a public key certificate, is however possible for packet data communication in GSM networks (GPRS) in addition to PIN-based GSM authentication. In 3G cellular networks, like UMTS, authentication is mutual. The mobile device and the network are authenticated to each other by the authentication and key agreement (AKA) mechanism (Cremonini, Damiani, De Capitani di Vimercati, Samarati, Corallo, & Elia, 2005).

In a WLAN authentication is mutual for WPA and IEEE 802.11i (WPA2). The authentication of a mobile client is based on presented credentials and information registered in an AAA server. The authentication protocol, EAP, also requires authentication of the AAA server to the mobile client (Pulkkis, Grahn, Karlsson, Martikainen, & Daniel, 2005). Also a Bluetooth connection can be configured for mutual authentication. The default security level of a Bluetooth service is:

- **Incoming Connection:** Authorisation and authentication required.
- **Outgoing Connection:** Authentication required (Muller, 1999).

Integrity and Confidentiality of Data Communication

Confidentiality and integrity of all data communication to and from cellular mobile networks (GSM, GPRS, UMTS) is provided by the security hardware of SIM/USIM/PKI SIM/ISIM cards in mobile devices.

For data communication through other network types (WLAN, Bluetooth, IrDA) connection specific security solutions must be installed, configured, and activated. Alternatively, end-to-end security software like VPN and SSH must be used. Available PDA VPN products are listed in (Taylor, 2004-2005, Part IV).

For WLAN connections, available solutions for confidentiality and integrity of all data communication are WEP, WPA, and IEEE 802.11i (WPA2). WEP security is however weak, since WEP protection can be cracked from recorded WEP protected data communication (WEPCrack, 2007).

For Bluetooth connections link-level security corresponding to security mode 3 should be used (Sun, Howie, Koivisto, & Sauvola, 2001a).

Roaming Security

Widely accepted Internet protocol standards supporting roaming for mobile devices are Mobile IP (Perkins, 2002) and SIP (Rosenberg et al., 2002). Mobile IP supports network level roaming, which is transparent for all IP-based network applications. SIP supports application level roaming, mainly for multimedia streaming services. Roaming security means:

- mutual authentication of a mobile device and the access network;
- integrity protection and confidentiality of all data communication, including roaming control signaling in handover situations.

A mobile device with Mobile IP support has an IP address registered by a home agent in the home network. A roaming mobile device visiting a new foreign network is registered with an additional IP address, the care-of-address by a foreign agent in the visited network and also by the home agent. The home agent can then redirect IP packets with the home address of the mobile node to the foreign network, which is presently visited by the mobile node. Home and foreign agent functionality is usually implemented on the gateway router of a network.

Authentication services for the Mobile IP protocol are:

- Security associations for authentication of mobile device registration messages (Rosenberg et al., 2002);

- AAA server based authentication of the home agent and the foreign agent of a mobile device (Calhoun, Johansson, Perkins, Hiller, & McCann, 2005; Glass, Hiller, Jacobs, & Perkins, 2000); and
- Public key cryptography based authentication of a mobile device (Hwu, Chen, & Lin, 2006; Lee, Choi, Kim, Sohn, & Park, 2003).

Secure Mobile IP communication in a handover situation can be achieved:

- on data link level by the WLAN security protocol WPA or IEEE 802.11i, when the new access network is a WLAN;
- as end-to-end protection by the security protocols IPSec, SSL, SSH, or by mobile node identity based public key cryptography (Barun & Danzeisen, 2001; Hwu, Chen, & Lin, 2006; Islam, 2005).

Security of SIP supported mobile device roaming is described in the section, *Mobile Multimedia Security.*

Connection Security Management

Security settings and commitment to security policy rules should be controlled by centralized security management software. Security audits based on communication event logging, analysis of logged information, and on alerts and alarms should be performed with timed and manual options.

Special attention should be paid to control of remote synchronization (Palm OS/HotSync, Windows CE & Windows Mobile/ActiveSync, Symbian OS/SyncML based). Remote synchronization should be disabled when not needed. Desktop and laptop computers should have basic communication security features like personal firewalls, anti-malware protection software with updated malware recognition data and latest software patches installed.

Use and attempts to use remote synchronization ports (see Table 2) should be logged and alerts and alarms should be triggered by unauthorized use or usage attempts. Passwords used by synchronization software in desktop and laptop computers should resist dictionary attacks and the PC/Windows option to save connection passwords should not be used.

SECURITY OF MULTIMEDIA NETWORK APPLICATIONS

Security requirements for multimedia network applications and approaches to fulfill these requirements are surveyed in Sun, Howie, Koivisto, and Sauvola (2001b). The requirements include authentication, availability, protection, and performance.

Authentication Requirements

Authentication requirements for secure multimedia network applications are source authentication, receiver authentication, and authentication of delivered content.

Receiver authentication means that a user of a multimedia service must identify himself/herself with a password, by proving the possession of a

Table 2. TCP and UDP ports used by synchronization software

	TCP Ports Used	UDP Ports Used
ActiveSync	990, 999, 5678, 5679	
HotSync	14237, 14238	14237
SyncML based	80 (http)	

security token, or biometrically before he/she is authorized for the service. Source authentication usually means that a user of a multimedia service checks the possession of a security token for the server or the provider before using the service. Digital signing and watermarking techniques can be used for authentication of delivered content.

A digital watermark is an imperceptible signal, which can be inserted into a digital content—a document, an image, an audio file/stream, a video file/stream, and so forth—for purposes like copyright control and binding digital content to content owners. Watermarks resist tampering and are robust to signal transformations like file filtering and compression. Content copyright and ownership can be checked with special watermark reading software. Digital pirates can be forensically revealed by watermark checks. A special type of watermarks, called annotation watermarks, can be used for access control based on binding usage rights to digital content. However, the current state of watermarking technology is imperfect. A hacker knowing the used watermark technique can often tamper watermarks beyond recognition (Cox & Miller, 1997; Dittmann, Wohlmacher, & Ackermann, 2001; Liu, Reihaneh, & Sheppard, 2003; Stamp; 2002).

Availability Requirements

Delivery of multimedia content to authorized receivers must be granted. Granted delivery of streaming multimedia implies quality of service (QoS) requirements, which include sufficient bandwidth from source to receiver for successful real-time content transport.

Requirements on IP for granted content delivery to authorized receivers are secure routing and DNS security. A misconfigured, faulty, or tampered router misdirects multimedia content transport and a fake DNS gives an incorrect IP address of the receiver.

Protection Requirements

Delivered multimedia content must protected against tampering, capture, unauthorized copying, and denial-of-service (DoS) attacks. With methods based on encryption, digital signing, and watermarking, some protection can be achieved.

Performance Requirements

Multimedia network applications usually generate and transmit a waste amount of data. Some multimedia applications, like interactive multipoint video streams, must also meet real-time constraints. Cryptographic operations needed by security services are therefore associated with strict execution time constraints, which can be met only by hardware implemented cryptographic algorithms. Also the complexity and specific characteristics of video coding technologies require careful choice as well as special design and application of cryptographic algorithms in necessary security services.

Secure Multimedia Streaming Services

For streaming service sessions both the session setup SIP signaling and the media transport should be protected. Security mechanisms in SIP for authentication of SIP user agent clients and confidential end-to-end and hop-to-hop communication are surveyed in Salsano, Veltri, and Papalilo (2002).

Streaming content delivery can be protected with the Secure Real-time Transport Protocol (SRTP) (Baugher, McGrew, Naslund, Carrara, & Norrman, 2004), which can provide confidentiality, message authentication, and reply protection to the RTP traffic and to the control traffic for RTP, the Real-time Transport Control Protocol (RTCP), which provides out-of-band control information

for an RTP flow (Schulzrinne et al., 2003). RTPC cooperates with RTP in the delivery and packaging of multimedia data, but the protocol does not actually transport any data itself. The function of RTCP is to gather statistics on a media connection and also information such as bytes sent, packets sent, lost packets, jitter, feedback, and round trip delay. An application may then use this information to increase the QoS. SRTCP (secure real-time transport control protocol) is a security protocol designed to provide the same security-related features to RTCP, as the ones provided by SRTP to RTP.

RTP does not provide any QoS guarantee. QoS can, however, be achieved using resource reservation techniques in the network. An example of such a technique is defined in RSVP (resource reservation protocol) (Braden, Zhang, Berson, Herzog, & Jamin, 1997; Featherstone & Zhang, 2004).

The RTP protocol itself is not suitable for integrated heterogeneous network environments consisting of both wired and wireless networks. As a solution for this weakness, mixers have been added to the RTP solution. The mixers are using a process called transcoding in order to deal with different levels of bandwidth. The transcoding process translates an incoming data stream into a different one with possible lower data-rate.

The use of mixers and translators to perform transcoding processes to achieve mobility support compromises security for example in video conferencing systems. Mixers and translators must decrypt data in order to be able to manipulate the data. After manipulation, the data streams are again re-encrypted. Thus, end-to-end confidentiality is compromised and furthermore since the data has been altered, it is impossible to perform source authentication.

The RSVP provides an authentication technique called hop-by-hop authentication (Baker, Lindell, & Talwar, 2000). This technique has however a high overhead, and is thus not suited for use in wireless networks with limited bandwidth. The hop-by-hop authentication in RSVP does furthermore not provide any key management or confidentiality services. This means that a separate key distribution algorithm is needed prior to the start of a conference and an attacker, who is eavesdropping the resource reservation messages could infer useful and sensitive information.

A solution to address security concerns with RSVP is proposed in RSVP-SQoS (RSVP with scalable QoS protection) (Talwar & Nahrstedt, 2000). This solution makes the design scalable by dividing a network into different sub-networks and it assumes that security requirements within one sub-network are weaker than the requirements for inter-sub-networks. Immediately, when a security violation is detected, the resource reservation is removed. However, considering mobile multimedia streaming services, this solution is not suitable since user mobility is not taken into account.

An end-to-end authentication scheme for resource reservation designed to eliminate DoS attacks, where an attacker alters the amount of resource requests, is worked out in Wu, Wu, Huang, and Gong (1999). In this solution, a digitally signed request is sent to the receiver by the source of the data stream. The digital signature is generated with the source's private key. If the receiver is able to verify the signed request, then it sends out a resource reservation message, which is a piggybacked version of the original request from the source, and a resource reservation request. These are also digitally signed before sent. As this message is sent back along the network, intermediate routers check if the piggybacked message is equivalent to the original one and when the message arrives back to the sender, the sender checks the signature of the packet. If any of these checks fail, the resource reservation is rejected. This protocol has, however, two major weaknesses. The first one is that it does not provide confidentiality to the reservation message. A potential attacker can thus eavesdrop on the messages. The second major weakness is that it lacks any support for mobility.

MOBILE MULTIMEDIA SECURITY

A mobile device for multimedia applications must fulfill the specific security requirements of mobile multimedia in addition to:

- all basic security requirements of mobile data communication; and
- all security requirements of multimedia network applications.

Security requirements of multimedia processing are included in the framework model of mobile security in Zeng, Zhuang, and Lan (2004).

A mobile device for multimedia applications should support:

- SIP signaling based application level mobility for multimedia streaming services; and
- Mobile IP-based network level mobility for file download services and carousel services for text and images.

Mobil IP functionality with security mechanisms described in the section, *Network Connection Security*, as well as SIP user agent functionality with security mechanisms surveyed in Salsano et al. (2002) should thus be integrated in secure mobile devices for multimedia applications. SIP signaling can during inter-domain roaming be separated from other network traffic by domain edge routers (Nasir & Mah-Rukh, 2006).

SRTP (Baugher et al., 2004) is used to encrypt the video, audio, or data stream for securing a multimedia streaming service, since real-time media transport is based on RTP and UDP. Setting up a secured session with SIP signaling involves exchange of separate SRTP key between the mobile device and the host delivering the stream for the specific media type (Dutta et al., 2004a).

Mobile Multimedia Device Security Based on IPSec VPN Technology

Mobile device security based on a IPSec VPN architecture is proposed for mobile multimedia services in a MAN network in Zhang, Lambertsen, and Yamada (2003). Bandwidth requirements of multimedia services are provided by a PON (passive optical network) backbone access network, which allows IP multicasting through optical fibres to a group of adjacent wireless base stations implemented by optical network units (ONU). The PON gateway to the Internet is an optical line terminal (OLT). An IPSec VPN agent with a VPN tunnel to the home network of the mobile devices is installed on this OLT. A mobile device entering the MAN is registered by the VPN agent, which also records the multicast address a roaming domain consisting of some adjacent ONU base stations. The location information of the mobile device is also updated in the VPN server in the home network of the mobile device. Smooth handover of IP multicast communication is now possible even if the mobile device roams rapidly between the ONU base stations. The privacy of the mobile device and the communication between the mobile device and the VPN agent can be protected by another IPSec VPN tunnel. The SAs and the VPN tunnel must not be renegotiated when the mobile device roams to another ONU base station, but the radio channel to the new ONU must be recreated and the location information of the mobile device must be updated at the VPN agent and at two ONUs. A correspondent C can now use the IP address in the home network of a mobile device. The VPN server in the home network can redirect the IP packets to the visited MAN network through the VPN tunnel to the VPN agent, which forwards the packets—unencrypted, pre-shared key encrypted, or ESP encrypted in another VPN tunnel—to the mobile device through the registered ONU.

Secure Mobile Video Conferencing

Video conferencing is one of the proposed future multimedia applications for mobile handheld devices. In a video conferencing system one or more data streams must be delivered to a client device in real time. The data streams may consist of video, audio, or other types of multimedia data. Two or more participants are taking part in a conference and the participants may want to have security provisions to protect their communication. For a mobile video conferencing system, where one or more of the participants are mobile, there are many challenging security issues:

- Implementing security with minimal loss of processing power;
- Implementing integrity and authentication algorithms, where authentication will not fail because of single bit errors caused by disturbances or disconnections in a wireless network;
- Roaming support;
- Protecting video streams from interception and interference; and
- Providing security for multicast multimedia data.

Security solutions for mobile multimedia video conferencing systems are under ongoing research. An example of such a research project is presented in Featherstone and Zhang (2003). The project started with studies of limitations and requirements for implementing security in mobile video conferencing environments. Related work was investigated to find out how current solutions can be improved to meet the requirements.

The requirements for mobile video conferencing can, according to the research project presented in Featherstone and Zhang (2003), be divided into three categories:

- Performance requirements
- Functional requirements
- Security requirements

Performance Requirements

Performance requirements of a mobile video conferencing system include QoS (quality of service) provision, minimal overheads, and accommodating heterogeneous network technologies. Real-time data needs bounded response times. Thus, bandwidth always needs to be guaranteed, also when a user is roaming between two mobile networks. A video conferencing system with implemented security and QoS provision introduces extra overhead to the system and also consumes extra bandwidth. These parameters need to be minimized in order to maintain QoS provision. Current and also future communication systems integrate both wired and wireless access networks of different standards. Thus, a video conferencing system design must be independent of underlying network technologies.

Functional Requirements

A video conferencing system should include at least the following functions:

- Initiation of a conference;
- Finishing of a conference;
- Admitting people to a conference;
- Allow someone to leave a conference;
- Deal with unexpected departure of a member from a conference;
- Split a conference;
- Merge two or more conferences; and
- Temporarily suspend a member from a conference.

Security Requirements

Security requirements in a mobile video conferencing system include:

- Confidentiality of the multiple multimedia data streams generated by a conference system;

- Integrity of multimedia data;
- Authentication of each member of a conference;
- Anonymity service for preventing outsiders from knowing that a conference is taking or has taken place;
- Non-repudiation service for providing evidence that a particular conference has actually taken place;
- Efficient and effective key exchange process for providing key distribution in a multicast environment;
- End-to-end protection; and
- Flexible security services providing users the possibility to choose different levels of protection.

CURRENT MOBILE MULTIMEDIA RESEARCH

The purpose of this section is to provide a picture of current and future trends in mobile multimedia security research. The research area is wide, and there is a large amount of ongoing research projects. Therefore, this section will only concentrate on a few important areas, such as secure roaming and video conferencing. A few examples of related research projects are presented. A testbed for developing and testing secure mobile multimedia systems is also presented.

Proposals for Secure Roaming

The current trend in mobile networking is towards mobile devices having multiple network interfaces such as WLAN, UMTS, and GPRS. A mobile user may want to securely and continuously access an enterprise network as well as securely receive real-time data such as multimedia data streams regardless of whether the user is physically located in the enterprise or not. The user should also be able to seamlessly roam between different types of wireless networks and still maintain an one-going secure application session. In order for a user to access an enterprise network from an external network it is typically required to use VPN technique. Using VPN, the enterprise network is able to authenticate the user and to determine whether the user should be permitted to use enterprise network applications or not. A key issue in developing a mobile multimedia system supporting seamless and secure roaming across heterogeneous radio systems is how to fulfill the security requirements and at the same time maintain QoS.

Current VPN technologies, such as IPSec, do not have sufficient capabilities to support seamless mobility. For instance, an IPSec tunnel will break when a mobile device changes its IP address as a result of roaming between two networks. Researchers are currently developing a new version of IKE (Internet Key Exchange), IKEv2, also known as MOBIKE. This version adds a mobility extension to the IKE protocol. The current MOBIKE specification is available as an IETF Internet-draft (Kivinen & Tschofenig, 2006). However, the work is still in a quite early stage. Another problem with VPN and mobility is that the VPN establishment requires manual actions from users when a time-variant password is used to set up the VPN. Furthermore, a VPN may cause significant overhead.

Roaming Based on Mobile IP and SIP

A secure universal mobility (SUM) network has been proposed (Dutta et al., 2004a). The network is able to support seamless mobility and the mobile user does not need to maintain an always-on VPN session. The SIP protocol can be used to achieve dynamic VPN establishment and Mobile IP for mobility support. A dynamic VPN is achieved by using a double tunneled Mobile IP. This Mobile IP system needs two home agents, an internal home agent, and an external home agent. One tunnel is set up from the mobile device to the external home agent and another tunnel is set up from the

external home agent to the internal home agent. When both tunnels are up, a corresponding node or a mobile user is able to initiate a communication by sending a SIP INVITE message. The receiver then checks if there is an existing VPN session. If not, IKE is used to negotiate security parameters and establish a new VPN session.

A testbed realization of secure universal mobility is also presented. Testbed experiments proved that smooth handoff is achieved during roaming between heterogeneous networks. However, an additional delay appeared while moving from a 802.11 network to a cellular network. VoIP and video streaming traffic was also tested.

Host Identity Protocol

When the current Internet architecture was designed, functionalities such as mobility and multi-homing were not taken into account. An IP address represents both an identity and a topological location of the host. This overloading has led to several security problems, such as the so-called address ownership problem (Nikander, 2001). This makes IP mobility and multi-homing hard from the security point of view.

A new protocol, HIP (host identity protocol) is currently under development and the current specifications are available as an IETF draft (Moskowitz & Nikander, 2006). In the HIP architecture, the locators and end-point identifiers are separated from each other at the network layer of the TCP/IP stack. A new cryptographic name space, the HI (host identity) is introduced, which is typically a cryptographic public key. This key serves as the end-point identifier of a network node. The IP address retains the role of a locator. Each host has at least one HI assigned to its networking kernel or stack. The HIs can be either public or anonymous. Public HIs may be stored in directories, such as DNS, allowing the host to be contacted by other hosts. In other words, HIP provides a binding between the HIs and the IP addresses using DNS.

The major advantages of the HIP architecture are that the problems of dynamic readdressing, anonymity, and authentication are solved. In HIP, the IP address has no longer the function of an end-point identifier. This significantly simplifies mobility since the node may easily change its HI and IP address bindings while moving. Furthermore, the security is improved since the name space is cryptographically based and it is thus possible to perform public key-based authentication using the HIs.

For further reading about the HIP protocol and HIP-related research projects, see Lundberg and Candolin (2003), Nikander, Ylitalo, and Wall (2003), and Helsinki University of Technology (2006).

Research Issues for Mobile Video Conferencing

Based on the analysis of current work in Featherstone and Zhang (2003), three major research issues for developing security and QoS provision in video conferencing systems for mobile computers were identified:

- **Mobility:** A satisfactory solution should provide a seamless QoS with mobility support and addressing of both wireless and wired networks.
- **Integrated Wired and Wireless Network:** Most mobile resource reservation schemes do not consider how QoS provision for wireless networks integrates with QoS provision on wired networks.
- **Security:** Systems providing both secure resource reservations as well as support for mobility are missing.

Testbed for Secure Mobile Multimedia

In Dutta et al. (2004b), a wireless Internet telephony and streaming multimedia testbed is set

up based on a testbed framework discussed in Dutta, Chen, Madhani, McAuley, NakaJima, and Schulzrinne (2001). Two types of mobility approaches are discussed: network-layer mobility by Mobile IP and application-layer mobility using SIP mobility. A moving mobile device is a target of potential attacks in different parts of the access and core network. Thus, a multi-layer security scheme is needed for providing comprehensive solutions that can possibly prevent any such attack and for supporting a dependable and secured multimedia application.

The testbed presented in Dutta et al. (2004b) is using an AAA protocol running on NAS (network access servers) and AAA servers to provide profile-based verification services. Additionally, a new protocol, PANA (protocol for carrying authentication for network access) (Yegin et al. 2005), is used for providing user-to-network access control. PANA provides access control mechanism to the mobile client and works as a front-end for the AAA server. It is implemented as a user level protocol to enable a flexible access control that works independently of any IPv4 or IPv6 layer 2 technology.

SIP-AAA Security Model

In the testbed two different security models were implemented. The first model is based on SIP and AAA and it was implemented in order to realize how SIP signaling can interact with an AAA infrastructure in a mobile environment. When the SIP server receives an SIP register message from the mobile device, it consults with the home AAA server for authentication and authorization. The profile verification database of the user is located in the home AAA server. In other words, in this model SIP registration is authenticated only after consulting with the AAA server. Normally, SIP registration is performed at the SIP server after the client has obtained a new address. The intention of the interaction between the SIP and the AAA server is to provide secure monitoring of user activities for accounting and auditing purposes.

IPSec-PANA-AAA Security Model

The second model, based on PANA and AAA, helps access control on the edge routers and interacts with IPSec to provide packet encryption. This model is a proposed multi-layered security scheme which provides packet-based encryption and application-layer authentication based on user NAI (network access identifier). In this model, PANA registration with the PANA server in the domain is performed when a user is roaming to a new network domain. In order to authenticate the user, the PANA server consults with the home AAA server either directly or indirectly through a local AAA server. As a result of successful PANA registration, an LSA (local security association) is established between the mobile device and the PANA server. Hereby, any further authentication required for intra-domain handoff is performed locally and quickly at the PANA server without the need to contact the home AAA server. The local authentication is also performed periodically with the intention to detect the event that the user disappears from the domain due to, for example, bad radio conditions.

The PANA server at the ERC (edge router & controller) maintains an association between the user identity, such as a NAI, and the lower-layer identity, such as an IP-address, for each user. The ERC has firewall functionality preventing packets sent from/to a mobile host not belonging to an authorized user to pass through the firewall. As a result of handoff, the association between the user identity and lower-layer identity dynamically changes. The ERC updates the access control list of the firewall if there is a change in the association and the resulting PANA registration or local authentication is successful. This prevents SIP register or SIP re-invite messages to pass through the firewall until the access control list is updated in the edge router.

In other words, PANA is used in the testbed to provide dynamic control of a router with firewall functionalities. Full network access is authorized only for hosts associated with authenticated PANA clients. An open firewall is closed immediately as a result of a failure of a periodical PANA re-authentication.

Packet Encryption and End-to-End Security

An IPSec-based encryption mechanism is used to secure data packets on the last hop in wireless networks. An IPSec tunnel is set up between the mobile client and the edge router. The PANA protocol is used for distributing IKE credentials to an authorized host. At first, the mobile client is authorized by PANA-based authentication. Then, the IKE credentials are carried in a PANA message and are transferred from the PANA authentication agent to the mobile client. These credentials are then used for setting up an IPSec tunnel between the mobile client and the access router. This provides a secure uni-cast communication channel in the access network including a wireless LAN segment. Since there is no need for a host to pre-configure the IKE credentials due to the dynamic distribution of the IKE credentials, mobile clients are enabled to smoothly roam among different domains.

In a mobile multimedia system it is essential to provide end-to-end security for both data and signaling. A combination of Mobile IP and IPSec solutions can be used to provide such an architecture, but such a combination is however not suitable for mobile systems since it will cause large overhead.

Real-time traffic is based on RTP/UDP. Thus, SRTP is used to provide encryption to different types of multimedia data. A secured RTP session requires the exchange of a separate RTP key between the mobile client and the correspondent host for a specific real-time media type. While registering with the SIP servers, SIP clients use PGP based authentication. The RTP key exchange is performed by an INVITE-exchange method using SIP signaling at the time of setting up calls. The RTP key is protected using a S/MIME mechanism. By these procedures, both data and signaling can be end-to-end secured without suffering from extra overhead.

CONCLUSIONS

Mobility and wireless communications introduce for multimedia applications similar problems with respect to security as for other applications. Advanced mobile terminals face new threats due to openness. Platforms are open for external software and content. Malicious software, like Trojan horses, viruses, and worms, has started to emerge. Fine-grained software authorisation has been proposed. Downloaded software may then access particular resources only through user authorisation. Vulnerabilities in OS implementation still remain a challenge because of difficulties in minimizing OS code running in privileged mode. Integrated hardware may be the solution.

Security aspects must be taken into account from the very beginning of the design of a mobile device for multimedia applications, not added on later. Security standards (SIP, secure RTP), technologies (IPSec) and testbed solutions for mobile multimedia are available, but significant improvements are still needed before acceptable security for mobile multimedia devices is achieved. Especially secure mobile video conferencing is still a research challenge.

APPENDIX: AVAILABLE SECURITY SOLUTIONS

Market offers several products as a solution to the increasing security problems of mobile devices. These products are designed to solve individual or more comprehensive security problems like unauthorized access to data or device, viruses, and unencrypted data transfers. The following list of the product groups reveal versatility of the mobile device security solutions (Douglas, 2004; Taylor, 2004, part III):

- Platform security products
- Authentication products
- Encryption products
- Anti-virus products
- Bit wiping products
- Firewall products
- VPN products
- Wireless security products
- Forensic products
- Database security products
- Centralized security management products
- Backup/restore products

In this section, available software products for platform security, authentication, encryption, anti-virus, VPNs (virtual private networks), firewall, and computer forensics are presented. The specific features of some products from each category are briefly described. In addition, characteristics and benefits of three well-known multifunctional security products for mobile devices, Pointsec, Bluefire and PDASecure, will be handled. Product information was searched during spring 2005.

Platform Security Solutions

There are different embedded on-chip security solutions, but mostly the security solution relies on a combination of hardware and software components. In the following, the two new security solutions, Texas Instruments OMAPTM Platform (Sundaresan, 2003) and Intel Wireless Trusted Platform (Intel, 2004), are shortly described.

The TI solution relies on three layers of security: application layer security, operating system layer security, and on-chip hardware security. The platform includes four main security features:

- **Secure Environment:** This feature enables secure execution of critical code and data. Sensitive information is hidden from the outside world with the use of four security components. These are *secure mode*, *secure keys*, *secure ROM*, and *secure RAM*. Secure mode allows secure execution of "trusted" code via on-chip authentication. Secure mode can be seen as a 3rd privilege level. Secure keys, ROM, and RAM are accessible only in secure mode. The keys are OEM specific one-time programmable keys used for authentication and encryption. Secure ROM is a storage feature using secure keys, key management and cryptographic libraries. Secure RAM is used for running OEM specific authenticated code.
- **Secure Boot/Flash:** The secure boot/flash process prevents security attacks during device flashing and booting. The authentication process must guarantee the origin and the integrity of the software stored on the platform. The process also prevents execu-

tion of any spoofed software code.

- **Run-Time Security:** The secure environment has been integrated into the OS. Thus, OS applications for short security critical tasks can be performed. Such tasks include encryption/decryption, authentication, and secure data management.
- **Crypto Engine:** Hardware crypto engines are used to enhance performance and security. Available crypto engines are DES/3DES, SHA1/MD5, and RNG. Two configuration modes are available: secure mode for short and/or high security level applications, and user mode for long and/or low-level security applications.

The building blocks of the Intel platform consists of performance primitives (hardware) and cryptographic primitives (optimized software). The solution enables services such as trusted boot and safe processing of secrets, protected key storage, and attestation measuring the security status of the platform during trusted boot.

The components of the platform include:

- **Trusted Boot ROM:** Validates the integrity of the platform and boots it into the right configuration.
- **Wireless Trusted Module:** This is the module where the secrets are processed. This suite of cryptographic engines include random number generation, symmetric and asymmetric cryptography, key creation, key exchange, digital signature operations, hashing, binding, and a monotonic counter.
- **Security Software:** A security software stack enables the OS and applications to access the platform resources through standard cryptographic APIs.
- **Protected Storage:** Protected storage in system flash allows secure non-volatile storage of secrets.
- **Physical Protection:** Physical protection is supported by integration of the security hardware in a single device and by packaging the discrete components into a single physical package.

Authentication Products

Unauthorized access has not always been recognized as a security risk especially among private users, even though mobile devices such as PDAs and smartphones are small, portable, and easily lost or stolen. These features lead to a high risk of vital data loss. From this point of view, it is easy to understand the necessity of authentication.

There are several authentication methods (Douglas, 2004, p.13):

- Electronic signature authentication
- Picture-based password authentication
- Fingerprint authentication
- Card-based authentication
- Storage-card-based certificate authentication
- Legacy host access

This section concentrates on products for electronic signature, picture-based password, and fingerprint authentication. A summary of authentication product examples for Pocket PCs and smartphones is presented in Tables A1-A3.

Electronic Signature Authentication Products

Electronic signature authentication has several benefits. It provides a high level of security and an electronic signature is, from the user's point of view, a simple password which cannot be forgotten. The main problem with this kind of technology is that the biographic signature is varying from time to time, which causes the possibility of access denial.

To mention a couple of these kinds of solutions, Romsey Associates Ltd. offers PDALok with dynamic signature recognition and Transaction

Security Inc. has PDA Protect with crypto-sign pattern recognition.

When logging on or synchronizing of data, PDALok forces users to set PIN (personal identification number) or signature. PDALok's biometric technology, dynamic signature recognition, monitors different characteristics of writing as rhythm, speed, pressure, flow, and acceleration. The software is compatible with almost every mobile device running on Window CE and Palm OS (Romsey Associates Ltd., 2005).

Topaz Systems Inc. (2005) provides a more traditional signature authentication alternative. The set with separate writing pads includes software and inkless pen such as SignatureGem. Features of signature authentication products are shown in Table A1.

Picture-Based Password Authentication

Instead of the traditional alpha-numeric login passwords and PINs, Pointsec's PicturePIN and sfr Gesellschaft für Datenverarbeitung mbH's visKey Palm OS picture-based authentication are alternative solutions. Picture-based login style is easier to remember and more user-friendly for mobile devices with small screens and mini keyboards.

Pointsec allows users to select a password consisting of a combination of icons (Figure A1). The position of the Pointsec's icons changes place each time the device is activated (Pointsec Mobile Technologies AB., 2005).

Alternatively, visKey Palm OS users select several desired spots in an image (Figure A2). Before creating the password, visKey Palm OS splits up the selected image into cells. Each cell represents a single character (sfr Gesellschaft für Datenverarbeitung mbH, 2005). The user identifies to the device by choosing the same order of clicks. Features of picture-based password authentication products are shown in Table A2.

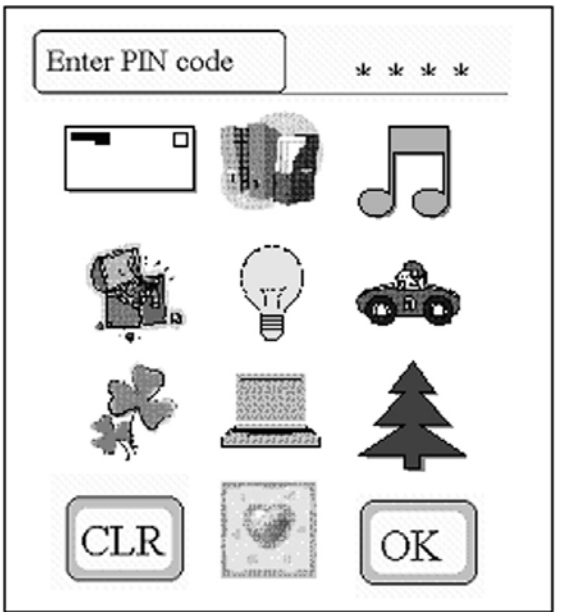
Fingerprint Authentication

Fingerprint-based identification is the oldest method of biometric techniques. The uniqueness of a human fingerprint prevents effectively

Table A1. Signature authentication products

Company	Product Name	Feature / Function
Certicom Corporation	Security Builder	Cross-platform cryptographic module, which allow developers to handle all encryption, decryption, digital signatures and message authentication codes.
Communication Intelligence Corporation	InkTools	Developers' kit with electronic ink capture and display, signature verification, encryption, ink compression and other algorithms.
Romsey Associates Ltd.	PDALok	Uses biometric technology, Dynamic Signature Recognition to prevent unauthorized access to Pocket PC.
Transaction Security Inc.	PDA Protect	Crypto-Sign™ is a biometric pattern recognition technology based upon the submission of a secret sign.
VASCO	Digipass	Digipass offers strong user authentication and electronic signatures.

Figure A1. Pointsec's PicturePIN picture-based authentication



forgery attempts. The security level of fingerprint authentication is depending on such factors as the quality of scanning and the visual image recognition (ROSISTEM, 2005).

Veridt LLC produces fingerprint authentication solutions, for example BioHub for Pocket PC and BioSentry for Compaq iPAQ Pocket PC (Veridt, LLC., 2005). BioHub is a combination of hardware and software for fingerprints authentication. The product contains a plug-in capture device for fingerprint imaging and software which identifies and stores fingerprint patterns.

BioSentry is a separate device into which a Pocket PC is placed. The device compares the fingerprint to the fingerprint minutiaes saved in the Pocket PC's memory. The minutiaes of a fingerprint are defined from a scanned image and the coordinates of these minutiaes are calculated. Finally these coordinates are encrypted and saved. The device uses an encryption algorithm which meets the requirements of AES-128, AES-192, and AES-256 standards. Features of fingerprint authentication products are shown in Table A3.

Encryption Products

One of the simplest methods to protect sensitive data is encryption. Pointsec for Pocket PC provides a solution for real-time encryption of data on both PDAs and different types of memory cards without any user interaction. Data can only be accessed or decrypted with proper authentication (Pointsec Mobile Technologies AB, 2005).

Trust Digital 2005 offers the possibility of full background synchronization of encrypted data (Trust Digital, 2005). Airscanner Mobile Encrypter secures data with optional password methods. Instead of the traditional individual file and folder encryption, where each file can be encrypted/decrypted with its own password, one global password can be applied. After sign-on, transparent and automatic volume encryption takes place within a user-defined time (Airscanner® Corp., 2005). Features of storage encryption products are shown in Table A4.

Anti-Virus Products

Major anti-virus software companies started to develop anti-virus products since the first Symbian OS mobile phone virus, the Cabir worm, was found in 2004 (Kaspersky Lab, 2005).

F-Secure manufactures anti-virus security software, especially for Nokia's mobile phones, for example, Series 60/90 and Nokia 9300/9500 Communicator Series. Symantec offers anti-virus products for Palm OS- and Microsoft Pocket PC-compatible devices. To prevent infection, F-Secure Mobile Anti-Virus and Symantec AntiVirus for Handhelds scan all files automatically and transparently during modification and transference of data, without user intervention. When an infected file is detected, the file is immediately quarantined by the system to protect all other data.

F-Secure Mobile Anti-Virus for Nokia 9300/9500 Communicator Series provides automatic updates for the virus signature database over a secure HTTPS data connection or incrementally with SMS messages.

Figure A2. Gesellschaft für Datenverarbeitung mbH's visKey Palm OS picture-based authentication

Figure A2a

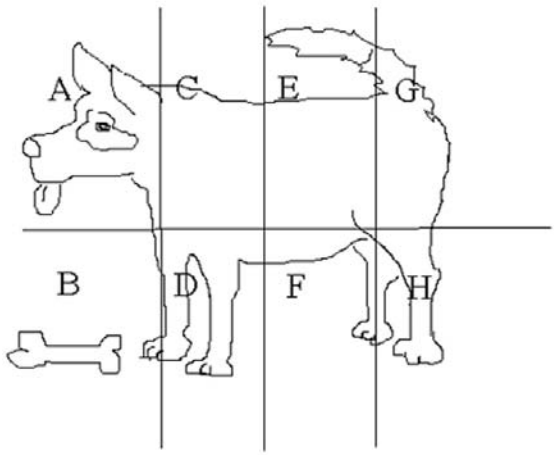


Figure A2b

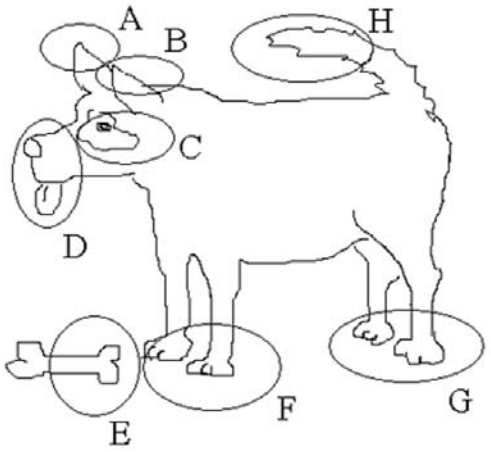

Table A2. Picture-based password authentication

Company	Product Name	Feature / Function
Pointsec Mobile Technologies	Pointsec for Smartphones, Pointsec for Pocket PC, Pointsec for Palm OS, Pointsec for Symbian OS,	The picture-based authentication software enables users to select a password consisting of a combination of icons.
sfr Gesellschaft für Datenverarbeitung mbH	visKey Palm OS	The picture-based authentication software enables users to select several desired spot in an image.
Softava	PicturePassword	User authentication with one click on the desired point of an image.

Table A3. Fingerprint authentication products

Company	Product Name	Feature / Function
Hewlett-Packard Development Company, L.P.	HP iPAQ 5450, 5455 and 5555 Pocket PC.	The HP iPAQ series Pocket PC with inbuilt biometric fingerprint reader.
Veridt, LLC	BioHub	BioHub is a combination of hardware and software for fingerprints authentication solutions.
Veridt, LLC	BioSentry	A fingerprint verification "jacket" for Pocket PC.

Table A4. Storage encryption products

Company	Product Name	Feature / Function
Airscanner Corp.	Airscanner Mobile Encrypter	File and folder encryption for Pocket PC
Asynchrony	PDA Defense	Encrypts all databases, files and memory cards on Pocket PC.
Certicom Corporation	movianCrypt	Encrypts and locks all information without impeding performance or usability on Pocket PC.
Glück & Kanja Group	CryptoEx Pocket	Secure email communication and file storage encryption on Pocket PC.
PC Guardian Technologies, Inc.	PDASecure	Provides data encryption and access control. The software encrypts data based on administrator and user preferences on Pocket PC, Palm OS, smartphone, Symbian and BlackBerry.
Pointsec Mobile Technologies	Pointsec for Pocket PC, Pointsec for Smartphone, Pointsec for Symbian OS	Provides real-time encryption of all data on both their PDAs and all removable media on Pocket PC, smart phone, Symbian OS.
SoftWinter	Sentry 2020 for Pocket PC	Provides encrypted virtual volumes. Data stored on a Sentry volume is transparently encrypted/decrypted.
Cranite Systems, Inc.	WirelessWall	provides FIPS 140-2 certified AES data encryption for Pocket PCs.

With LiveUpdate Wireless feature from Symantec AntiVirus for Handhelds, users are enabled to download virus definitions and Symantec product updates directly to their mobile device with a wireless Internet connection (F-Secure Corporation, 2005; Symantec Corporation, 2005).

Instead of commercial products, BitDefender offers free anti-virus software, BitDefender Antivirus—Free Edition for Windows CE and Palm OS. They are freeware, which means that no license is required for using the products. Features of anti-virus products are shown in Table A5 (BitDefender, 2007).

VPN (Virtual Private Network) and Firewall Products

Wireless networks cause a remarkable security risk because the transmitted data over the air can be easily exploited by outsiders. Secure VPNs use cryptographic tunneling protocols to ensure sender authentication, confidentiality, and integrity of data.

Columbitech's Wireless VPN is a client/server software architecture in which a secure encrypted virtual tunnel between the VPN client (mobile device) and the VPN Server is created to secure the data traffic between the devices. Authentication,

validation, and the transmitted data is encrypted with WTLS (Wireless Transport Layer Security). WTLS is applied because it has better performance than IPSec (IP Security) over wireless networks. Wireless VPN uses the AES algorithm, with up to 256 bit encryption keys.

The software uses PKI (public key infrastructure), smart cards, biometric identification, and one-time passwords as authentication mechanisms. In order to prevent unauthorized access Columbitech's Wireless VPN has firewall functionality on both client and server. The client integrity is ensured with security status monitoring before the VPN tunnel is created. See Figure A3 (Columbitech AB, 2005).

Compared to the more common VPN, that uses IPSec technology, the newer VPN with SSL (secure sockets layer) cryptographic protocol is easier for administrators and users to set up and manage. The benefit of using SSL VPN instead of IPSec VPN is that SSL does not require any client software to be installed on each remote device because SSL is widely supported on most Web browsers (Ferraro, 2003).

Intoto's iGateway SSL-VPN allows users to securely access to key corporate resources at remote locations and create a secure encrypted virtual tunnel through any standard Web browser. iGateway SSL-VPN offers alternative authentication methods: RADIUS (Remote Authentication Dial-In User Service), LDAP (Lightweight Directory Access Protocol), Active Directory, Windows NTLN (NT LAN Manager), and digital certificates (Intoto Inc., 2005).

There are also Linux-based firewalls for PDAs on the market. Firewall programs, such as iptables or netfilter, are included on Familiar's Linux distribution list. Features of VPN and firewall products are shown in Table A6 (The Familiar Project, 2005; Villamil, 2005).

Forensic Analysis Products

While a large variety of forensic analysis software is available for personal computers, the range of solutions is much more limited for mobile devices. The problem is not only fewer software products for PDAs. These products operate only in most common families of PDAs.

The forensic analysis products have three main functionalities: acquisition, examination, and reporting. Only few products have all these mentioned functionalities. In such cases, several software products have to be purchased in order to accomplish the forensic examination process. The forensic analysis products need full access to the devices, in order to start acquisition of data. If the examined device is protected with

Figure A3. Columbitech's Wireless VPN solution

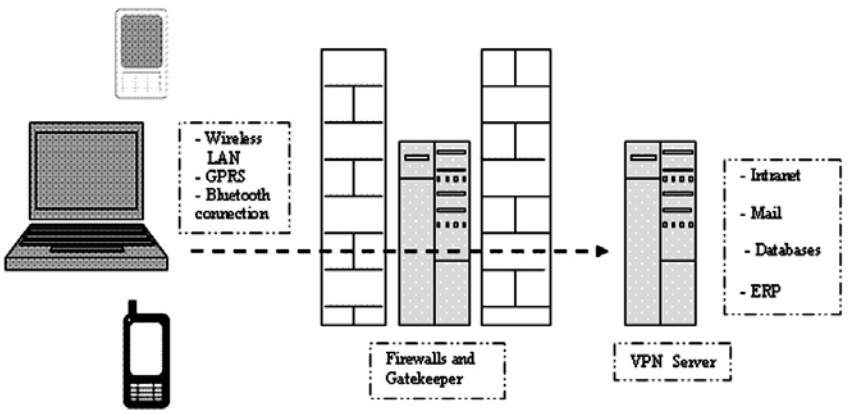

Table A6. VPN and firewall products

Company	Product Name	Feature / Function
Certicom Corporation	MovianVPN	The client for Palm and Pocket PCs operates with VPN gateways from Check Point, Cisco, and Nortel.
Check Point Software Technologies Ltd.	VPN-1 Secure Client	Allow users to securely access resources protected by VPN-1 gateways and provides a personal firewall on Pocket PCs.
Columbitech	Wireless VPN	A client/server software architecture, which create a secure WTLS encrypted virtual tunnel between the VPN client and the VPN Server, to secure the data traffic between the devices.
Ecutel Inc.	Viatores Mobile IP VPN	A client-server VPN solution. The software is based on Mobile IP and IPSec.
Funk Software Inc.	AdmitOne VPN Client for Pocket PC	offers advanced IPsec and IKE technologies to secure the transmission of data between Pocket PCs and the VPN server.
Intoto	iGateway SSL-VPN	enable users to create a secure encrypted virtual tunnel through at any standard web browser. The software offers alternative authentication methods: RADIUS, LDAP, Active Directory, Windows NTLN and digital certificates.
Symbol Technologies Inc.	AirBEAM Safe	A wireless VPN solution for full "end-to-end" security for Pocket PCs. It delivers strong, end-to-end encryption between the corporate firewall and the application server, using industry-standard authentication methodology.
the Familiar Project	Familiar v0.8.2	The firewall program "iptables" is included on Familiar's Linux distribution. Familiar v0.82 supports the iPAQ h series, Siemens Simpad and Sharp Zauri.

Table A7. Forensic analysis products

Company	Product name	Feature
Paraben Corporation	PDA SEIZURE version 3.0.2.43	Forensic acquisition, examination and reporting of data for Palm OS and Pocket PC.
Guidance Software Inc.	ENCASE Version 5	Forensic acquisition, examination and reporting of data for Palm OS.
Symantec Corporation	PDD	Memory imaging and forensic acquisition for Palm OS.
PalmSource Inc.	Palm OS Emulator (POSE)	Forensic examination and reporting for Palm OS.
Compelson Laboratories	MOBILedit!	Forensic gathering and reporting of data for mobile phones.

some authentication method, cracking software is needed.

Paraben's PDA Seizure and Guidance Software Inc's EnCase Forensic Version 5 are forensic analysis tools that allow forensic examiners to acquire, examine, and analyze data. The PDA Seizure tool supports Palm OS, Windows-based OS, and BlackBerry devices, while Encase Forensic currently only supports Palm OS. Both of these mentioned tools have possibility for physical and logical acquisition of data. Physical acquisition means complete bit-by-bit copying of physical storage, for example a disk drive. Logical acquisition also means exact copying of logical storage objects, such as files and folders (Ayers & Jansen, 2004, p.14).

The EnCase Evidence file, created by EnCase, is suitable for the computer security industry and even for the law enforcement. EnCase allows users to determine how or what kind of data will be presented. This depends on the examination purposes. More Forensic analysis products are shown in Table A7 (Guidance Software, Inc., 2005; Paraben Corporation, 2007).

Multi-Functional Products

Multi-functional products are developed to solve comprehensively all security needs of mobile devices. From an administrator's point of view, these kind of products are appealing while there can be saved a lot of resources in terms of effective central administration. In this part of the chapter, three well-known commercial multi-functional solutions from Pointsec Mobile Technologies, PC Guardian Technologies, and Bluefire Security technologies will be presented.

Pointsec has solutions for the following devices and purposes: smartphone, Palm OS, Symbian OS, Pocket PC, and media encryption. PC Guardian Technologies software PDASecure is applicable to the smartphones, Pocket PCs, Palm OS, BlackBerry, and Symbian OS. Bluefire Security Technologies software Bluefire Security Suite 3.5 operates on Palm OS and Windows-based mobile platforms.

One of the most important features of all these multi-functional solutions is the third party management possibility. Administrators can enforce, update, and deploy the company security policy, which is applied also on desktops and laptops. Wished security level is ensured when a user

does not adjust the policy according to their preferences. This means that the security system is user transparent and does not contain or demand any user intervention. Pointsec's software is also compatible with all major third-party management tools, which means that administrators can easily integrate their Pointsec's software into their existing system.

Available third-party management system is used to give remote help such as password reset for users. Bluefire highlights their real-time logging function, which enables the administrator to log and monitor all suspicious activities such as password attempts and changes in firewall security level.

The key function of PDASecure, Bluefire, and Pointsec software is encryption. This feature ensures high security level because all the data can be automatically and immediately encrypted before they are stored or transferred and decrypted automatically by an authenticated user. All of the three example products use the AES (Advanced Encryption Standard) algorithm, the U.S. government approved cryptographic standard with strong 128-bit encryption keys. PDASecure even allows users or administrators to choose from six alternative encryption algorithms.

Authenticated synchronization has been mentioned as an essential part of PDASecure's and Pointsec's mobile device software. Pointsec's ActiveSync system requires the users to authenticate themselves to the mobile device before synchronization with a PC can be started.

None of the example software emphasizes the anti-virus or VPN part of their solution. In this case only Bluefire offers anti-virus and VPN software as an additional feature (Bluefire Security Technologies, 2005; PC GuardianTechnologies, 2005; Check Point Software Technologies LTD., 2007). In Table A8, features of Pointsec, PDASecure, and Bluefire Security Suite 3.5 are shown.

Case Study: Encryption Software Performance Measurements

This case study presents performance measurements on the security software Pointsec for Symbian OS. The purpose was to measure the influence of Pointsec on data communication performance of Symbian OS. Pointsec is presented in more detail in the section, *Add-on Security Software*. According to Pointsec Mobile Technologies, the Pointsec security software should not reduce speed or other performance measures even when the strong 128-bit AES encryption is used to protect the information in the device and in memory cards.

Measurements

However, security solutions may reduce data communication performance measures of mobile operating systems, such as download speed and connection times. These performance measures were measured for a Pointsec security software installation in a Nokia Communicator 9500 for:

- downloading a 4.92 MB file;
- connection to an e-mail server (penti.arcada.fi) with imaps based e-mail client software;
- connection to a www site (www.nokia.com);
- connection to a ssh server (penti.arcada.fi) with a putty ssh client.

All four performance measures were measured six times with and without installed Pointsec security software for two different access network types, WLAN and GPRS. The network bandwidths were 11 Mbit/s for the WLAN and 56 kbit/s for GPRS. Measurement results are presented in Tables A9-A12.

Table A8. Multi-functional products

Features	Company: Pointsec Product: Pointsec for Pocket PC, Smartphone, Symbian OS and PalmOS	Company: PC Guardian Technologies Product: PDASecure	Company: Bluefire Security Technologies Product: Bluefire Mobile Security Suite 3,5
Security policy enforcement from one central location	X	X	X
Remote Help and 3rd party distribution	X	X	X
FIPS 140-2 certified, AES algorithm with 128 bit encryption key	X	X	X
Automatic and immediate encryption	X	X	X
Memory card encryption	X	X	X
Picture-based passwords authentication	X		
Alphanumeric password authentication	X	X	X
Authenticated activeSync	X	X	
Antivirus software / virus protection		X	X
Firewall			X
VPN			X

Usefulness of Measurement Results

Conditions cannot be assumed to be equal for different measurements, since the download speed and connection times were measured for data communication through the public Internet. The utilization of Internet during a measurement session is not deterministic. Measurement results have been considered to be useful if standard deviation is less than 10% of the calculated average for measurements with the same mobile device configuration. Standard deviation exceeded 10% of calculated average only in one measurement case, GPRS connection to an e-mail server without Pointsec security software installed, being about 15% of calculated average (see Table A10).

Measured Degradation of Data

Communication Performance Caused by Pointsec

The influence of Pointsec was considered to be noticeable if the intervals defined by measured average and standard deviation do not overlap with and without Pointsec for otherwise the same mobile device configuration. Noticeable performance degradation was measured only for connection time to a Web site, about twice as long as for a GPRS connection and about 17% longer for a WLAN connection (see Table A11). However, the influence of:

- the traffic load on the Internet, and
- the load on the selected Web server

during carried out performance measurements is unfortunately unknown.

The measurements can thus be considered to support the view of the provider of Pointsec security software, that the performance degradation from this security software is insignificant on a Symbian device.

ABSTRACT

One way of providing technological support for communities of teachers is to help participants to produce, structure and share information. As this information becomes more and more multimedia in nature, the challenge is to build multimedia authoring and publishing tools that meet requirements of the community. In this paper, we analyze these requirements and propose a multimedia authoring model and a generic platform on which specific community-oriented authoring tools can be realized. The main idea is to provide template-based authoring tools while keeping rich composition capabilities and smooth adaptability. It is based on a component-oriented approach integrating homogeneously logical, time and spatial structures. Templates are defined as constraints on these structures.

INTRODUCTION

We are involved in a multidisciplinary project, the aim of which is to support the activities of communities of practice (CoP) in pedagogical environment. This project will provide tools for document production and for document reuse in heterogeneous applications. The objective is to reduce the current limitations caused by the proliferation of data sources deploying a variety

of modalities, information models, and encoding syntaxes. This will enhance applicability and performances of document technologies within pedagogically consistent scenarios. In this paper, we will focus on the authoring needs of teacher communities and propose a new authoring model, LimSee3.

In the educational context, there exists a large variety of authoring tools, see (Brusilowski, 2003) for an extensive review. The main objective of these systems is to provide adaptive educational hypermedia thanks to well-structured hyperlinked content elements that are mostly static content. In Hoffman and Herczeg (2006), the created documents are video centric, providing a way to add timed hot-spot embedding additional media and interaction facilities in the resulting hypervideo. The time structure is, therefore, straightforwardly given by the video media, while the time model of our approach (given by the SMIL time model) is much more general. In our project, we want to provide educators with a way to take advantage of multimedia synchronization to offer more lively pedagogical material. But it is worth noting that multimedia brings a higher order of complexity for authors. In order to reduce this complexity, we propose a multimedia authoring model that will provide similar authoring services than formed-based hypermedia systems (Grigoriadou & Papanikolaou, 2006).

The LimSee3 project aims at defining a document model dedicated to adaptive and evolutive multimedia authoring tools, for different categories of authors and applications, to easily generate documents in standard formats. Our approach is to focus on the logical structure of the document while keeping some semantics of proven technologies such as SMIL (SMIL). This provides better modularity, facilitates the definition of document templates, and improves manipulation and reusability of content. The LimSee3 authoring process is given on Figure 1: a document is created from a template by adding content in an application-guided way. The obtained LimSee3 document can be exported into one or several presentation documents suitable for rendering.

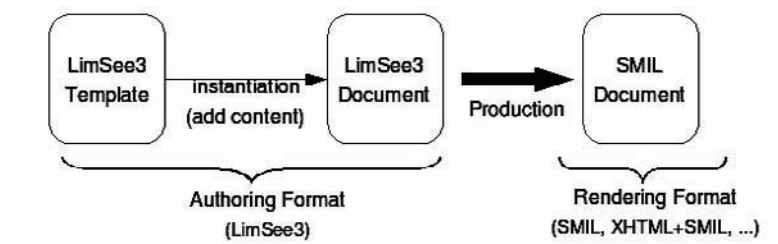
This paper is organized as follows: next section presents a scenario example that will be developed throughout the paper and thereby analyzes CoPs requirements for authoring multimedia documents. We then define the main concepts on which multimedia authoring tools are based, and we classify existing approaches in the light of these concepts. After that, we introduce the LimSee3 document model and show how it can be used for the development of authoring tools tuned for specific CoPs. The last section presents the current state of our development and our perspectives.

A LEARNING-ORIENTED EXAMPLE OF AUTHORING

Multimedia Storytelling for Enhanced Learning

Educators have integrated practice into their curriculum to different degrees; Figure 2 shows this continuum and how LimSee3 can be

Figure 1. The authoring process in LimSee3



naturally used to enhance authoring multimedia documents.

Edward Bilodeau (2003) illustrated that moving towards full immersion requires substantial changes to course design. Careful consideration must be given to the optimal location for student learning to occur on this continuum. Using templates in LimSee3 authoring tool for pedagogical approach allows production process during this continuum. It gives a way of making things simpler and faster to teachers and writers. It focuses on pedagogical issues. It produces practical units of learning (UoL).

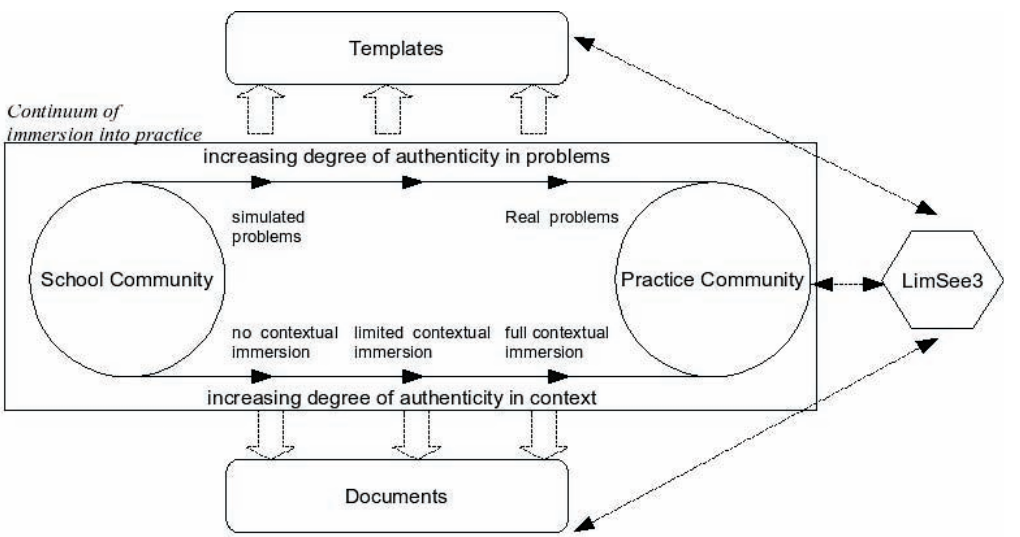
Researchers such as Dolores Durkin (1961), Margaret Clark (1976), Regie Routman (1988; 1991), and Kathy Short (1995) have found evidence that children who are immersed in rich, authentic literary experiences become highly engaged in literature and develop literary awareness. Their studies revealed that positive and meaningful experiences with books and written language play a critical role in the development of literacy skills. Other researchers have found that students acquired reading and thinking strategies in literature-based programs that included teacher-led comprehension instruction (Baumann, 1997; Block, 1993; Goldenberg, 1992/1993).

Storytelling in the Learning Process

Stories are basic: we start telling our children about the world by telling them stories. Stories are memorable: their narrative structure and sequence makes them easy to remember. "What happens next?" is a very basic form of interest and engagement. Stories are everywhere: very rarely in real life do we set out to convey ideas in terms of hierarchies or taxonomies or bullet points. Instead, we tell stories. Teaching is one of the predominantly professional activities that do habitually communicate by means of stories, and also use elaborated language codes.

We want to go deeper inside the multimedia process, taking into account the advantage of creating multimedia in the immersion process. As an example, U-Create (Sauer, Osswald, Wielemans, & Stifter, 2006) is an authoring tool centered on 2-D and 3-D scenes targeted to nonprogrammers who want to easily produce story documents. The tool is based on predefined structural elements

Figure 2. Continuum of immersion into practice (Adopted from Hogan, 2002) and LimSee3 use



(from story, scene, to action, stageSet, and asset) and associated dedicated GUIs.

In this paper we consider a group of teachers that are working together—a CoP in our terminology—to create and share course materials based on tale storytelling.

TALE LEARNING EXAMPLE

Little Red Riding Hood Example

Little Red Riding Hood is a well-known and well-loved fairytale dating back to over 3 centuries ago when it was first published by Charles Perrault in his Histoires ou Contes du temps passé in 1697 and based on oral European tales. Since then, Little Red Riding Hood has been retold in a variety of forms and styles, as Big Books and Lift-the-flap books, as poems and plays, and whilst some details may have changed, many of the essential elements have stayed the same. Little Red Riding Hood makes a great literature teaching unit theme for elementary school.

A general synopsis follows:

Act I.1

Setting at the edge of a forest; the Little Red Riding Hood goes off to take a basket to her ill grandmother, her mother warns her not to dawdle in the woods or to talk to strangers.

Act I.2

A place inside the forest. Woodcutters can be heard chopping wood. Little Red Riding Hood comes out of some bushes. As she pauses to pick some flowers, the wolf catches sight of her. On the path he stops her and makes up a story about a shortcut to grandmother's house. When he challenges her to see who will get there first, she agrees, and both of them run off in different directions as the woodcutters resume their work.

Act II.1

The chorus explains that the wolf has not eaten for 3 days and was able to get to grandmother's house first. The wolf, pretending to be Little Red Riding Hood, manages to get into the house and swallow grandmother. He takes her place in the bed before Little Red Riding Hood arrives. In several questions she expresses her surprise at how differently grandmother looks now, and the wolf swallows her.

Act II.2

Some hunters and woodcutters, who have been tracking the wolf, come by and enter the house. They find the wolf asleep and open his belly to let grandmother and Little Red Riding Hood out. After they sew up the wolf again, he repents and is permitted to live in the forest as long as he lives up to his promise to be good.

In the learning process, it is possible to exploit this story in different approaches (Franc-parler. org, 2006), for instance:

Story and the time: a) After reading the tale and giving explanations of difficult points and incomprehensions, to work on the chronology from drawings. b) Try and feel the knowledge of the terms "before," "later," during this time line.

Oral expression: a) Drawing images and explaining them. b) Playing dialogues without written support. c) Reciting a rhyme or poem, singing a song.

A variety of resources, ranging from texts, illustrations, media presentations to computer-based interactive materials for students are available for use in classroom. Based on these materials, a teacher can propose:

- **Story:** Tell the story, watch and comment movies
- **Songs:** Organize some spoken drill type activities
- **Handcraft activities:** Propose drawing, folding, coloring of sceneries, puppets, and so forth

- **Play:** Study and put on stage a personalized version of the story

Basically, the units of learning that are exchanged in this CoP of teachers are multimedia story documents that are composed of sequences of story steps where data elements are heterogeneous and multimedia. The challenges are to enrich information with the synchronization of data elements (for instance an activity with the corresponding material) and to provide a document structure enabling knowledge sharing and reusability (of stories).

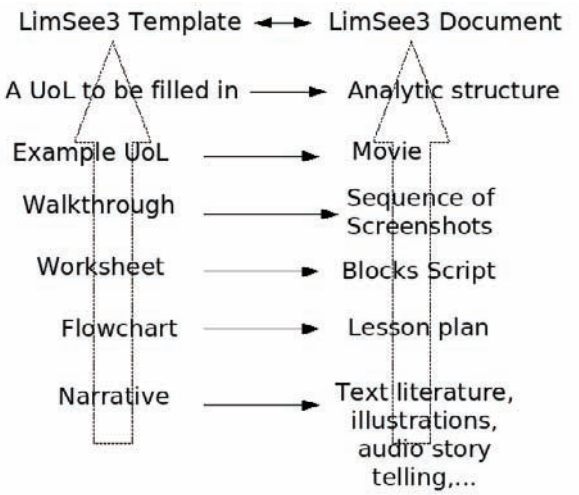
The CoP of teachers needs templates for making things simpler, faster, for being focused on pedagogical issues, for producing practical units of learning. The Fig. 3 shows the structural link between LimSee3 Template and LimSee3 document contents. At the lower level, a narrative part inside the template corresponds to text literature and/or illustration and/or audio storytelling. At a higher level, a template walkthrough corresponds to a sequence of screenshots. The first level is offered by the BNF (BNF, 2001) that, for instance, gives out textual contents and illustrations. To fully instantiate upper levels, we show a possible making of the tale with a logic modeling [template and document] from which we can extract levels to enhance associated authoring.

From the continuum of immersion into practice, represented inside the rectangle of the Fig. 2, we learn that the greater the degree of authenticity of the learning activities, the more the students will be able to be integrated into the practice. Different programs and courses benefit from different levels of immersion. Moving towards full immersion requires substantial changes to course design. Teachers need authoring tools to set up these types of pedagogical materials. Careful consideration must be given to the optimal location for student learning to occur in this continuum. In this CoP, a number of teachers will create templates to build this type of very specialized tools. Such a modeling will naturally emerge from CoP work, using LimSee3 inside this continuum (see Fig. 2).

Basic Requirements for CoP-Oriented Learning

In order to be useful, the cooperative services to be provided to the CoPs must have the two following basic features: (i) authoring tool of stories dedicated to teachers; (ii) access tool

Figure 3. LimSee3 template and document links



to read the existing stories. Looking more closely at the ways in which CoPs participants are producing multimedia information, we can identify some requirements for the authoring and presentation platform:

1. Simple and efficient authoring paradigms—because CoPs members are not (always) computer science technicians.
2. Easy and rapid handling of the authoring tool—because new members can join CoPs.
3. Modular and reusable content—because multimedia information results in a coconstruction process between members.
4. Evolutive structuring of documents —because of the dynamic nature of CoPs objectives.
5. Use of standard formats—because CoPs need portability, easy publishing process, and platform independence.

Basically, our approach proposes a template mechanism to cope with requirements 1 and 2, a component-based structuring enabling requirements 3 and 4, and relies on proven standard technologies to ensure the last requirement. Before further stating our authoring model, we present in the next section the main concepts and approaches of multimedia authoring on which this work is based.

MULTIMEDIA DOCUMENTS AND MULTIMEDIA AUTHORING

In traditional text-oriented document systems, the communication mode is characterized by the spatial nature of information layout and the eye's ability to actively browse parts of the display. The reader is active while the rendering itself is passive. This active-passive role is reversed in audio-video communications: active information flows to a passive listener or viewer. As multimedia documents combine time, space, and interactivity, the reader is both active and passive. Such documents contain different types of elements such as video, audio, still-picture, text, synthesized image, and so on, some of which have intrinsic duration. Time schedule is also defined by a time structure synchronizing these media elements. Interactivity is provided through hypermedia links that can be used to navigate inside the same document and/or between different documents.

Due to this time dimension, building an authoring tool is a challenging task because the WYSIWYG paradigm, used for classical documents, is not relevant anymore: it is not possible to specify a dynamic behavior and to immediately see its result. Within the past years, numerous researchers have presented various ways of authoring multimedia scenarios, focusing on the understanding and the expressive power of synchronization between media components: approaches can be classified in absolute-based (Adobe, 2004), constraint-based (Buchanan & Zellweger, 1993; Jourdan et al., 1998), event-based (Sénac, Diaz, Léger, & de Saqui-Sannes, 1996) and hierarchical models (SMIL), (Van Rossum, Jansen, Mullender, & Bulterman, 1993). Besides, to cope with the inherent complexity of this kind of authoring, several tools (Adobe, 2004), (Microsoft, n.d.), (Hua, Wang, & Li, 2005) have proposed limited but quite simple solutions for the same objective. Dedicated authoring, template-based authoring, and reduced synchronization features are the main techniques to provide reasonable editing facilities. But we can notice that these tools generally also provide scripting facilities to enrich the authoring capabilities and therefore, lose in some way their easiness.

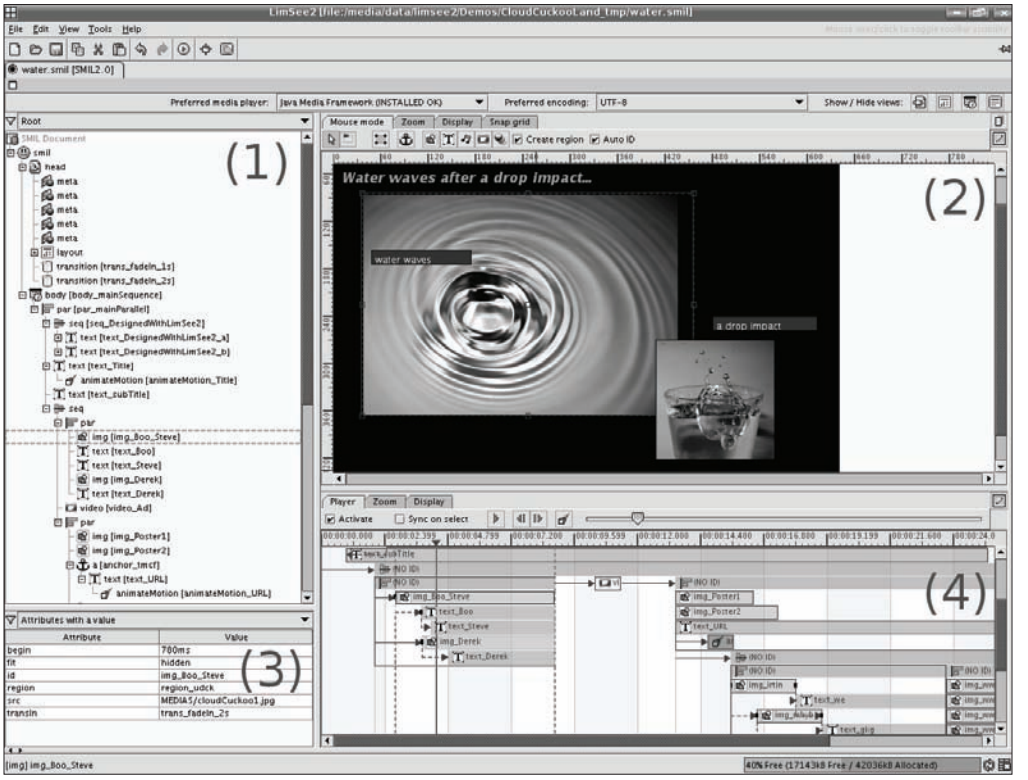
Beside timelines, script languages, and templates, intermediate approaches have been proposed through "direct manipulation" and multiviews interface paradigms. IBM XMT authoring tool (IBM) and SMIL tools such as LimSee2 (LimSee2) and Grins (Oratrix GRiNS) are good examples. In LimSee2, the time structure of SMIL is represented for instance in a hierarchical

timeline as shown in of Fig. 2 (4). Time bars can be moved or resized to finely author the timing scenario. This kind of manipulation has proven very useful to manipulate efficiently the complex structures representing time in multimedia XML documents.

However, even if XMT and SMIL are well-established languages, these tools are too complex for most users because they require a deep understanding of the semantics of the language (e.g., the SMIL timing model). Moreover, these models generally put the time structure at the heart of the document, whereas it does not always reflect exactly the logical structure in the way it is considered by the author. Our approach instead sets this logical dimension as the master structure of the document, which is a tree of modular components, each one specifying its own time and spatial structures. Additionally, the document can be constrained by a dedicated template mechanism.

A template document is a kind of reusable document skeleton that provides a starting point to create document instances. Domain-specific template systems are a user-friendly authoring solution but require hardly extensible dedicated transformation process to output the rendering format. We chose, on the contrary, to tightly integrate the template syntax in the document: the template is itself a document constrained by schema-like syntax. The continuum between both template and document permits to edit templates as any other document, within the same environment, and enables an evolutive authoring of document instances under the control of templates. There is no need to define a dedicated language to adapt to each different use case.

Figure 4. Multiview authoring in LimSee2



We believe that the combination of document structuring and template definition will considerably help CoPs in (i) reusability of materials, (ii) optimization of the composition and life cycle of documents, (iii) development and transmission of knowledge, (iv) drawing global communities together effectively.

THE LIMSEE3 AUTHORING LANGUAGE

Main Features

In the LimSee3 project, we define a structured authoring language independently of any publication language. Elements of the master structure are components that represent semantically significant objects. For instance, a folktale can be seen as a sequence of scenes. Each step is composed of several media objects and describes a phase of the story (departure from home, encountering the wolf,...). Components can be authored independently, integrated in the document structure, extracted for reusability, constrained by templates, or referenced by other components.

The different components of a multimedia document are often tightly related with one another: when they are synchronized or aligned in space, when one contains an interactive link to another, and so on. Our approach, which is close to the one proposed in Silva, Rodrigues, Soares, and Muchaluat Saade (2004), is for each component to abstract its dependencies to external components by giving them symbolic names. This abstraction layer facilitates the extraction of a component from its context; thus, enhancing modularity and reusability.

Finally, the goal is to rely on existing proven technologies, in both contexts of authoring environments and multimedia representation. The timing and positioning models are wholly taken from SMIL. Using XML (XML, 2006) provides excellent structuring properties and enables the use of many related technologies. Among them are XPath (Xpath, 1999), used to provide fine-grained access to components, and XSLT (XSLT, 1999), used in templates for structural transformation and content generation.

The authoring language is twofold: it consists in a generic document model for the representation of multimedia documents, and it defines a dedicated syntax to represent templates for these documents.

In this section, we describe the main features of the LimSee3 language and we illustrate their syntax with short excerpts of the storytelling example.

Document Model

A *document* is no more than a document element wrapping the root of the object hierarchy and a head element containing metadata. This greatly facilitates the insertion of the content of a document in a tree of objects, or the extraction of a document from a subtree of objects.

A compound object is a tree structure composed of nested objects. Each compound object is defined by the object element with the type attribute set to compound. It contains a children element that lists child objects, a timing element that describes its timing scenario, a layout element that describes its spatial layout, and a related element that abstracts out dependencies to external objects.

The value of the localId attribute uniquely identifies the component in the scope of its parent object; thereby also implicitly defining a global identifier id when associated with the localId of the ancestors. In Example 1, the first child of object scene1 has the local id title and hence is globally identified as scene1.title.

The timing model, and similarly the positioning model, is taken from SMIL 2.1. The timing element defines an SMIL time container. The timing scenario of a component is obtained by composition of the timed inclusions defined by

the timeRef elements, whose refId attributes are set to local ids of children.

A *media object* is actually a simple object that wraps a media asset, i.e. an external resource (such as an image, a video, an audio track, a text...) referenced by its URI. It is defined by the object element with the type attribute set to either text, image, audio, video, or animation. The URI of the wrapped media asset is put into the src attribute. Example 2 shows an image media

Figure 5. Example 1 - A simple scene LimSee3 document

```
<document xmlns="http://limsee3.gforge.inria.fr/ns"
  xmlns:template=".../ns/template"
  xmlns:smil="http://www.w3.org/2005/SMIL21/">
  <head><!-- some metadata --></head>
  <object localId="scene1" type="compound">
    <children>
      <object type="text" localId="title">
        ...
      </object>
      <object type="image" localId="illustration1">
        ...
      </object>
      ...
      <object type="compound"
        localId="navigation-bar">
        ...
      </object>
    </children>
    <timing>
      <smil:par dur="30min">
        <timingRef refId="title" />
        <timingRef refId="illustration1" />
        ...
        <timingRef refId="navigation-bar" />
      </smil:par>
    </timing>
    <layout height="600" width="800" />
  </object>
</document>
```

Figure 6. Example 2 - A LimSee3 object with an external dependency relation

```
<object localId="right-button" type="image"
  src="./medias/right-arrow.png">
  <related>
    <ref localId="target" refId="story.scene2"/>
  </related>
  <children>
    <object type="area" localId="link">
      <attribute name="src">#<value-of
        refName="target" select="@id" />
    </object>
  </children>
  ...
</object>
```

object with local id right-button that wraps the media asset identified by the relative URI ./medias/right-arrow.png.

Area objects inspired from the SMIL area element can be associated to media objects. They are used for instance to structure the content of a media object or to add a timed link to a media object. An area is defined as an object element with the type attribute set to area. For instance, in Example 2 the media object right-button has a child area, which defines a hyperlink.

Relations of dependency between objects are described independently of their semantics in the document. External dependencies are declared with ref elements grouped inside the related child element of objects. The value of refId of a ref element is the id of the related element, and the value of localId is a symbolic name that is used within the object to refer to the related object. For instance, in Example 2, object right-button provides a clickable image that links to the object story.scene2 by first declaring the relation in a ref element and then using this external object locally named target to set the value of the src attribute of the link, using attribute and value-of elements taken form XSLT.

Templates

Template nodes aim at guiding and constraining the edition of the document. In order to have better control and easy GUI setup, the language includes two kinds of template nodes: media placeholders and repeatable structures.

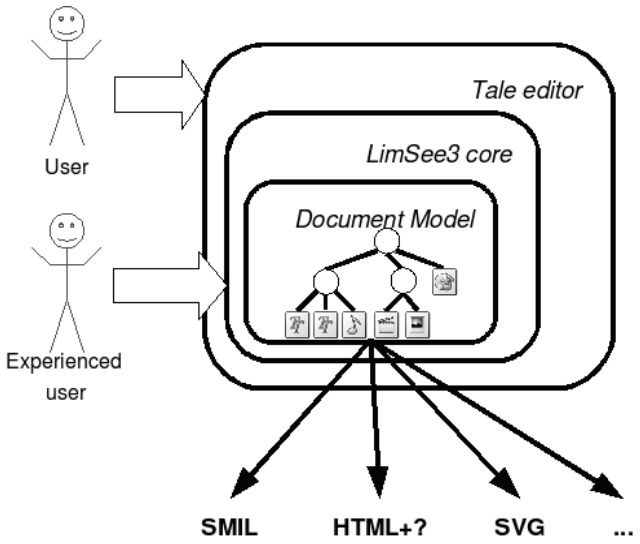
A *placeholder* is a template node that defines a reserved place for a media object. It is represented by an object element, whose type and src attributes are not (yet) set. It specifies the kind of media resources it accepts in a special template:types attribute (the values can be text, img, audio, video, animation, or a list of these types). The author can also specify content that will be displayed to invite the user to edit the media zone with the template:invite element (of any media type). For instance, Example 3 shows a media placeholder title for a text, with textual invitation. During the authoring process, placeholders are filled with media objects inserted by the user.

A *repeatable structure*, represented by the template:model element, is a possibly complex template node that defines a homogeneous list of objects. Each item of the list matches the model. The cardinality of the list can be specified with the min and max attributes. Example 3 shows a tale

Figure 7. Example 3 - A scene template

```
<template:model name="tale-scene" min="1">
  <object>
    <children>
      <object localId="title" template:types="text">
        <children>
          <template:invite type="text">Fill in the title of this scene</template:invite>
        </children>
      </object>
      <template:model name="illustrations" min="1" max="5">
        ...
      </template:model>
      <object localId="questions" template:types="text">...</object>
      <object localId="navigation" type="complex">...</object>
    </children>
    <timing>...</timing>
    <layout>...</layout>
  </object>
</template:model>
```

Figure 8. The LimSee3 three-layer architecture



scene template named tale-scene: this complex model is composed of several placeholders (title, questions), an embedded model (illustrations), and the navigation object.

Finally, our model makes it is possible to lock out parts of a document with the locked attribute, to prevent authors from editing these parts. This allows for instance to guide more strongly inexperienced users by restricting their access to the only parts of the document that make sense to them.

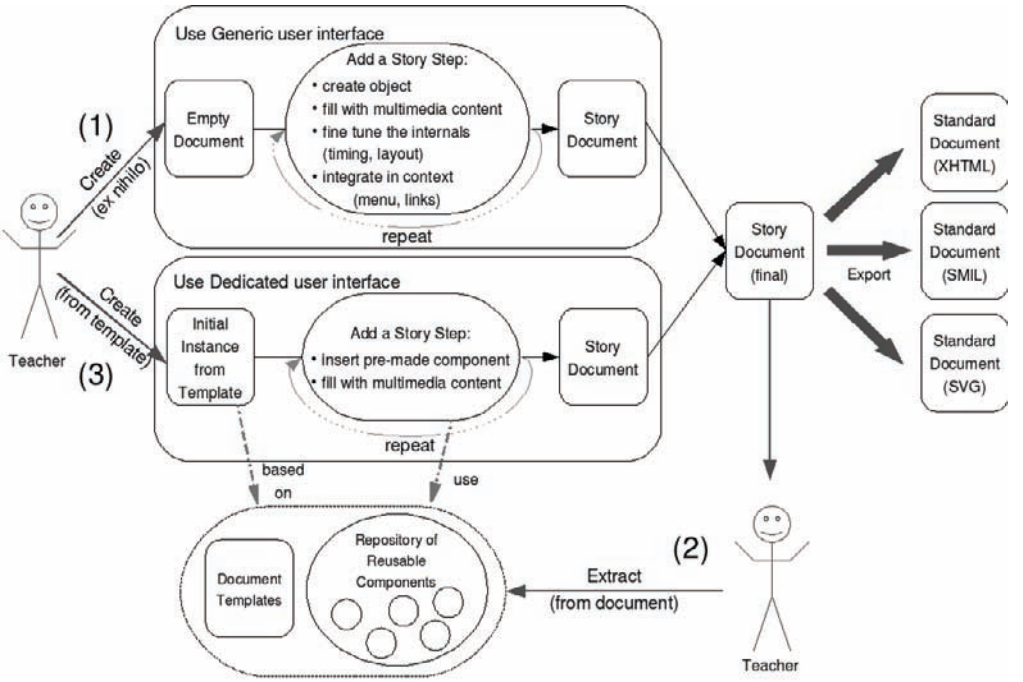
AUTHORING WITH LIMSEE3

The LimSee3 model defined in the previous section aims at being an internal kernel of our authoring system as can be seen on Figure 8. This model is hidden from the user by several abstraction layers: experienced users interact with a full-featured generic platform (LimSee3 core) that enables them to finely tune all document properties, however, at the cost of some technical overhead, while basic users interact with template-specific simplified interfaces that allow them to author documents with less effort. In the case of a teacher's CoP that wants to create and share multimedia materials for tale telling, the benefits that could be achieved with LimSee3 are the following:

- **To describe the author's vocabulary** by structuring basic medias into author-defined logical multimedia structures ("tale scenes" viewed as collections of "illustrations" and "narrations," rather than mere "pictures" and "texts")
- **To adopt the author's vocabulary in the authoring process** by leveraging the logical coherence between the document to produce and the way to produce it (the template structure reflects the logics of the presentation, not its technical needs)
- **To facilitate document reuse in the CoP** by easily extracting, adapting, merging documents, applying alternate layouts for different pedagogical purposes

Figure 9 shows the different steps of the production of tale tellings by the member of teachers CoP. First, an experienced author creates a tale story from scratch using the LimSee3 core plat-

Figure 9. Authoring with LimSee3



form (flow (1) in the Figure 9) in order to define the logical structure of this pedagogical material that will allow a fruitful use in classroom. Eventually this multimedia tale will be refined thanks to inputs from other teachers of the CoP. When a consensus is reached, this teacher can use the LimSee3 core to extract a template document from this instance (flow (2) in the Figure 9). The main structure of the document, in this case a sequence of scenes, can be constrained by template nodes such as repeatable structures. The result of this step will be a dedicated authoring interface that other teachers can use (flow (3) in the Figure 9) to create new multimedia tale stories. This is a typical example of participative design leading to the development of a dedicated tool based on the LimSee3 generic platform.

The Figures 10 and 11 illustrate this last step of authoring with a dedicated GUI:

- Figure 10 shows how the placeholders defined in the template structure can lead to simple drag-and-drop authoring actions.
- Figure 11 illustrates the advantages gained with the separation of logical, spatial, and time information. It allows the authoring and rendition of several scenarios of the same content: thanks to a direct manipulation in the timeline view, an author has defined a sequential display of the illustrations instead of the default parallel one.

Finally, the proposed application can evolve to take into account new needs of the CoP members. For instance, a teacher wants to register his/her course, using a camera that films her/him while (s)he gives a talk illustrated with the multimedia tale document. In order to easily synchronize the video with the different parts of the tale document, the authoring tool is enriched with a simple control panel, as can be seen on the left part of Figure 12.

Figure 10. Instantiating a template document by drag-and-drop

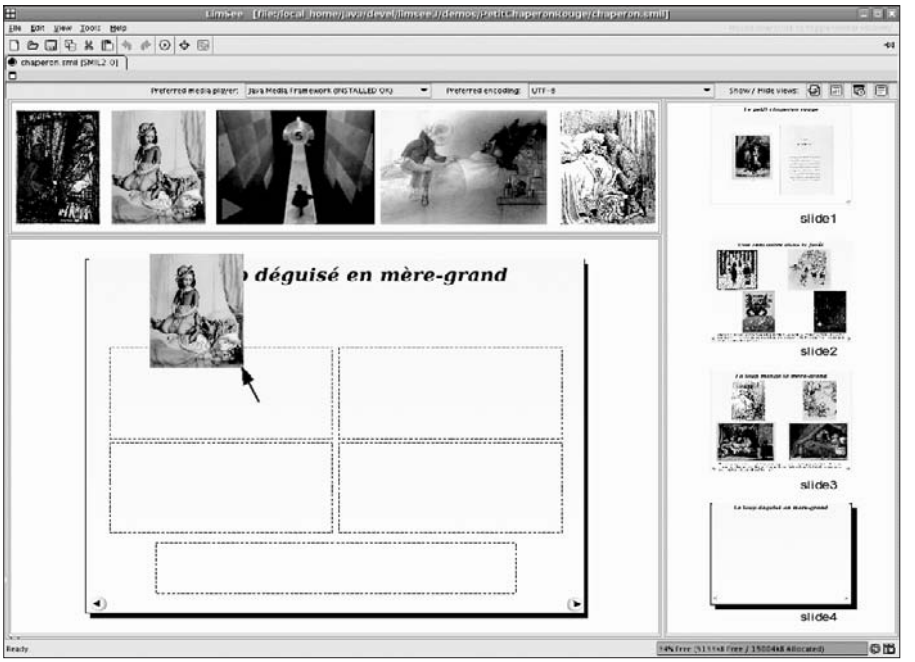


Figure 11. Modifying the timeline

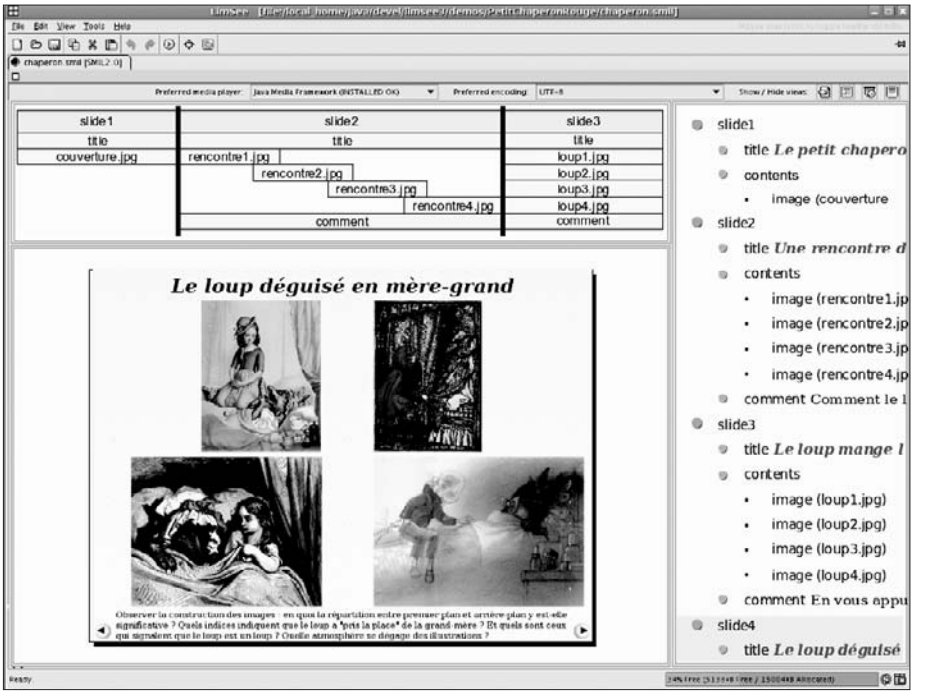

Figure 12. Synchronizing a video with a story document

CONCLUSION

The LimSee3 model leads to the development of authoring tools that fit the requirements stated at the beginning of the paper. The LimSee3 core is currently under development as a cross-platform open-source Java software: we provide this generic platform with widgets to manipulate all the elements defined in the model (documents, compound objects, timing and layout details, relations...). It provides features based on the proven authoring paradigms such as multiviews, timeline, structure tree, and 2-D canvas.

The model presented in this paper develops a practice-based approach to multimedia authoring dedicated to communities where collaborative and participative design is of high importance. It improves reusability with template definitions and with the homogeneous structuring of documents. In the context of Palette, we will use this model to develop dedicated authoring tools for pedagogical CoPs.

Chapter 3.10
Screenspace

Kevin H. Jones
University of Oregon, USA

ABSTRACT

From tiny interactive cellphone screens (keitai) to supersized jumbo LED displays, Tokyo's urban landscape is changing drastically. A corner that once displayed billboards that occasionally flipped has now become lit-up and is in constant motion. Keitai, with their built-in cameras, now allow images to be sent from one to another and have become essential to urban life. As these screens become architectural and fashion statements, Tokyo's nomadic high-tech culture is commuting even greater distances, living in more compact housing, and allowing for "cellspace" and "screenspace" to merge.

Today we live in the imaginary world of the screen, of the interface…and networks. All our machines are screens, we too have become screens, and the interactivity of men has become the interactivity of screens.

–Jean Baudrillard

INTRODUCTION

Since the mid-1970s, with the development of the personal computer, interactive screens have slowly become part of our daily lives. The first interactive screens introduced were monochromatic, very much text-driven, and still referred to the structure of the printed page. Rudimentary images had to be cleverly created with the characters presented on the computer's keyboard.

Today, we find ourselves surrounded by vast wireless networks that we interface with through the use of electronic devices ranging from simple text messaging to high-resolution graphics on laptop computers. Various sized screens with rich GUI's (graphical user interface) are portals that allow us to interact with software on these devices. This invisible electromagnetic, hertzian space[1] has been growing rapidly since the mid-20th century. Urban landscapes are not only changing because of the mobility and interactivity of these screens, but also because of the proliferation of large-screen LED displays that are at every corner vying for our attention.

From Times Square in New York City to Shibuya Crossing in Tokyo, urban space is changing drastically. A corner that once displayed billboards that occasionally flipped has now become lit up and is in constant motion. Even though these screens are neither mobile nor interactive, the graphics that are displayed upon their surfaces light up the streets and mirror the motion of the city.

With this chapter, I will be looking at the proliferation of screens found in Tokyo and how they have transformed public and personal space. I will look closely at the "keitai"[2] with its tiny screens that dot Tokyo's landscape, all the way up to the "supersized" LED displays found in major entertainment and shopping areas in Tokyo. I will examine various screens' mobility, interactivity, social effects, and how graphics and typography are displayed on these devices.

CELLSPACE

Tokyo is a city in flux; it is in constant motion. With the daily influx of millions of commuters all with "keitai", cellspace is a dominant structure upon its urban fabric. The term "cellspace" was first coined by David S. Bennahum while using his Palm Pilot with a wireless modem to access the web and send e-mail while waiting for a NYC subway train in 1998. Cellspace surrounds us with its tangible and virtual interfaces, as well as the invisible wireless network that it has created. Today, it is everywhere and is a communication space for the nomad, allowing unparalleled movement and convenience.

Japan is a country with limited space, and Tokyo is one of the most crowded and expensive cities in the world. With high rents and one -third of living spaces averaging 400 square feet, urban apartments average approximately one room in size. Space is at a premium. Because of this lack of affordable and large housing in Tokyo, many Japanese commute up to four hours round trip from their homes in the surrounding suburbs to their places of employment. This distance from their offices makes for a very long commute on Tokyo's extensive rail system—perfect for the use of the popular keitai.

During my first residence in Japan in 1998, my daily one-way commute was one hour and 30 minutes from my front door to the Musashanita train station, then a train to the Megro station where I changed to the JR Yamanote line, which brought me to the Shinjuku train station, where again, I switched to another train that took me to the Hatsudai train station. After a 10-minute walk from there, I would finally arrive at the front door of the graphic design studio where I worked. I quickly discovered that this commute is not unusual for the Tokyo worker, as I was commuting with millions of others five days a week. During my daily commute, I would often read, just as all of the other passengers did to pass the time away and to avoid eye contact. But this has now changed: the majority of passengers are not reading the static text of a book or newspaper, but clicking away with their thumbs at their keitai keys. These commuters are not talking, (that would be impolite), but writing e-mails and entering into their individual cellspace.

The keitai that the Japanese use are extremely sophisticated: all current models are able to send and receive e-mail and have access to a limited amount of official webpages (with a subscription to one of the most popular service providers: I-mode or J-sky). Along with access to an already familiar interface, many phones allow low to medium resolution images to be captured with the keitai built-in camera and sent to another keitai or computer. Called sha-mail[3], these camera-enabled keitai have become extremely popular. Their screens allow thousands of colors of resolution and have built in 3D polygon engines. Streaming video from one keitai to another is on the horizon. With the rapid development of technologies related to the keitai, one can only imagine what the next generation will bring. How wonderful would it

be to conduct a videoconference with my associates at Sony as I finish my cup of coffee at the local coffee shop. Or, even better, play network games, watch bootlegged movies, or use it as a spy-camera. What this next generation of keitai will present is not only a hyper-cellspace: it will add to what I will refer to as screenspace.

SCREENSPACE

Tokyo is a city of not only cellspace, but of screenspace. Electronic displays are everywhere, from the tiny keitai screens to the monolithic LED screens found on the buildings in Shibuya, Shinjuku, and other major entertainment areas. The largest concentration of these large-scale displays can be found in Shibuya, a popular shopping district in Tokyo. Standing outside of the Shibuya JR (Japan Railroad) train station waiting to cross a busy intersection, one is assaulted by a total, at last count, of three large LED displays[4], one at least six stories tall and meshed into a building. All attempt to gain your attention. Here, screens become architecture, screens overtake the physical space, dwarf pedestrians, and launch you into screenspace.

All at once, you find yourself surrounded by things in motion, people with and without keitai, automobiles, images, and type. This experience of screenspace is one that is on a grand scale, but there are countless other examples of screenspace to be experienced in Tokyo. JR Trains now have large hi-definition screens throughout the cars updating us on the weather forecast, news, and latest canned coffee drink as we commute. Plasma screens are also all the rage in Tokyo; having one mounted—hung like a painting—in your apartment makes any image on it a work of art.

Also on the streets of Tokyo, one finds the flickering video arcade. Inside, there is the martial-arts superhero game with its familiar joystick controller along with games having much more developed physical interfaces. One involves a dance floor where users interact with a virtual character and try to keep up with dance beats. Another requires a user to beat on taiko drums as digital images on a screen key you when to do so. These hyper-interactive tangible interfaces mesh screenspace to a physical presence. Like the keitai

Figure 1.

with its individual interaction, these video games are changing the physical and virtual landscape of contemporary Tokyo.

As the video arcades in Tokyo exhibit tangible interfaces fused with screens, the even more common Pachinko parlors now have small-embedded LCDs. The Pachinko parlor itself is a spectacle. Upon entering, the sound of thousands of cascading silver balls all at the control of gravity release a pulsating wave of metal. These machines also play computerized jingles. With the addition of movement from computer graphics on the built-in LCD screens and the drive to gamble, an electrifying effect is created.

As the physical world meshes with the virtual in Tokyo, the screens are friendly and unintimidating. For example, at the JR Shinjuku station, I interface with the ticket machine through its extremely clear GUI as I choose my fare. A 180-yen ticket is presented, a virtual ticket agent bows with a "thank you," and I am on my way. Throughout Tokyo, this interaction with various electronic devices and their screens is polite, apologetic, and clear. Warning beeps or alarms tend to be pleasant and instructive, rather than loud and embarrassing. Cute characters along with strategically placed blinking LEDs explain instructions and directions. It seems that the Japanese are at a much greater ease with technology and its integration into daily life.

This acceptance of technology into daily life in Japan permits screenspace to exist. Major electronic companies such as Sony, Panasonic and Hitachi, to name a few, all release their products for consumer testing on the streets of the Akihabara district in Tokyo. Akihabara—"electric city" in Japanese—is very befitting. On its streets, one finds everything from the latest electronic goods to the raw components that make up these high-tech devices. Here in this bazaar of capacitors, transistors, and micro-controllers, various screens can be found—from simple LED displays to compact high-resolution screens. These raw components found in Akihabara fuel the ingenuity and creativity of Japanese electrical engineers, designers, and artist.

With all of these screens in Tokyo, the keitai, with its mobility and personal space, is the most powerful. The mobility that the keitai exhibits is drastically changing daily life in contemporary Japan and can be compared to some of Tokyo's compact architecture. The keitai is small, functional,

Figure 2.

and mobile. It is necessary for anyone traversing Tokyo's urban landscape. (In fact during my last visit, I found myself feeling awkward having to use the vulnerable payphone.) The ubiquitous capsule hotel also exhibits the same characteristics: functional and necessary in contemporary Tokyo. Positioned near major intersections of travel and entertainment, the capsule hotel allows the businessman[5] who has missed the last train home a sleeping birth one meter by one meter by two meters, sleek yet brutally functional. This functionality and compactness to support all forms of mobility is exemplified in Kisho Kurakabo's Nakagin Capsule Tower found in Ginza. Built in 1970, its 74 capsules are all equipped with a single bed, unit-bath, and entertainment center, initially intended to be purchased by companies to allow temporary stay for the mobile businessman. This compactness and mobility that the Japanese have become accustomed to is essential to the keitai popularity. With the amount of commuting and time spent away from home, the keitai presents itself as a necessary interface for contemporary Japan.

Figure 3.

DIGITAL TYPOGRAPHY: AESTHETIC OF THE PIXEL

With the multitude of screens found in Tokyo, viewing graphics or reading their type can be tiring on the eyes. Type, in particular, can be troublesome: it is often in Japanese and in a vertical format. All images and characters must adhere to various screen resolutions creating, at times, very coarse graphics and jagged type.

On the keitai, one will often find Hiragana, Katakana, and Kanji[6] with little English. Much typography on the keitai is comparable to type on an early Macintosh SE. It is typically black on white, static, and read in the body of an e-mail or a simple interface. It is meant to be personal and clear. This treatment aligns itself with the printed page and Tschichold's New Typography: simple, clear, and clean. But upon closer look, the type is coarse and blocky, adhering to the screen's matrix of pixels.

This coarse and blocky type is not new to typography. Wim Crouwel's 1966 Vomgevers poster for the Stedelijk Museum in Amsterdam used a typeface that adheres to a rigorous grid. Called Stedelijk, this typeface has a very similar look to many "pixel fonts" that are being designed for screens today. Later, in 1967, Crouwel designed New (Neue) Alphabet, a result of his using the first electronic typesetting machines. New Alphabet was a radical design: it removed all diagonal strokes and curves in its individual characters. New Alphabet reduced characters to their essential elements, creating a font that is strictly vertical and horizontal, again adhering to the grid.

More recently, in 1985, Émigré released the Oakland typeface. Designed by Zuzana Licko, it is a coarse bit-mapped family that was a response

Figure 4.

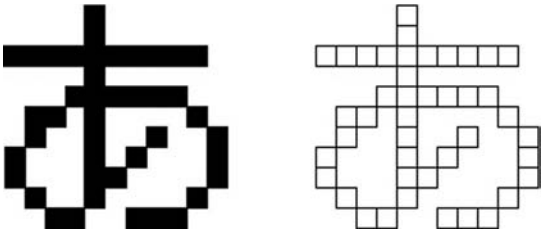

Figure 5.

New Alphabet typeface

to graphic design's shift from tangible to computer screen-based production. This digitally influenced typeface announced the beginnings of the shift in typography from "hands-on" to digital layout.

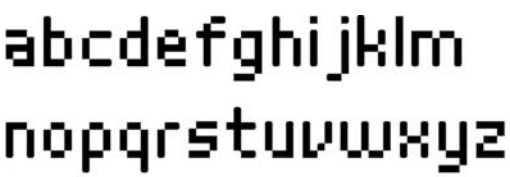
Today, we find ourselves in what I call the aesthetic of the pixel, which in turn is part of screenspace. Currently, there are countless fonts that are specifically designed to be read on the screen. These pixel fonts—with clever names such as Silkscreen, Seven-Net and Superpoint—are designed to be read on very small scales. Their geometry responds to the screen's matrix and, compared to the typeface Oakland, seems much more refined.

This then brings me back to the keitai screen's resolution and pixel dimensions. Most current keitai screen resolutions are around 132x176 pixels, with a few at 360x480 pixels. Color keitai screens range from the basic 256 colors to a crisp 266k colors. The various keitai built-in cameras can capture still images from 176x144 to an astonishing 640x480 pixels and some with even a few seconds of video.

With these achievements in high screen resolutions, KDDI Corp. and Okinawa Cellular released four keitai in August 2002 with built-in cameras that are able to capture up to 15 seconds of smooth running video and audio. Captured video can then be viewed, subtitles and voiceovers can be added, video can be attached to an e-mail and easily sent to another "Movie Keitai" or computer. These keitai take advantage of the third-generation CDMA2000 wireless network which has data transmission speeds of up to 144 kbps allowing captured images to be sent and downloaded smoothly.

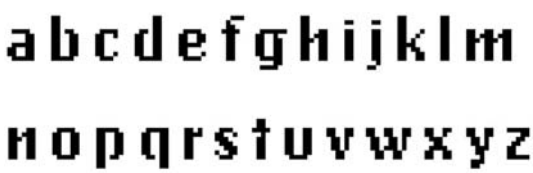
There are hundreds of paid subscription services for the keitai that provide everything from astrological information to financial transactions. All of these services have rich GUI's and some are animated. But probably one of the most interesting uses of graphics and interaction is the map service simply called "Keitai Map" provided by Zenrin. Enter a simple search query on your screen and up comes a vector map image that zooms in and out smoothly. The maps are clear and if used in tandem with one's built-in GPS you will never be lost in Tokyo's labyrinth of streets again.

Figure 5.



Stedelijk typeface

Figure 6.



Oakland typeface

Along with captured images, subscription services, and Japanese characters, an iconic graphic language has emerged for quick messaging on the keitai. Called "emoji," (a shorthand) it evolved from the use of text to make images that would represent a user's emotions. Examples: ^_^ represents the user is happy; ($_$) represents the user is greedy; and (o|o) represents the Japanese superhero Ultra man. There are now hundreds of little emoji 16x16 pixel icons, mostly static, some animated. Emoji has become hugely popular. A typical message—"Meet me for a beer at 7 p.m."—could consist of the emoji for a frosty beer mug and a clock showing 7 p.m. Emoji has become a new typography developed for the keitai.

In contrast to the personal graphics and text created on the keitai, graphics and type on the large LED screens are much more robust and often in full motion with sound, creating the ultimate experience of screenspace. Most screens are typically only a few meters across, but the huge screen called Q Eye, found in Shibuya, is a least six stories tall. Located on the Q Front[7] building in Shibuya, it is an example of architecture becoming a screen or a screen becoming architecture. On its front surface there is a large display made up of three separate screens containing more than 121,600 LED clusters broken into red, green and blue. Q Eye towers over pedestrians as they navigate the intersections around the JR Shibuya station. It is composed of three separate screens: two "banner" screens on the top and bottom and one main screen in the center. Since the screens are synchronized, they create the illusion of one large screen towering six stories tall. Q Eye seems to be always on and in constant motion, displaying videos of Japan's hottest pop stars to advertisements for Sony's new cameras. At night, the glow from its screens, along with the two other small screens in its vicinity, light up the streets, giving Shibuya an eerie feel as colors and images shift and move.

FUTURE TRENDS

As Tokyo's streets shine and flicker from the ever-popular keitai and newly constructed jumbo LED displays, major companies are developing the next generation of screens. Of particular interest for these researchers: improvement of screen resolution, energy usage, thinness, and flexibility. The focus on flexibility and thinness is evident in current research on organic electroluminescence (OEL) and E-ink's screens.

Electronic ink's (E-Ink's) main components consist of thousands of tiny microcapsules that have the diameter of 100 microns (about the width of a human hair). These microcapsules contain both positively and negatively charged particles of white and black color. When a positive electric field is applied to the microcapsule, the white particles become visible; when a negative charge is applied, the black particles become visible. With these microcapsules turning on and off, thousands are necessary to create an image. Arranged in a grid, they function in a similar fashion as a pixel on a computer screen.

These microcapsules are suspended in a liquid, allowing E-Ink to be printed on virtually any surface from plastic to metal. The main advantages that E-Ink demonstrates over current display technologies include low power usage, flexibility, durability, and readability. First introduced in 1999, E-Ink displays draw only 0.1 watts of power and only when changing its display; an E-Ink sign with static information draws no power.

Electronic paper, which is very similar to E-Ink, is being simultaneously developed by Xerox. First developed in the 1970s it functions in a similar manner to E-Ink, but has microscopic balls that are black on one side and white on the other. These balls rotate when an electrical charge is applied, showing either black or white.

E-Ink is currently more desirable because of its simplicity and cost compared to electronic paper, which also requires complicated wiring.

The main drawback with current E-Ink and electronic paper technology is that their screens are only monochromatic (multicolored screens are in development).

Organic electroluminescence displays (OEL) contain thin organic layers made of a carbon-based compound that illuminates brightly when an electric charge is applied. This allows for thin, flexible, cool (temperature), brightly glowing screens that operate on very low power. Monochromatic passive-matrix OEL screens are currently found everywhere from car stereos to keitai. Currently, full color active-matrix OEL displays, driven by thin film transistors (TFT), are limited in size due to production cost.

The future market potential for large OEL screens is tremendous. Major companies (e.g., Pioneer, Sony, Sanyo, Kodak, NEC, and Samsung) have been pouring millions of research dollars into perfecting the production and performance of large full color OEL active-matrix displays. From this research, Sanyo has developed and put into production a 260,000-color OEL screen for use with third-generation multimedia keitai currently found in Japan. This commitment by Sanyo indicates the future direction of keitai screen technology.

The real breakthrough will occur when full color OEL displays reach 10" (diagonal measurement) or more with screen resolutions of 800x600 pixels and greater. In 2001, Sony was the first to produce a prototype screen measuring 13" with a screen resolution of 800x600 pixels and measuring just 1.4 millimeters in thickness. Mass production of these large OEL screens will replace the cathode ray tube and current LCD monitors, bringing us one step closer to jumbo OEL screens.

Pioneer began mass production of monochromatic passive-matrix OEL displays in 1997. Used on Motorola cellphones, these passive-matrix screens do not need integrated circuits or a glass base, allowing the screen to be built on plastic. From this research, Pioneer has prototyped wearable plastic OEL screens attached to winter coats and has begun the mass production of small passive-matrix screens for PDAs.

The cutting edge research that is being done is essential for the future of screenspace. With E-Ink and electronic paper, screens will be more flexible and will require little maintenance and energy consumption. But the real future of screenspace relies upon the research in OEL display technology. With the possibilities of screens being incorporated into clothing and jumbo OEL screens (as well as meshing into newly constructed buildings) every surface has the potential to become a screen.

Along with this vast research being conducted by R&D labs of major companies, two artists—Ryota Kuwakubo and Sugihara Yuki—are expanding our ideas of screens and how we interact with them. Ryota Kuwakubo's work uses low-powered LED screens that are part of highly interactive devices. As users interact with the objects, elegantly designed circuits transmit signals to small clusters of LEDs creating patterns, symbols, and simple smiling faces. Bit-Man, designed to be worn around the neck while dancing, has an LED display of a man that responds to various sensors. The electronic man consists of a grid of red LEDs; the more Bit-Man is shaken, the longer and faster the electronic man dances. If Bit-Man is rotated in any direction, the LED man positions himself upright.

In contemporary Japan, Yuki Sugihara steps away from the traditional use and understanding of screens. She utilizes water as a "screen" to project light and images upon. Sugihara's work, titled "Head- Mounted Water Display," recently exhibited at NTT's Intercommunication Center in Tokyo. It invites viewers to step into a dark room. Inside, a cascading dome of water has been placed in the room's center and users step under the water dome one at a time to view colors and patterns projected upon the fluid surface of the dome. Sugihara brings the natural and the technological together in an elegant display of water, color, and image.

CONCLUSION

As of this writing, Japan leads the world in the development of the small personal keitai screens along with the jumbo LED displays. Times Square in New York City seems to be the only other location that rivals Shibuya with its saturation of screens. Major cellular phone companies in America are now realizing the popularity of wireless web access and have developed limited web access applications[8]. Movies such as *Minority Report* (2002), *The Time Machine* (2002), and *Brazil* (1985) present us with glimpses of what the future could hold for us and how we might interact with screenspace. Screens are becoming more affordable and sleek LCD flat screen monitors are more common, replacing the bulky CRT (cathode ray tube). Also, with research on OEL displays (E-Ink and the next generation of keitai) screenspace and cellspace will eventually become one.

As these technologies mature and new technologies are discovered, displays will not only get clearer, but will have the ability to be anywhere and everywhere. Screenspace and cellspace will become one, and urban landscapes will flicker brightly in the night sky.

ENDNOTES

1. Hertzian Space is used by Anthony Dunne and Fiona Raby to described the invisible spectrum of electromagnetic waves that are emitted from various devices.
2. Japanese for cellphone and translates to "portable".
3. Sha is short for photograph in Japanese.
4. As of July 2002, there were three large LED displays at Shibuya crossing.
5. Capsule hotels are typically for men only.
6. Hirigana and Katakana are phonetic characters where Kanji is more complex and each character represents various words depending on context.
7. Q eye is a LED screen located on the front of the Q front building at Shibuya crossing in Tokyo, Japan.
8. mMode from AT&T Wireless and PCS Vision from Sprint are bringing high-speed access to their cellular phone users. These

services allow web access, gaming, instant messaging, custom ring tones and images to be sent from on phone to the other.

Chapter 3.11
Audio Watermarking:
Properties, Techniques and Evaluation

Andrés Garay Acevedo
Georgetown University, USA

ABSTRACT

The recent explosion of the Internet as a collaborative medium has opened the door for people who want to share their work. Nonetheless, the advantages of such an open medium can pose very serious problems for authors who do not want their works to be distributed without their consent. As new methods for copyright protection are devised, expectations around them are formed and sometimes improvable claims are made. This chapter covers one such technology: audio watermarking. First, the field is introduced, and its properties and applications are discussed. Then, the most common techniques for audio watermarking are reviewed, and the framework is set for the objective measurement of such techniques. The last part of the chapter proposes a novel test and a set of metrics for thorough benchmarking of audio watermarking schemes. The development of such a benchmark constitutes a first step towards the standardization of the requirements and properties that such systems should display.

INTRODUCTION

The recent explosion of the Internet as a collaborative medium has opened the door for people who want to share their work. Nonetheless, the advantages of such an open medium can pose very serious problems for authors who do not want their works to be distributed without their consent. The digital nature of the information that traverses through modern networks calls for new and improved methods for copyright protection[1].

In particular, the music industry is facing several challenges (as well as opportunities) as it tries to adapt its business to the new medium. Content protection is a key factor towards a comprehensive information commerce infrastructure (Yeung, 1998), and the industry expects new technologies will help them protect against the misappropriation of musical content.

One such technology, digital watermarking, has recently brought a tide of publicity and controversy. It is an emerging discipline, derived from an older science: steganography, or the hiding of a secret message within a seemingly

innocuous cover message. In fact, some authors treat watermarking and steganography as equal concepts, differentiated only by their final purpose (Johnson, Duric, & Jajodia, 2001).

As techniques for digital watermarking are developed, claims about their performance are made public. However, different metrics are typically used to measure performance, making it difficult to compare both techniques and claims. Indeed, there are no standard metrics for measuring the performance of watermarks for digital audio. Robustness does not correspond to the same criteria among developers (Kutter & Petitcolas, 1999). Such metrics are needed before we can expect to see a commercial application of audio watermarking products with a provable performance.

The objective of this chapter is to propose a methodology, including performance metrics, for evaluating and comparing the performance of digital audio watermarking schemes. In order to do this, it is necessary first to provide a clear definition of what constitutes a watermark and a watermarking system in the context of digital audio. This is the topic of the second section, which will prove valuable later in the chapter, as it sets a framework for the development of the proposed test.

After a clear definition of a digital watermark has been presented, a set of key properties and applications of digital watermarks can be defined and discussed. This is done in the third section, along with a classification of audio watermarking schemes according to the properties presented. The importance of these properties will be reflected on the proposed tests, discussed later in the chapter. The survey of different applications of watermarking techniques gives a practical view of how the technology can be used in a commercial and legal environment. The specific application of the watermarking scheme will also determine the actual test to be performed to the system.

The fourth section presents a survey of specific audio watermarking techniques developed. Five general approaches are described: amplitude modification, dither watermarking, echo watermarking, phase distortion, and spread spectrum watermarking. Specific implementations of watermarking algorithms (i.e., test subjects) will be evaluated in terms of these categories[2].

The next three sections describe how to evaluate audio watermarking technologies based on three different parameters: fidelity, robustness, and imperceptibility. Each one of these parameters will be precisely defined and discussed in its respective section, as they directly reflect the interests of the three main actors involved in the communication process[3]: sender, attacker, and receiver, respectively.

Finally, the last section provides an account on how to combine the three parameters described above into a single performance measure of quality. It must be stated, however, that this measure should be dependant upon the desired application of the watermarking algorithm (Petitcolas, 2000).

The topics discussed in this chapter come not only from printed sources but also from very productive discussions with some of the active researchers in the field. These discussions have been conducted via e-mail, and constitute a rich complement to the still low number of printed sources about this topic. Even though the annual number of papers published on watermarking has been nearly doubling every year in the last years (Cox, Miller, & Bloom, 2002), it is still low. Thus it was necessary to augment the literature review with personal interviews.

WATERMARKING: A DEFINITION

Different definitions have been given for the term *watermarking* in the context of digital content. However, a very general definition is given by Cox et al. (2002), which can be seen as application independent: "We define watermarking as the practice of imperceptibly altering a Work to

embed a message about that Work". In this definition, the word *work* refers to a specific song, video or picture[4].

A crucial point is inferred by this definition, namely that the information hidden within the work, the watermark itself, contains information about the work where it is embedded. This characteristic sets a basic requirement for a watermarking system that makes it different from a general steganographic tool. Moreover, by distinguishing between embedded data that relate to the cover work and hidden data that do not, we can derive some of the applications and requirements of the specific method. This is exactly what will be done later.

Another difference that is made between watermarking and steganography is that the former has the additional notion of robustness against attacks (Kutter & Hartung, 2000). This fact also has some implications that will be covered later on.

Finally, if we apply Cox's definition of watermarking into the field of audio signal processing, a more precise definition, this time for audio watermarking, can be stated. Digital audio watermarking is defined as the process of "embedding a user specified bitsream in digital audio such that the addition of the watermark (bitstream) is perceptually insignificant" (Czerwinski, Fromm, & Hodes, 1999).

This definition should be complemented with the previous one, so that we do not forget the watermark information refers to the digital audio file.

Elements of an Audio Watermarking System

Embedded watermarks are recovered by running the inverse process that was used to embed them in the cover work, that is, the original work. This means that all watermarking systems consist of at least two generic building blocks: a watermark embedding system and a watermark recovery system.

Figure 1 shows a basic watermarking scheme, in which a watermark is both embedded and recovered in an audio file. As can be seen, this process might also involve the use of a secret key. In general terms, given the audio file A, the watermark W and the key K, the embedding process is a mapping of the form $A \times K \times W \rightarrow A'$

Conversely, the recovery or extraction process receives a tentatively watermarked audio file A', and a recovery key K' (which might be equal to K), and it outputs either the watermark W or a confidence measure about the existence of W (Petitcolas, Anderson, & G., 1999).

At this point it is useful to attempt a formal definition of a watermarking system, based on that of Katzenbeisser (2000), and which takes into account the architecture of the system. The quintuple $\xi = \langle C, W, K, D_k, E_k \rangle$, where C is the set of possible audio *covers*[5], W the set of *watermarks* with $|C| \geq |W|$, K the set of secret *keys*, $E_k: C \times K \times W \rightarrow C$ the embedding function and $D_k: C \times K \rightarrow W$ the extraction function, with the property that $D_k(E_k(c, k, w)\, k) = w$ for all $w \in W$, $c \in C$ and $k \in K$ is called a *secure audio watermarking system*.

Figure 1. Basic watermarking system

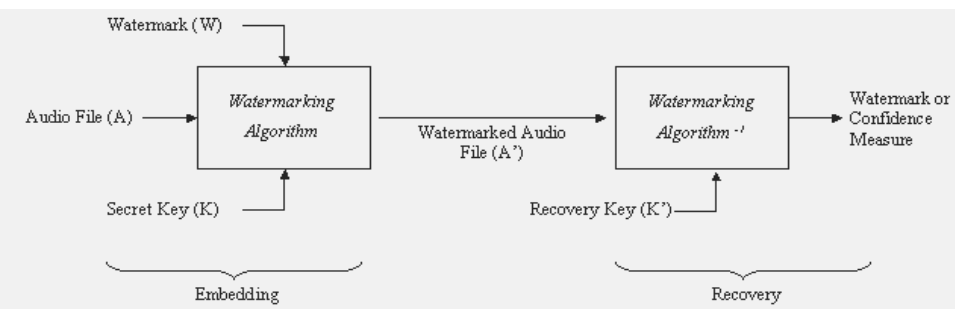

Figure 2. Watermark communication process

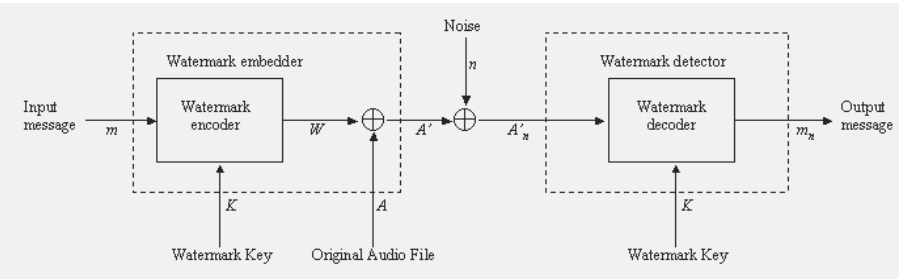


This definition is almost complete, but it fails to cover some special cases. Some differences might arise between a real world system, and the one just defined; for example, some detectors may not output the watermark *W* directly but rather report the existence of it. Nonetheless, it constitutes a good approximation towards a widely accepted definition of an audio watermarking system.

If one takes into account the small changes that a marking scheme can have, a detailed classification of watermarking schemes is possible. In this classification, the different schemes fall into three categories, depending on the set of inputs and outputs (Kutter & Hartung, 2000). Furthermore, a specific and formal definition for each scheme can be easily given by adapting the definition just given for an audio watermarking system.

Private watermarking systems require the original audio *A* file in order to attempt recovery of the watermark *W*. They may also require a copy of the embedded watermark and just yield a yes or no answer to the question: does *A′* contain *W*?

Semi-private watermarking schemes do not use the original audio file for detection, but they also answer the yes/no question shown above. This could be described by the relation $A' \times K \times W \rightarrow$ {"Yes", "No"}.

Public watermarking (also known as *blind* or *oblivious* watermarking) requires neither the original file *A*, nor the embedded watermark *W*. These systems just extract *n* bits of information from the watermarked audio file. As can be seen, if a key is used then this corresponds to the definition given for a *secure watermarking system*.

Watermark as a Communication Process

A watermarking process can be modeled as a communication process. In fact, this assumption is used throughout this chapter. This will prove to be beneficial in the next chapter when we differentiate between the requirements of the content owner and consumer. A more detailed description of this model can be found in Cox et al. (2002).

In this framework, the watermarking process is viewed as a transmission channel through which the watermark message is communicated. Here the cover work is just part of the channel. This is depicted in Figure 2, based on that from Cox et al. (2002).

In general terms, the embedding process consists of two steps. First, the watermark message *m* is mapped into an added pattern[6] W_a, of the same type and dimension as the cover work *A*. When watermarking audio, the watermark encoder produces an audio signal. This mapping may be done with a watermark key *K*. Next, W_a is embedded into the cover work in order to produce the watermarked audio file *A′*.

After the pattern is embedded, the audio file is processed in some way. This is modeled as the addition of noise to the signal, which yields a noisy work A'_n. The types of processing performed on

the work will be discussed later, as they are of no importance at this moment. However, it is important to state the presence of noise, as any transmission medium will certainly induce it.

The watermark detector performs a process that is dependant on the type of watermarking scheme. If the decoder is a *blind or public decoder*, then the original audio file *A* is not needed during the recovery process, and only the key *K* is used in order to decode a watermark message m_n. This is the case depicted in Figure 2, as it is the one of most interest to us.

Another possibility is for the detector to be *informed*. In this case, the original audio cover *A* must be extracted from A'_n in order to yield W_n, prior to running the decoding process. In addition, a confidence measure can be the output of the system, rather than the watermark message.

PROPERTIES, CLASSIFICATION AND APPLICATIONS

After a proper definition of a watermarking scheme, it is possible now to take a look at the fundamental properties that comprise a watermark. It can be stated that an ideal watermarking scheme will present all of the characteristics here detailed, and this ideal type will be useful for developing a quality test.

However, in practice there exists a fundamental trade-off that restricts watermark designers. This fundamental trade-off exists between three key variables: robustness, payload and perceptibility (Cox, Miller, Linnartz, & Kalker, 1999; Czerwinski et al., 1999; Johnson et al., 2001; Kutter & Petitcolas, 1999; Zhao, Koch, & Luo, 1998). The relative importance given to each of these variables in a watermarking implementation depends on the desired application of the system.

Fundamental Properties

A review of the literature quickly points out the properties that an ideal watermarking scheme should possess (Arnold, 2000; Boney, Tewfik & Hamdy, 1996; Cox, Miller, & Bloom, 2000; Cox et al., 1999, 2002; Kutter & Hartung, 2000; Kutter & Petitcolas, 1999; Swanson, Zhu, Tewfik, & Boney, 1998). These are now discussed.

Imperceptibility. "The watermark should not be noticeable … nor should [it] degrade the quality of the content" (Cox et al., 1999). In general, the term refers to a similarity between the original and watermarked versions of the cover work.

In the case of audio, the term *audibility* would be more appropriate; however, this could create some confusion, as the majority of the literature uses *perceptibility*. This is the same reason why the term *fidelity* is not used at this point, even though Cox et al. (1999) point out that if a watermark is truly imperceptible, then it can be removed by perceptually-based lossy compression algorithms. In fact, this statement will prove to be a problem later when trying to design a measure of watermark perceptibility. Cox's statement implies that some sort of perceptibility criterion must be used not only to design the watermark, but to quantify the distortion as well. Moreover, it implies that this distortion must be measured at the point where the audio file is being presented to the consumer/receiver.

If the distortion is measured at the receiver's end, it should also be measured at the sender's. That is, the distortion induced by a watermark must also be measured before any transmission process. We will refer to this characteristic at the sending end by using the term *fidelity.*

This distinction between the terms *fidelity* and *imperceptibility* is not common in the literature, but will be beneficial at a later stage. Differentiating between the amount and characteristics of the noise or distortion that a watermark introduces in a signal before and after the transmission process takes into account the different expectations that content owners and consumers have from the technology. However, this also implies that the metric used to evaluate this effect must be different at these points. This is exactly what will be done later on this chapter.

Artifacts introduced through a watermarking process are not only annoying and undesirable, but may also reduce or destroy the commercial value of the watermarked data (Kutter & Hartung, 2000). Nonetheless, the perceptibility of the watermark can increase when certain operations are performed on the cover signal.

Robustness refers to the ability to detect the watermark after common signal processing operations and hostile attacks. Examples of common operations performed on audio files include noise reduction, volume adjustment or normalization, digital to analog conversion, and so forth. On the other hand, a hostile attack is a process specifically designed to remove the watermark.

Not all watermarking applications require robustness against all possible signal processing operations. Only those operations likely to occur between the embedding of the mark and the decoding of it should be addressed. However, the number and complexity of attack techniques is increasing (Pereira, Voloshynovskiy, Madueño, Marchand-Maillet, & Pun, 2001; Voloshynovskiy, Pereira, Pun, Eggers, & Su, 2001), which means that more scenarios have to be taken into account when designing a system. A more detailed description of these attacks is given in the sixth section.

Robustness deals with two different issues; namely the presence and detection of the watermark after some processing operation. It is not necessary to remove a watermark to render it useless; if the detector cannot report the presence of the mark then the attack can be considered successful. This means that a watermarking scheme is robust when it is able to withstand a series of attacks that try to degrade the quality of the embedded watermark, up to the point where it's removed, or its recovery process is unsuccessful. "No such perfect method has been proposed so far, and it is not clear yet whether an absolutely secure watermarking method exists at all" (Kutter & Hartung, 2000).

Some authors prefer to talk about *tamper resistance* or even *security* when referring to hostile attacks; however, most of the literature encompasses this case under the term *robustness.*

The *effectiveness* of a watermarking system refers to the probability that the output of the embedder will be watermarked. In other words, it is the probability that a watermark detector will recognize the watermark immediately after inserting it in the cover work. What is most amazing about this definition is the implication that a watermarking system might have an effectiveness of less than 100%. That is, it is possible for a system to generate marks that are not fully recoverable even if no processing is done to the cover signal. This happens because perfect effectiveness comes at a very high cost with respect to other properties, such as perceptibility (Cox et al., 2002). When a known watermark is not successfully recovered by a detector it is said that a false negative, or type-II error, has occurred (Katzenbeisser, 2000).

Depending on the application, one might be willing to sacrifice some performance in exchange for other characteristics. For example, if extremely high fidelity is to be achieved, one might not be able to successfully watermark certain type of works without generating some kind of distortion. In some cases, the effectiveness can be determined analytically, but most of the time it has to be estimated by embedding a large set of works with a given watermark and then trying to extract that mark. However, the statistical characteristics of the test set must be similar to those of the works that will be marked in the real world using the algorithm.

Data payload. In audio watermarking this term refers to the number of embedded bits per second that are transmitted. A watermark that encodes *N* bits is referred to as an N-bit watermark, and can be used to embed 2^N different messages. It must be said that there is a difference between the encoded message *m*, and the actual bitstream that is embedded in the audio cover work. The

latter is normally referred to as a *pseudorandom* (PN) *sequence*.

Many systems have been proposed where only one possible watermark can be embedded. The detector then just determines whether the watermark is present or not. These systems are referred to as *one-bit watermarks*, as only two different values can be encoded inside the watermark message. In discussing the data payload of a watermarking method, it is also important to distinguish between the number of distinct watermarks that may be inserted, and the number of watermarks that may be detected by a single iteration with a given watermark detector. In many watermarking applications, each detector need not test for all the watermarks that might possibly be present (Cox et al., 1999). For example, one might insert two different watermarks into the same audio file, but only be interested in recovering the last one to be embedded.

Other Properties

Some of the properties reviewed in the literature are not crucial for testing purposes; however they must be mentioned in order to make a thorough description of watermarking systems.

- **False positive rate.** A false positive or type-I error is the detection of a watermark in a work that does not actually contain one. Thus a false positive rate is the expected number of false positives in a given number of runs of the watermark detector. Equivalently, one can detect the probability that a false positive will occur in a given detector run.
  In some applications a false positive can be catastrophic. For example, imagine a DVD player that incorrectly determines that a legal copy of a disk (for example a homemade movie) is a non-factory-recorded disk and refuses to play it. If such an error is common, then the reputation of DVD players and consequently their market can be seriously damaged.
- **Statistical invisibility.** This is needed in order to prevent unauthorized detection and/or removal. Performing statistical tests on a set of watermarked files should not reveal any information about the nature of the embedded information, nor about the technique used for watermarking (Swanson et al., 1998). Johnson et al. (2001) provide a detailed description of known signatures that are created by popular information hiding tools. Their techniques can be also extended for use in some watermarking systems.
- **Redundancy.** To ensure robustness, the watermark information is embedded in multiple places on the audio file. This means that the watermark can usually be recovered from just a small portion of the watermarked file.
- **Compression ratio,** or similar compression characteristics as the original file. Audio files are usually compressed using different schemes, such as MPEG-Layer 3 audio compression. An audio file with an embedded watermark should yield a similar compression ratio as its unmarked counterpart, so that its value is not degraded. Moreover, the compression process should not remove the watermark.
- **Multiple watermarks.** Multiple users should be able to embed a watermark into an audio file. This means that a user has to ideally be able to embed a watermark without destroying any preexisting ones that might be already residing in the file. This must hold true even if the watermarking algorithms are different.
- **Secret keys.** In general, watermarking systems should use one or more cryptographically secure keys to ensure that the watermark cannot be manipulated or erased. This is important because once a watermark can be read by someone, this same person might alter it since both the location and embedding algorithm of the mark will be known (Kutter & Hartung, 2000). It is not

safe to assume that the embedding algorithm is unknown to the attacker.

As the security of the watermarking system relies in part on the use of secret keys, the *keyspace* must be large, so that a brute force attack is impractical. In most watermarking systems the key is the PN-pattern itself, or at least is used as a seed in order to create it. Moreover, the watermark message is usually encrypted first using a cipher key, before it is embedded using the watermark key. This practice adds security at two different levels. In the highest level of secrecy, the user cannot read or decode the watermark, or even detect its presence. The second level of secrecy permits any user to detect the presence of the watermark, but the data cannot be decoded without the proper key. Watermarking systems in which the key is known to various detectors are referred to as unrestricted-key watermarks. Thus, algorithms for use as unrestricted-key systems must employ the same key for every piece of data (Cox et al., 1999). Those systems that use a different key for each watermark (and thus the key is shared by only a few detectors) are known as restricted-key watermarks.

- **Computational cost.** The time that it takes for a watermark to be embedded and detected can be a crucial factor in a watermarking system. Some applications, such as broadcast monitoring, require real time watermark processing and thus delays are not acceptable under any circumstances. On the other hand, for court disputes (which are rare), a detection algorithm that takes hours is perfectly acceptable as long as the effectiveness is high.

Additionally, the number of embedders and detectors varies according to the application. This fact will have an effect on the *cost* of the watermarking system. Applications such as DVD copy control need few embedders but a detector on each DVD player; thus the cost of recovering should be very low, while that of embedding could be a little higher[7]. Whether the algorithms are implemented as plug-ins or dedicated hardware will also affect the economics of deploying a system.

Different Types of Watermarks

Even though this chapter does not relate to all kinds of watermarks that will be defined, it is important to state their existence in order to later derive some of the possible applications of watermarking systems.

- **Robust watermarks** are simply watermarks that are robust against attacks. Even if the existence of the watermark is known, it should be difficult for an attacker to destroy the embedded information without the knowledge of the key8. An implication of this fact is that the amount of data that can be embedded (also known as the payload) is usually smaller than in the case of steganographic methods. It is important to say that watermarking and steganographic methods are more complementary than competitive.
- **Fragile watermarks** are marks that have only very limited robustness (Kutter & Hartung, 2000). They are used to detect modifications of the cover data, rather than convey inerasable information, and usually become invalid after the slightest modification of a work. Fragility can be an advantage for authentication purposes. If a very fragile mark is detected intact in a work, we can infer that the work has probably not been altered since the watermark was embedded (Cox et al., 2002). Furthermore, even semi-fragile watermarks can help localize the exact location where the tampering of the cover work occurred.
- **Perceptible watermarks,** as the name states, are those that are easily perceived by

the user. Although they are usually applied to images (as visual patterns or logos), it is not uncommon to have an audible signal overlaid on top of a musical work, in order to discourage illegal copying. As an example, the IBM Digital Libraries project (Memon & Wong, 1998; Mintzer, Magerlein, & Braudaway, 1996) has developed a visible watermark that modifies the brightness of an image based on the watermark data and a secret key. Even though perceptible watermarks are important for some special applications, the rest of this chapter focuses on imperceptible watermarks, as they are the most common.

- **Bitstream watermarks** are marks embedded directly into compressed audio (or video) material. This can be advantageous in environments where compressed bitstreams are stored in order to save disk space, like Internet music providers.
- **Fingerprinting** and labeling denote special applications of watermarks. They relate to watermarking applications where information such as the creator or recipient of the data is used to form the watermark. In the case of fingerprinting, this information consists of a unique code that uniquely identifies the recipient, and that can help to locate the source of a leak in confidential information. In the case of labeling, the information embedded is a unique data identifier, of interest for purposes such as library retrieving. A more thorough discussion is presented in the next section.

Watermark Applications

In this section the seven most common application for watermarking systems are presented. What is more important, all of them relate to the field of audio watermarking. It must be kept in mind that each of these applications will require different priorities regarding the watermark's properties that have just been reviewed.

- **Broadcast monitoring.** Different individuals are interested in broadcast verification. Advertisers want to be sure that the ads they pay for are being transmitted; musicians want to ensure that they receive royalty payments for the air time spent on their works.

  While one can think about putting human observers to record what they see or hear on a broadcast, this method becomes costly and error prone. Thus it is desirable to replace it with an automated version, and digital watermarks can provide a solution. By embedding a unique identifier for each work, one can monitor the broadcast signal searching for the embedded mark and thus compute the air time. Other solutions can be designed, but watermarking has the advantage of being compatible with the installed broadcast equipment, since the mark is included within the signal and does not occupy extra resources such as other frequencies or header files. Nevertheless, it is harder to embed a mark than to put it on an extra header, and content quality degradation can be a concern.
- **Copyright owner identification.** Under U.S. law, the creator of an original work holds copyright to it the instant the work is recorded in some physical form (Cox et al., 2002). Even though it is not necessary to place a copyright notice in distributed copies of work, it is considered a good practice, since a court can award more damages to the owner in the case of a dispute.

  However, textual copyright notices[9] are easy to remove, even without intention. For example, an image may be cropped prior to publishing. In the case of digital audio the problem is even worse, as the copyright notice is not visible at all times.

  Watermarks are ideal for including copyright notices into works, as they can be both imperceptible and inseparable from the cover

that contains them (Mintzer, Braudaway, & Bell, 1998). This is probably the reason why copyright protection is the most prominent application of watermarking today (Kutter & Hartung, 2000). The watermarks are used to resolve rightful ownership, and thus require a very high level of robustness (Arnold, 2000). Furthermore, additional issues must be considered; for example, the marks must be unambiguous, as other parties can try to embed counterfeit copyright notices. Nonetheless, it must be stated that the legal impact of watermark copyright notices has not yet been tested in court.

- **Proof of ownership.** Multimedia owners may want to use watermarks not just to identify copyright ownership, but also to actually prove ownership. This is something that a textual notice cannot easily do, since it can be forged.

  One way to resolve an ownership dispute is by using a central repository, where the author registers the work prior to distribution. However, this can be too costly[10] for many content creators. Moreover, there might be lack of evidence (such as sketch or film negatives) to be presented at court, or such evidence can even be fabricated.

  Watermarks can provide a way for authenticating ownership of a work. However, to achieve the level of security required for proof of ownership, it is probably necessary to restrict the availability of the watermark detector (Cox et al., 2002). This is thus not a trivial task.
- **Content authentication.** In authentication applications the objective is to detect modifications of the data (Arnold, 2000). This can be achieved with fragile watermarks that have low robustness to certain modifications. This proves to be very useful, as it is becoming easier to tamper with digital works in ways that are difficult to detect by a human observer.

  The problem of authenticating messages has been well studied in cryptography; however, watermarks are a powerful alternative as the signature is embedded directly into the work. This eliminates the problem of making sure the signature stays with the work. Nevertheless, the act of embedding the watermark must not change the work enough to make it appear invalid when compared with the signature. This can be accomplished by separating the cover work in two parts: one for which the signature is computed, and the other where it is embedded.

  Another advantage of watermarks is that they are modified along with the work. This means that in certain cases the location and nature of the processing within the audio cover can be determined and thus inverted. For example, one could determine if a lossy compression algorithm has been applied to an audio file[11].
- **Transactional watermarks.** This is an application where the objective is to convey information about the legal recipient of digital data, rather than the source of it. This is done mainly to identify single distributed copies of data, and thus monitor or trace back illegally produced copies of data that may circulate12.

  The idea is to embed a unique watermark in each distributed copy of a work, in the process we have defined as fingerprinting. In these systems, the watermarks must be secure against a collusion attack, which is explained in the sixth section, and sometimes have to be extracted easily, as in the case of automatic Web crawlers that search for pirated copies of works.
- **Copy control/device control.** Transactional watermarks as well as watermarks for monitoring, identification, and proof of ownership do not prevent illegal copying (Cox et al., 2000). Copy protection is difficult to achieve in open systems, but might be desirable in

proprietary ones. In such systems it is possible to use watermarks to indicate if the data can be copied or not (Mintzer et al., 1998).

The first and strongest line of defense against illegal copying is encryption, as only those who possess the decryption key can access the content. With watermarking, one could do a very different process: allow the media to be perceived, yet still prevent it from being recorded. If this is the case, a watermark detector must be included on every manufactured recorder, preferably in a tamper resistant device. This constitutes a serious nontechnical problem, as there is no natural incentive for recording equipment manufacturers to include such a detector on their machines. This is due to the fact that the value of the recorder is reduced from the point of view of the consumer.

Similarly, one could implement **play control,** so that illegal copies can be made but not played back by compliant equipment. This can be done by checking a media signature, or if the work is properly encrypted for example. By mixing these two concepts, a buyer will be left facing two possibilities: buying a compliant device that cannot play pirated content, or a noncompliant one that can play pirated works but not legal ones.

In a similar way, one could control a playback device by using embedded information in the media they reproduce. This is known as device control. For example, one could signal how a digital audio stream should be equalized, or even extra information about the artist. A more extreme case can be to send information in order to update the firmware of the playback device while it is playing content, or to order it to shut down at a certain time. This method is practical, as the need for a signaling channel can be eliminated.

- **Covert communication.** Even though it contradicts the definition of watermark given before, some people may use watermarking systems in order to hide data and communicate secretly. This is actually the realm of steganography rather than watermarking, but many times the boundaries between these two disciplines have been blurred. Nonetheless, in the context of this chapter, the hidden message is not a watermark but rather a robust covert communication.

  The use of watermarks for hidden annotation (Zhao et al., 1998), or labeling, constitutes a different case, where watermarks are used to create hidden labels and annotations in content such as medical imagery or geographic maps, and indexes in multimedia content for retrieval purposes. In these cases, the watermark requirements are specific to the actual media where the watermark will be embedded. Using a watermark that distorts a patient's radiography can have serious legal consequences, while the recovery speed is crucial in multimedia retrieval.

AUDIO WATERMARKING TECHNIQUES

In this section the five most popular techniques for digital audio watermarking are reviewed. Specifically, the different techniques correspond to the methods for merging (or inserting) the cover data and the watermark pattern into a single signal, as was outlined in the communication model of the second section.

There are two critical parameters to most digital audio representations: sample quantization method and temporal sampling rate. Data hiding in audio signals is especially challenging, because the human auditory system (HAS) operates over a wide dynamic range. Sensitivity to additive random noise is acute. However, there are some "holes" available. While the HAS has a large

dynamic range, it has a fairly small differential range (Bender, Gruhl, Morimoto, & Lu, 1996). As a result, loud sounds tend to mask out quiet sounds. This effect is known as *masking*, and will be fully exploited in some of the techniques presented here (Swanson et al., 1998).

These techniques do not correspond to the actual implementation of commercial products that are available, but rather constitute the basis for some of them. Moreover, most real world applications can be considered a particular case of the general methods described below.

Finally, it must be stated that the methods explained are specific to the domain of audio watermarking. Several other techniques that are very popular for hiding marks in other types of media, such as discrete cosine transform (DCT) coefficient quantization in the case of digital images, are not discussed. This is done because the test described in the following sections is related only to watermarking of digital audio.

Amplitude Modification

This method, also known as *least significant bit (LSB) substitution*, is both common and easy to apply in both steganography and watermarking (Johnson & Katzenbeisser, 2000), as it takes advantage of the quantization error that usually derives from the task of digitizing the audio signal.

As the name states, the information is encoded into the least significant bits of the audio data. There are two basic ways of doing this: the lower order bits of the digital audio signal can be fully substituted with a pseudorandom (PN) sequence that contains the watermark message *m*, or the PN-sequence can be embedded into the lower order bitstream using the output of a function that generates the sequence based on both the n^{th} bit of the watermark message and the n^{th} sample of the audio file (Bassia & Pitas, 1998; Dugelay & Roche, 2000).

Ideally, the embedding capacity of an audio file with this method is 1 kbps per 1 kHz of sampled data. That is, if a file is sampled at 44 kHz then it is possible to embed 44 kilobits on each second of audio. In return for this large channel capacity, audible noise is introduced. The impact of this noise is a direct function of the content of the host signal. For example, crowd noise during a rock concert would mask some of the noise that would be audible in a string quartet performance. Adaptive data attenuation has been used to compensate for this variation in content (Bender et al., 1996). Another option is to shape the PN-sequence itself so that it matches the audio masking characteristics of the cover signal (Czerwinski et al., 1999).

The major disadvantage of this method is its poor immunity to manipulation. Encoded information can be destroyed by channel noise, resampling, and so forth, unless it is encoded using redundancy techniques. In order to be robust, these techniques reduce the data rate, often by one to two orders of magnitude. Furthermore, in order to make the watermark more robust against localized filtering, a pseudorandom number generator can be used to spread the message over the cover in a random manner. Thus, the distance between two embedded bits is determined by a secret key (Johnson & Katzenbeisser, 2000). Finally, in some implementations the PN-sequence is used to retrieve the watermark from the audio file. In this way, the watermark acts at the same time as the key to the system.

Recently proposed systems use amplitude modification techniques in a transform space rather than in the time (or spatial) domain. That is, a transformation is applied to the signal, and then the least significant bits of the coefficients representing the audio signal *A* on the transform domain are modified in order to embed the watermark *W*. After the embedding, the inverse transformation is performed in order to obtain the watermarked audio file *A'*. In this case, the technique is also known as *coefficient quantization*. Some of the transformations used for watermarking are the

discrete Fourier transform (DFT), discrete cosine transform (DCT), Mellin-Fourier transform, and wavelet transform (Dugelay & Roche, 2000). However, their use is more popular in the field of image and video watermarking.

Dither Watermarking

Dither is a noise signal that is added to the input audio signal to provide better sampling of that input when digitizing the signal (Czerwinski et al., 1999). As a result, distortion is practically eliminated, at the cost of an increased noise floor.

To implement dithering, a noise signal is added to the input audio signal with a known probability distribution, such as Gaussian or triangular. In the particular case of dithering for watermark embedding, the watermark is used to modulate the dither signal. The host signal (or original audio file) is quantized using an associated dither quantizer (RLE, 1999). This technique is known as *quantization index modulation* (QIM) (Chen & Wornell, 2000).

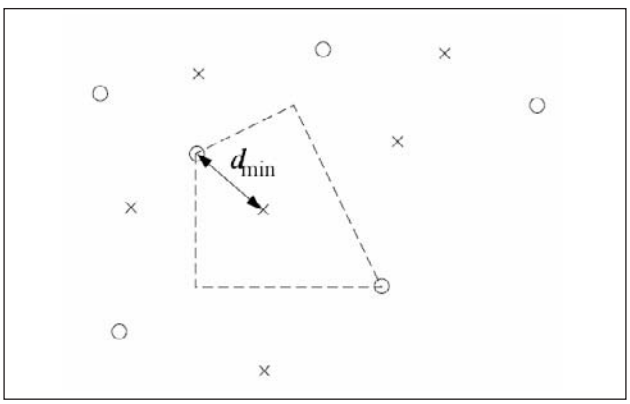
For example, if one wishes to embed one bit (m=1 or m=2) in the host audio signal A then one would use two different quantizers, each one representing a possible value for m. If the two quantizers are shifted versions of each other, then they are called *dither quantizers,* and the process is that of *dither modulation.* Thus, QIM refers to embedding information by first modulating an index or sequence of indices with the embedded information and then quantizing the host signal with the associated quantizer or sequence of quantizers (Chen & Wornell, 1999).

A graphical view of this technique is shown in Figure 3, taken from Chen (2000). Here, the points marked with X's and O's belong to two different quantizers, each with an associated index; that is, each one embedding a different value. The distance d_{min} can be used as an informal measure of robustness, while the size of the quantization cells (one is shown in the figure) measures the distortion on the audio file. If the watermark message m=1, then the audio signal is quantized to the nearest X. If m=2 then it is quantized to the nearest O.

The two quantizers must not intersect, as can be seen in the figure. Furthermore, they have a discontinuous nature. If one moves from the interior of the cell to its exterior, then the corresponding value of the quantization function jumps from an X in the cell's interior to one X on its exterior. Finally, as noted above, the number of quantizers in the ensemble determines the information-embedding rate (Chen & Wornell, 2000).

As was said above, in the case of dither modulation, the quantization cells of any quantizer in the ensemble are shifted versions of the cells of any other quantizer being used as well. The

Figure 3. A graphical view of the QIM technique



shifts traditionally correspond to pseudorandom vectors called the *dither* vectors. For the task of watermarking, these vectors are modulated with the watermark, which means that each possible embedded signal maps uniquely to a different dither vector. The host signal A is then quantized with the resulting dithered quantizer in order to crate the watermarked audio signal A'.

Echo Watermarking

Echo watermarking attempts to embed information on the original discrete audio signal $A(t)$ by introducing a repeated version of a component of the audio signal with small enough offset (or delay), initial amplitude and decay rate $\alpha A(t - \Delta t)$ to make it imperceptible. The resulting signal can be then expressed as $A'(t) = A(t) + \alpha A(t - \Delta t)$.

In the most basic echo watermarking scheme, the information is encoded in the signal by modifying the delay between the signal and the echo. This means that two different values Δt and $\Delta t'$ are used in order to encode either a zero or a one. Both offset values have to be carefully chosen in a way that makes the watermark both inaudible and recoverable (Johnson & Katzenbeisser, 2000).

As the offset between the original and the echo decreases, the two signals blend. At a certain point, the human ear cannot distinguish between the two signals. The echo is perceived as added resonance (Bender et al., 1996). This point is hard to determine exactly, as it depends on many factors such as the quality of the original recording, the type of sound being echoed, and the listener. However, in general one can expect the value of the offset Δt to be around one millisecond.

Since this scheme can only embed one bit in a signal, a practical approach consists of dividing the audio file into various blocks prior to the encoding process. Then each block is used to encode a bit, with the method described above. Moreover, if consecutive blocks are separated by a random number of unused samples, the detection and removal of the watermark becomes more difficult (Johnson & Katzenbeisser, 2000). Finally, all the blocks are concatenated back, and the watermarked audio file A' is created. This technique results in an embedding rate of around 16 bits per second without any degradation of the signal. Moreover, in some cases the resonance can even create a richer sound.

For watermark recovery, a technique known as *cepstrum autocorrelation* is used (Czerwinski et al., 1999). This technique produces a signal with two pronounced amplitude humps or *spikes*. By measuring the distance between these two spikes, one can determine if a one or a zero was initially encoded in the signal. This recovery process has the benefit that the original audio file A is not needed. However, this benefit also becomes a drawback in that the scheme presented here is susceptible to attack. This will be further explained in the sixth section.

Phase Coding

It is known that the human auditory system is less sensitive to the phase components of sound than to the noise components, a property that is exploited by some audio compression schemes. Phase coding (or phase distortion) makes use of this characteristic as well (Bender et al., 1996; Johnson & Katzenbeisser, 2000).

The method works by substituting the phase of the original audio signal A with one of two reference phases, each one encoding a bit of information. That is, the watermark data W is represented by a phase shift in the phase of A.

The original signal A is split into a series of short sequences A_i, each one of length l. Then a discrete Fourier transform (DFT) is applied to each one of the resulting segments. This transforms the signal representation from the time domain to the frequency domain, thus generating a matrix of phases Φ and a matrix of Fourier transform magnitudes.

The phase shifts between consecutive signal segments must be preserved in the watermarked

file *A′*. This is necessary because the human auditory system is very sensitive to relative phase differences, but not to absolute phase changes. In other words, the phase coding method works by substituting the phase of the initial audio segment with a reference phase that represents the data. After this, the phase of subsequent segments is adjusted in order to preserve the relative phases between them (Bender et al., 1996).

Given this, the embedding process inserts the watermark information in the phase vector of the first segment of *A*, namely $\vec{\Phi}_0$. Then it creates a new phase matrix Φ′, using the original phase differences found in Φ.

After this step, the original matrix of Fourier transform magnitudes is used alongside the new phase matrix Φ′ to construct the watermarked audio signal *A′*, by applying the inverse Fourier transform (that is, converting the signal back to the time domain). At this point, the absolute phases of the signal have been modified, but their relative differences are preserved. Throughout the process, the matrix of Fourier amplitudes remains constant. Any modifications to it could generate intolerable degradation (Dugelay & Roche, 2000).

In order to recover the watermark, the length of the segments, the DFT points, and the data interval must be known at the receiver. When the signal is divided into the same segments that were used for the embedding process, the following step is to calculate the DFT for each one of these segments. Once the transformation has been applied, the recovery process can measure the value of vector $\vec{\Phi}_0$ and thereby restore the originally encoded value for *W*.

With phase coding, an embedding rate between eight and 32 bits per second is possible, depending on the audio context. The higher rates are usually achieved when there is a noisy background in the audio signal. A higher embedding rate can result in phase dispersion, a distortion[13] caused by a break in the relationship of the phases between each of the frequency components (Bender et al., 1996).

Spread Spectrum Watermarking

Spread spectrum techniques for watermarking borrow most of the theory from the communications community (Czerwinski et al., 1999). The main idea is to embed a narrow-band signal (the watermark) into a wide-band channel (the audio file). The characteristics of both *A* and *W* seems to suit this model perfectly. In addition, spread spectrum techniques offer the possibility of protecting the watermark privacy by using a secret key to control the pseudorandom sequence generator that is needed in the process.

Generally, the message used as the watermark is a narrow band signal compared to the wide band of the cover (Dugelay & Roche, 2000; Kirovski & Malvar, 2001). Spread spectrum techniques allow the frequency bands to be matched before embedding the message. Furthermore, high frequencies are relevant for the invisibility of the watermark but are inefficient as far as robustness is concerned, whereas low frequencies have the opposite characteristics. If a low energy signal is embedded on each of the frequency bands, this conflict is partially solved. This is why spread spectrum techniques are valuable not only for robust communication but for watermarking as well.

There are two basic approaches to spread spectrum techniques: *direct sequence* and *frequency hopping*. In both of these approaches the idea is to spread the watermark data across a large frequency band, namely the entire audible spectrum.

In the case of direct sequence, the cover signal *A* is modulated by the watermark message *m* and a pseudorandom (PN) noise sequence, which has a wide frequency spectrum. As a consequence, the spectrum of the resulting message *m′* is spread over the available band. Then, the spread message *m′* is attenuated in order to obtain the watermark *W*. This watermark is then added to the original file, for example as additive random noise, in order to obtain the watermarked version *A′*. To keep the noise level down, the attenuation

performed to *m′* should yield a signal with about 0.5% of the dynamic range of the cover file *A* (Bender et al., 1996).

In order to recover the watermark, the watermarked audio signal *A′* is modulated with the PN-sequence to remove it. The demodulated signal is then *W*. However, some keying mechanisms can be used when embedding the watermark, which means that at the recovery end a detector must also be used. For example, if bi-phase shift keying is used when embedding *W*, then a phase detector must be used at the recovery process (Czerwinski et al., 1999).

In the case of *frequency hopping*, the cover frequency is altered using a random process, thus describing a wide range of frequency values. That is, the frequency-hopping method selects a pseudorandom subset of the data to be watermarked. The watermark *W* is then attenuated and merged with the selected data using one of the methods explained in this chapter, such as coefficient quantization in a transform domain. As a result, the modulated watermark has a wide spectrum.

For the detection process, the pseudorandom generator used to alter the cover frequency is used to recover the parts of the signal where the watermark is hidden. Then the watermark can be recovered by using the detection method that corresponds to the embedding mechanism used.

A crucial factor for the performance of spread spectrum techniques is the synchronization between the watermarked audio signal *A′* and the PN-sequence (Dugelay & Roche, 2000; Kirovski & Malvar, 2001). This is why the particular PN-sequence used acts as a key to the recovery process. Nonetheless, some attacks can focus on this delicate aspect of the model.

MEASURING FIDELITY

Artists, and digital content owners in general, have many reasons for embedding watermarks in their copyrighted works. These reasons have been stated in the previous sections. However, there is a big risk in performing such an operation, as the quality of the musical content might be degraded to a point where its value is diminished. Fortunately, the opposite is also possible and, if done right, digital watermarks can add value to content (Acken, 1998).

Content owners are generally concerned with the degradation of the cover signal quality, even more than users of the content (Craver, Yeo, & Yeung, 1998). They have access to the unwatermarked content with which to compare their audio files. Moreover, they have to decide between the amount of tolerance in quality degradation from the watermarking process and the level of protection that is achieved by embedding a stronger signal. As a restriction, an embedded watermark has to be detectable in order to be valuable.

Given this situation, it becomes necessary to measure the impact that a marking scheme has on an audio signal. This is done by measuring the fidelity of the watermarked audio signal *A′*, and constitutes the first measure that is defined in this chapter.

As fidelity refers to the similitude between an original and a watermarked signal, a statistical metric must be used. Such a metric will fall in one of two categories: difference metrics or correlation metrics.

Difference metrics, as the name states, measure the difference between the undistorted original audio signal *A* and the distorted watermarked signal *A′*. The popularity of these metrics is derived from their simplicity (Kutter & Petitcolas, 1999). In the case of digital audio, the most common difference metric used for quality evaluation of watermarks is the *signal to noise ratio* (SNR). This is usually measured in decibels (dB), so SNR(dB) = 10 $\log_{10}$ (SNR).

The signal to noise ratio, measured in decibels, is defined by the formula:

$$SNR(dB) = 10\log_{10}\frac{\sum_n A_n^2}{\sum_n (A_n - A'_n)^2}$$

where A_n corresponds to the n^{th} sample of the original audio file A, and A'_n to the n^{th} sample of the watermarked signal A'. This is a measure of quality that reflects the quantity of distortion that a watermark imposes on a signal (Gordy & Burton, 2000).

Another common difference metric is the *peak signal to noise ratio* (PSNR), which measures the maximum signal to noise ratio found on an audio signal. The formula for the PSNR, along with some other difference metrics found in the literature are presented in Table 1 (Kutter & Hartung, 2000; Kutter & Petitcolas, 1999).

Although the tolerable amount of noise depends on both the watermarking application and the characteristics of the unwatermarked audio signal, one could expect to have perceptible noise distortion for SNR values of 35dB (Petitcolas & Anderson, 1999).

Correlation metrics measure distortion based on the statistical correlation between the original and modified signals. They are not as popular as the difference distortion metrics, but it is important to state their existence. Table 2 shows the most important of these.

For the purpose of audio watermark benchmarking, the use of the *signal to noise ratio* (SNR) should be used to measure the fidelity of the watermarked signal with respect to the original. This decision follows most of the literature that deals with the topic (Gordy & Burton, 2000; Kutter & Petitcolas, 1999, 2000; Petitcolas & Anderson,

Table 1. Common difference distortion metrics

Maximum Difference	$MD = \max \mid A_n - A'_n \mid$
Average Absolute Difference	$AD = \frac{1}{N}\sum_n \mid A_n - A'_n \mid$
Normalized Average Absolute Difference	$NAD = \sum_n \mid A_n - A'_n \mid / \sum_n \mid A_n \mid$
Mean Square Error	$MSE = \frac{1}{N}\sum_n (A_n - A'_n)^2$
Normalized Mean Square Error	$NMSE = \sum_n (A_n - A'_n)^2 / \sum_n A_n^2$
LP-Norm	$LP = \left(\frac{1}{N}\sum_n \mid A_n - A'_n \mid \right)^{1/p}$
Laplacian Mean Square Error	$LMSE = \sum_n (\nabla^2 A_n - \nabla^2 A'_n)^2 / \sum_n (\nabla^2 A_n)^2$
Signal to Noise Ratio	$SNR = \sum_n A_n^2 / \sum_n (A_n - A'_n)^2$
Peak Signal to Noise Ratio	$PSNR = N \max_n A_n^2 / \sum_n (A_n - A'_n)^2$
Audio Fidelity	$AF = 1 - \sum_n (A_n - A'_n)^2 / \sum_n A_n^2$

Table 2. Correlation distortion metrics

Normalized Cross-Correlation	$NC = \sum_n A_n \tilde{A}_n / \sum_n A_n^2$
Correlation Quality	$CQ = \sum_n A_n \tilde{A}_n / \sum_n A_n$

1999). Nonetheless, in this measure the term *noise* refers to statistical noise, or a deviation from the original signal, rather than to perceived noise on the side of the hearer. This result is due to the fact that the SNR is not well correlated with the human auditory system (Kutter & Hartung, 2000). Given this characteristic, the effect of perceptual noise needs to be addressed later.

In addition, when a metric that outputs results in decibels is used, comparisons are difficult to make, as the scale is not linear but rather logarithmic. This means that it is more useful to present the results using a normalized quality rating. The ITU-R Rec. 500 quality rating is perfectly suited for this task, as it gives a quality rating on a scale of 1 to 5 (Arnold, 2000; Piron et al., 1999). Table 3 shows the rating scale, along with the quality level being represented.

This quality rating is computed by using the formula:

$$Quality = F = \frac{5}{1 + N * SNR}$$

where N is a normalization constant and SNR is the measured signal to noise ratio. The resulting value corresponds to the fidelity F of the watermarked signal.

Table 3. ITU-R Rec. 500 quality rating

Rating	Impairment	Quality
5	Imperceptible	Excellent
4	Perceptible, not annoying	Good
3	Slightly annoying	Fair
2	Annoying	Poor
1	Very annoying	Bad

Data Payload

The fidelity of a watermarked signal depends on the amount of embedded information, the strength of the mark, and the characteristics of the host signal. This means that a comparison between different algorithms must be made under equal conditions. That is, while keeping the payload fixed, the fidelity must be measured on the same audio cover signal for all watermarking techniques being evaluated.

However, the process just described constitutes a single measure event and will not be representative of the characteristics of the algorithms being evaluated, as results can be biased depending on the chosen parameters. For this reason, it is important to perform the tests using a variety of audio signals, with changing size and nature (Kutter & Petitcolas, 2000). Moreover, the test should also be repeated using different keys.

The amount of information that should be embedded is not easy to determine, and depends on the application of the watermarking scheme. In Kutter and Petitcolas (2000) a message length of 100 bits is used on their test of image watermarking systems as a representative value. However, some secure watermarking protocols might need a bigger payload value, as the watermark W could include a cryptographic signature for both the audio file A, and the watermark message m in order to be more secure (Katzenbeisser & Veith, 2002). Given this, it is recommended to use a longer watermark bitstream for the test, so that a

real world scenario is represented. A watermark size of 128 bits is big enough to include two 56-bit signatures and a unique identification number that identifies the owner.

Speed

Besides fidelity, the content owner might be interested in the time it takes for an algorithm to embed a mark (Gordy & Burton, 2000). Although speed is dependent on the type of implementation (hardware or software), one can suppose that the evaluation will be performed on software versions of the algorithms. In this case, it is a good practice to perform the test on a machine with similar characteristics to the one used by the end user (Petitcolas, 2000). Depending on the application, the value for the time it takes to embed a watermark will be incorporated into the results of the test. This will be done later, when all the measures are combined together.

MEASURING ROBUSTNESS

Watermarks have to be able to withstand a series of signal operations that are performed either intentionally or unintentionally on the cover signal and that can affect the recovery process. Given this, watermark designers try to guarantee a minimum level of robustness against such operations. Nonetheless, the concept of robustness is ambiguous most of the time and thus claims about a watermarking scheme being robust are difficult to prove due to the lack of testing standards (Craver, Perrig, & Petitcolas, 2000).

By defining a standard metric for watermark robustness, one can then assure fairness when comparing different technologies. It becomes necessary to create a detailed and thorough test for measuring the ability that a watermark has to withstand a set of clearly defined signal operations. In this section these signal operations are presented, and a practical measure for robustness is proposed.

How to Measure

Before defining a metric, it must be stated that one does not need to erase a watermark in order to render it useless. It is said that a watermarking scheme is robust when it is able to withstand a series of attacks that try to degrade the quality of the embedded watermark, up to the point where it is removed, or its recovery process is unsuccessful. This means that just by interfering with the detection process a person can create a successful attack over the system, even unintentionally.

However, in some cases one can overcome this characteristic by using error-correcting codes or a stronger detector (Cox et al., 2002). If an error correction code is applied to the watermark message, then it is unnecessary to entirely recover the watermark W in order to successfully retrieve the embedded message m. The use of stronger detectors can also be very helpful in these situations. For example, if a marking scheme has a publicly available detector, then an attacker will try to tamper with the cover signal up to the point where the detector does not recognize the watermark's presence[14]. Nonetheless, the content owner may have another version of the watermark detector, one that can successfully recover the mark after some extra set of signal processing operations. This "special" detector might not be released for public use for economic, efficiency or security reasons. For example, it might only be used in court cases. The only thing that is really important is that it is possible to design a system with different detector strengths.

Given these two facts, it makes sense to use a metric that allows for different levels of robustness, instead of one that only allows for two different states (the watermark is either robust or not). With this characteristic in mind, the basic procedure for measuring robustness is a three-step process, defined as follows:

1. For each audio file in a determined test set embed a random watermark **W** on the

audio signal A, with the maximum strength possible that does not diminish the fidelity of the cover below a specified minimum (Petitcolas & Anderson, 1999).

2. Apply a set of relevant signal processing operations to the watermarked audio signal **A'.**
3. Finally, for each audio cover, extract the watermark **W** using the corresponding detector and measure the success of the recovery process.

Some of the early literature considered the recovery process successful only if the whole watermark message *m* was recovered (Petitcolas, 2000; Petitcolas & Anderson, 1999). This was in fact a binary robustness metric. However, the use of the *bit-error rate* has become common recently (Gordy & Burton, 2000; Kutter & Hartung, 2000; Kutter & Petitcolas, 2000), as it allows for a more detailed scale of values. The *bit-error rate* (BER) is defined as the ratio of incorrect extracted bits to the total number of embedded bits and can be expressed using the formula:

$$BER = \frac{100}{l}\sum_{n=0}^{l-1}\begin{cases}1, & W'_n = W_n \\ 0, & W'_n \neq W_n\end{cases}$$

where l is the watermark length, W_n corresponds to the n^{th} bit of the embedded watermark and W'_n corresponds to the n^{th} bit of the recovered watermark. In other words, this measure of robustness is the certainty of detection of the embedded mark (Arnold, 2000). It is easy to see why this measure makes more sense, and thus should be used as the metric when evaluating the success of the watermark recovery process and therefore the robustness of an audio watermarking scheme.

A final recommendation must be made at this point. The three-step procedure just described should be repeated several times, since the embedded watermark *W* is randomly generated and the recovery can be successful by chance (Petitcolas, 2000).

Up to this point no details have been given about the signal operations that should be performed in the second step of the robustness test. As a rule of thumb, one should include as a minimum the operations that the audio cover is expected to go through in a real world application. However, this will not provide enough testing, as a malicious attacker will most likely have access to a wide range of tools as well as a broad range of skills. Given this situation, several scenarios should be covered. In the following sections the most common signal operations and attacks that an audio watermark should be able to withstand are presented.

Audio Restoration Attack

Audio restoration techniques have been used for several years now, specifically for restoring old audio recordings that have audible artifacts. In audio restoration the recording is digitized and then analyzed for degradations. After these degradations have been localized, the corresponding samples are eliminated. Finally the recording is reconstructed (that is, the missing samples are recreated) by interpolating the signal using the remaining samples.

One can assume that the audio signal is the product of a stationary autoregressive (AR) process of finite order (Petitcolas & Anderson, 1998). With this assumption in mind, one can use an audio segment to estimate a set of AR parameters and then calculate an approximate value for the missing samples. Both of the estimates are calculated using a least-square minimization technique.

Using the audio restoration method just described one can try to render a watermark undetectable by processing the marked audio signal *A'*. The process is as follows: First divide the audio signal *A'* into *N* blocks of size *m* samples each. A value of *m*=1000 samples has been proposed in the literature (Petitcolas & Anderson, 1999). A block of length *l* is removed from the middle of each block and then restored using the AR audio

restoration algorithm. This generates a reconstructed block also of size *m*. After the *N* blocks have been processed they are concatenated again, and an audio signal *B′* is produced. It is expected that *B′* will be closer to *A* than to *A′* and thus the watermark detector will not find any mark in it.

An error free restoration is theoretically possible in some cases, but this is not desired since it would produce a signal identical to *A′*. What is expected is to create a signal that has an error value big enough to mislead the watermark detector, but small enough to prevent the introduction of audible noise. Adjusting the value of the parameter *l* controls the magnitude of the error (Petitcolas & Anderson, 1999). In particular, a value of *l*=80 samples has proven to give good results.

Invertibility Attack

When resolving ownership cases in court, the disputing parties can both claim that they have inserted a valid watermark on the audio file, as it is sometimes possible to embed multiple marks on a single cover signal. Clearly, one mark must have been embedded before the other.

The ownership is resolved when the parties are asked to show the original work to court. If Alice has the original audio file *A*, which has been kept stored in a safe place, and Mallory has a counterfeit original file $\tilde{A}$, which has been derived from *A*, then Alice can search for her watermark *W* in Mallory's file and will most likely find it. The converse will not happen, and the case will be resolved (Craver et al., 2000). However, an attack to this procedure can be created, and is known as an *invertibility attack*.

Normally the content owner adds a watermark *W* to the audio file *A*, creating a watermarked audio file $A' = A+W$, where the sign "+" denotes the embedding operation. This file is released to the public, while the original *A* and the watermark *W* are stored in a safe place. When a suspicious audio file $\tilde{A}$ appears, the difference $\tilde{W} = \tilde{A} - A$ is computed. This difference should be equal to *W* if *A′* and $\tilde{A}$ are equal, and very close to *W* if $\tilde{A}$ was derived from *A′*. In general, a correlation function $f(W, \tilde{W})$ is used to determine the similarity between the watermark *W* and the extracted data $\tilde{W}$. This function will yield a value close to 1, if *W* and $\tilde{W}$ are similar.

However, Mallory can do the following: she can subtract (rather than add) a second watermark *w* from Alice's watermarked file *A′*, using the inverse of the embedding algorithm. This yields an audio file $\hat{A} = A' - w = A + W - w$, which Mallory can now claim to be the original audio file, along with *w* as the original watermark (Craver, Memon, Yeo, & Yeung, 1998). Now both Alice and Mallory can claim copyright violation from their counterparts.

When the two originals are compared in court, Alice will find that her watermark is present in Mallory's audio file, since $\hat{A} - A = W - w$ is calculated, and $f(W-w, W) \approx 1$. However, Mallory can show that when $A - \hat{A} = w - W$ is calculated, then $f(w-W, w) \approx 1$ as well. In other words, Mallory can show that her mark is also present in Alice's work, even though Alice has kept it locked at all times (Craver, Memon, & Yeung, 1996; Craver, Yeo et al., 1998). Given the symmetry of the equations, it is impossible to decide who is the real owner of the original file. A deadlock is thus created (Craver, Yeo et al., 1998; Pereira et al., 2001).

This attack is a clear example of how one can render a mark unusable without having to remove it, by exploiting the invertibility of the watermarking method, which allows an attacker to remove as well as add watermarks. Such an attack can be prevented by using a non-invertible cryptographic signature in the watermark *W;* that is, using a secure watermarking protocol (Katzenbeisser & Veith, 2002; Voloshynovskiy, Pereira, Pun et al., 2001).

Specific Attack on Echo Watermarking

The echo watermarking technique presented in this chapter can be easily "attacked" simply by detecting the echo and then removing the delayed signal by inverting the convolution formula that was used to embed it. However, the problem consists of detecting the echo without knowing the original signal and the possible delay values. This problem is referred to as *blind echo cancellation*, and is known to be difficult to solve (Petitcolas, Anderson, & G., 1998). Nonetheless, a practical solution to this problem appears to lie in the same function that is used for echo watermarking extraction: *cepstrum autocorrelation*. Cepstrum analysis, along with a brute force search can be used together to find the echo signal in the watermarked audio file A'.

A detailed description of the attack is given by Craver et al. (2000), and the idea is as follows: If we take the power spectrum of $A'(t) = A(t) + \alpha A(t - \Delta t)$, denoted by Φ and then calculate the logarithm of Φ, the amplitude of the delayed signal can be augmented using an autocovariance function[15] over the power spectrum $\Phi'(\ln(\Phi))$. Once the amplitude has been increased, then the "hump" of the signal becomes more visible and the value of the delay Δt can be determined (Petitcolas et al., 1998).

Experiments show that when an artificial echo is added to the signal, this attack works well for values of Δt between 0.5 and three milliseconds (Craver et al., 2000). Given that the watermark is usually embedded with a delay value that ranges from 0.5 to two milliseconds, this attack seems to be well suited for the technique and thus very likely to be successful (Petitcolas et al., 1999).

Collusion Attack

A collusion attack, also known as *averaging*, is especially effective against basic fingerprinting schemes. The basic idea is to take a large number of watermarked copies of the same audio file, and average them in order to produce an audio signal without a detectable mark (Craver et al., 2000; Kirovski & Malvar, 2001).

Another possible scenario is to have copies of multiple works that have been embedded with the same watermark. By averaging the sample values of the audio signals, one could estimate the value of the embedded mark, and then try to subtract it from any of the watermarked works. It has been shown that a small number (around 10) of different copies are needed in order to perform a successful collusion attack (Voloshynovskiy, Pereira, Pun et al., 2001). An obvious countermeasure to this attack is to embed more than one mark on each audio cover, and to make the marks dependant on the characteristics of the audio file itself (Craver et al., 2000).

Signal Diminishment Attacks and Common Processing Operations

Watermarks must be able to survive a series of signal processing operations that are commonly performed on the audio cover work, either intentionally or unintentionally. Any manipulation of an audio signal can result in a successful removal of the embedded mark. Furthermore, the availability of advanced audio editing tools on the Internet, such as Audacity (Dannenberg & Mazzoni, 2002), implies that these operations can be performed without an extensive knowledge of digital signal processing techniques. The removal of a watermark by performing one of these operations is known as a signal diminishment attack, and probably constitutes the most common attack performed on digital watermarks (Meerwald & Pereira, 2002).

Given this, a set of the most common signal operations must be specified, and watermark resistance to these must be evaluated. Even though an audio file will most likely not be subject to all the possible operations, a thorough list is necessary. Defining which subset of these operations

is relevant for a particular watermarking scheme is a task that needs to be done; however, this will be addressed later in the chapter.

The signal processing operations presented here are classified into eight different groups, according to the presentation made in Petitcolas et al. (2001). These are:

- **Dynamics.** These operations change the loudness profile of the audio signal. The most basic way of performing this consists of increasing or decreasing the loudness directly. More complicated operations include limiting, expansion and compression, as they constitute nonlinear operations that are dependant on the audio cover.
- **Filter.** Filters cut off or increase a selected part of the audio spectrum. Equalizers can be seen as filters, as they increase some parts of the spectrum, while decreasing others. More specialized filters include low-pass, high-pass, all-pass, FIR, and so forth.
- **Ambience.** These operations try to simulate the effect of listening to an audio signal in a room. Reverb and delay filters are used for this purpose, as they can be adjusted in order to simulate the different sizes and characteristics that a room can have.
- **Conversion.** Digital audio files are nowadays subject to format changes. For example, old monophonic signals might be converted to stereo format for broadcast transmission. Changes from digital to analog representation and back are also common, and might induce significant quantization noise, as no conversion is perfect.
- **Lossy compression** algorithms are becoming popular, as they reduce the amount of data needed to represent an audio signal. This means that less bandwidth is needed to transmit the signal, and that less space is needed for its storage. These compression algorithms are based on psychoacoustic models and, although different implementations exist, most of them rely on deleting information that is not perceived by the listener. This can pose a serious problem to some watermarking schemes, as they sometimes will hide the watermark exactly in these imperceptible regions. If the watermarking algorithm selects these regions using the same method as the compression algorithm, then one just needs to apply the lossy compression algorithm to the watermarked signal in order to remove the watermark.
- **Noise** can be added in order to remove a watermark. This noise can even be imperceptible, if it is shaped to match the properties of the cover signal. Fragile watermarks are especially vulnerable to this attack. Sometimes noise will appear as the product of other signal operations, rather than intentionally.
- **Modulation** effects like vibrato, chorus, amplitude modulation and flanging are not common post-production operations. However, they are included in most of the audio editing software packages and thus can be easily used in order to remove a watermark.
- **Time stretch** and pitch shift. These operations either change the length of an audio passage without changing its pitch, or change the pitch without changing its length in time. The use of time stretch techniques has become common in radio broadcasts, where stations have been able to increase the number of advertisements without devoting more air time to these (Kuczynski, 2000).
- **Sample permutations.** This group consists of specialized algorithms for audio manipulation, such as the attack on echo hiding just presented. Dropping of some samples in order to misalign the watermark decoder is also a common attack to spread-spectrum watermarking techniques.

It is not always clear how much processing a watermark should be able to withstand. That is, the specific parameters of the diverse filtering operations that can be performed on the cover signal are not easy to determine. In general terms one could expect a marking scheme to be able to survive several processing operations up to the point where they introduce annoying audible effects on the audio work. However, this rule of thumb is still too vague.

Fortunately, guidelines and minimum requirements for audio watermarking schemes have been proposed by different organizations such as the Secure Digital Music Initiative (SDMI), International Federation of the Phonographic Industry (IFPI), and the Japanese Society for Rights of Authors, Composers and Publishers (JASRAC). These guidelines constitute the baseline for any robustness test. In other words, they describe the minimum processing that an audio watermark should be able to resist, regardless of its intended application. Table 4 summarizes these requirements (JASRAC, 2001; SDMI, 2000).

False Positives

When testing for false positives, two different scenarios must be evaluated. The first one occurs when the watermark detector signals the presence of a mark on an unmarked audio file. The second case corresponds to the detector successfully finding a watermark W' on an audio file that has been marked with a watermark W (Cox et al., 2002; Kutter & Hartung, 2000; Petitcolas et al., 2001).

Table 4. Summary of SDMI, STEP and IFPI requirements

The testing procedure for both types of false positives is simple. In the first case one just needs to run the detector on a set of unwatermarked works. For the second case, one can embed a watermark W using a given key K, and then try to extract a different mark W' while using the same key K. The *false positive rate* (FPR) is then defined as the number of successful test runs divided by the total number of test runs. A successful test run is said to occur whenever a false positive is detected.

However, a big problem arises when one takes into account the required false positive rate for some schemes. For example, a popular application such as DVD watermarking requires a false positive rate of 1 in 10^{12} (Cox et al., 2002). In order to verify that this rate is accomplished one would need to run the described experiment during several years. Other applications such as proof of ownership in court are rare, and thus require a lower false positive rate. Nonetheless, a false rate probability of 10^{-6}, required for the mentioned application, can be difficult to test.

MEASURING PERCEPTIBILITY

Digital content consumers are aware of many aspects of emerging watermarking technologies. However, only one prevails over all of them: users are concerned with the appearance of perceptible (audible) artifacts due to the use of a watermarking scheme. Watermarks are supposed to be imperceptible (Cox et al., 2002). Given this fact, one must carefully measure the amount of distortion that the listener will perceive on a watermarked audio file, as compared to its unmarked counterpart. Formal listening tests have been considered the only relevant method for judging audio quality, as traditional objective measures such as the signal-to-noise ratio (SNR) or total-harmonic-distortion[16] (THD) have never been shown to reliably relate to the perceived audio quality, as they can not be used to distinguish inaudible artifacts from audible noise (ITU, 2001; Kutter & Hartung, 2000; Thiede & Kabot, 1996). There is a need to adopt an objective measurement test for perceptibility of audio watermarking schemes.

Furthermore, one must be careful, as perceptibility must not be viewed as a binary condition (Arnold & Schilz, 2002; Cox et al., 2002). Different levels of perceptibility can be achieved by a watermarking scheme; that is, listeners will perceive the presence of the watermark in different ways. Auditory sensitivities vary significantly from individual to individual. As a consequence, any measure of perceptibility that is not binary should accurately reflect the probability of the watermark being detected by a listener.

In this section a practical and automated evaluation of watermark perceptibility is proposed. In order to do so, the human auditory system (HAS) is first described. Then a formal listening test is presented, and finally a psychoacoustical model for automation of such a procedure is outlined.

Human Auditory System (HAS)

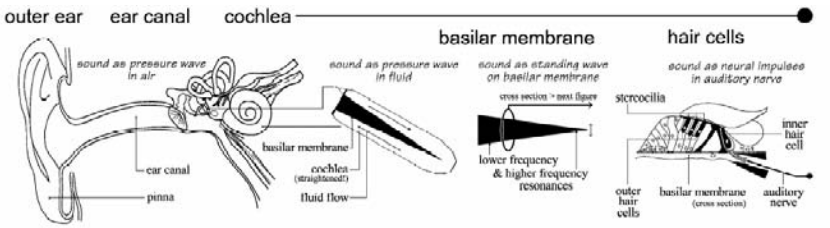
Figure 4, taken from Robinson (2002), presents the physiology of the human auditory system. Each one of its components is now described.

The *pinna* directionally filters incoming sounds, producing a spectral coloration known as *head related transfer function* (or HRTF). This function enables human listeners to localize the sound source in three dimensions.

The *ear canal* filters the sound, attenuating both low and high frequencies. As a result, a resonance arises around 5 kHz. After this, small bones known as the *timpanic membrane* (or ear drum), *malleus* and *incus* transmit the sound pressure wave through the middle ear. The outer and middle ear perform a band pass filter operation on the input signal.

The sound wave arrives at the fluid-filled *cochlea*, a coil within the ear that is partially protected by a bone. Inside the cochlea resides the *basilar membrane* (BM), which semi-divides

Figure 4. Overview of the human auditory system (HAS)



it. The basilar membrane acts as a spectrum analyzer, as it divides the signal into frequency components. Each point on the membrane resonates at a different frequency, and the spacing of these resonant frequencies along the BM is almost logarithmic. The effective frequency selectivity is related to the width of the filter characteristic at each point.

The *outer hair cells*, distributed along the length of the BM, react to feedback from the brainstem. They alter their length to change the resonant properties of the BM. As a consequence, the frequency response of the membrane becomes amplitude dependent.

Finally, the inner hair cells of the basilar membrane fire when the BM moves upward. In doing so, they transduce the sound wave at each point into a signal on the auditory nerve. In this way the signal is half wave rectified. Each cell needs a certain time to recover between successive firings, so the average response during a steady tone is lower than at its onset. This means that the inner hair cells act as an automatic gain control.

The net result of the process described above is that an audio signal, which has a relatively wide-bandwidth, and large dynamic range, is encoded for transmission along the nerves. Each one of these nerves offers a much narrower bandwidth, and limited dynamic range. In addition, a critical process has happened during these steps. Any information that is lost due to the transduction process within the cochlea is not available to the brain. In other words, the cochlea acts as a lossy coder. The vast majority of what we cannot hear is attributable to this transduction process (Robinson & Hawksford, 1999).

Detailed modeling of the components and processes just described will be necessary when creating an auditory model for the evaluation of watermarked audio. In fact, by representing the audio signal at the basilar membrane, one can effectively model what is effectively perceived by a human listener.

Perceptual Phenomena

As was just stated, one can model the processes that take place inside the HAS in order to represent how a listener responds to auditory stimuli. Given its characteristics, the HAS responds differently depending on the frequency and loudness of the input. This means that all components of a watermark may not be equally perceptible. Moreover, it also denotes the need of using a perceptual model to effectively measure the amount of distortion that is imposed on an audio signal when a mark is embedded. Given this fact, in this section the main processes that need to be included on a perceptual model are presented.

Sensitivity refers to the ear's response to direct stimuli. In experiments designed to measure sensitivity, listeners are presented with isolated stimuli and their perception of these stimuli is tested. For example, a common test consists of measuring the minimum sound intensity required to hear a particular frequency (Cox et al., 2002). The main characteristics measured for sensitivity are *frequency* and *loudness.*

The responses of the HAS are frequency dependent; variations in frequency are perceived as different tones. Tests show that the ear is most sensitive to frequencies around 3kHz and that sensitivity declines at very low (20 Hz) and very high (20 kHz) frequencies.

Regarding loudness, different tests have been performed to measure sensitivity. As a general result, one can state that the HAS is able to discern smaller changes when the average intensity is louder. In other words, the human ear is more sensitive to changes in louder signals than in quieter ones.

The second phenomenon that needs to be taken into account is *masking.* A signal that is clearly audible if presented alone can be completely inaudible in the presence of another signal, the masker. This effect is known as masking, and the masked signal is called the *maskee*. For example, a tone might become inaudible in the presence of a second tone at a nearby frequency that is louder. In other words, masking is a measure of a listener's response to one stimulus in the presence of another.

Two different kinds of masking can occur: simultaneous masking and temporal masking (Swanson et al., 1998). In simultaneous masking, both the masker and the maskee are presented at the same time and are quasi-stationary (ITU, 2001). If the masker has a discrete bandwidth, the threshold of hearing is raised even for frequencies below or above the masker. In the situation where a noise-like signal is masking a tonal signal, the amount of masking is almost frequency independent; if the sound pressure of the maskee is about 5 dB below that of the masker, then it becomes inaudible. For other cases, the amount of masking depends on the frequency of the masker.

In temporal masking, the masker and the maskee are presented at different times. Shortly after the decay of a masker, the masked threshold is closer to simultaneous masking of this masker than to the absolute threshold (ITU, 2001). Depending on the duration of the masker, the decay time of the threshold can vary between five ms and 150 ms. Furthermore, weak signals just before loud signals are masked. The duration of this backward masking effect is about five ms.

The third effect that has to be considered is *pooling.* When multiple frequencies are changed rather than just one, it is necessary to know how to combine the sensitivity and masking information for each frequency. Combining the perceptibilities of separate distortions gives a single estimate for the overall change in the work. This is known as pooling. In order to calculate this phenomenon, it is common to apply the formula:

$$D(A, A') = \left(\sum_i | d[i] |^p \right)^{\frac{1}{p}}$$

where d[i] is an estimate of the likelihood that an individual will notice the difference between A and A' in a temporal sample (Cox et al., 2002). In the case of audio, a value of p=1 is sometimes appropriate, which turns the equation into a linear summation.

ABX Listening Test

Audio quality is usually evaluated by performing a listening test. In particular, the ABX listening test is commonly used when evaluating the quality of watermarked signals. Other tests for audio watermark quality evaluation, such as the one described in Arnold and Schilz (2002), follow a similar methodology as well. Given this, it becomes desirable to create an automatic model that predicts the response observed from a human listener in such a procedure.

In an ABX test the listener is presented with three different audio clips: selection A (in this case the non-watermarked audio), selection B (the watermarked audio) and X (either the watermarked or non-watermarked audio), drawn at random. The listener is then asked to decide if selection X is equal to A or B. The number of correct answers is the basis to decide if the watermarked audio is perceptually different than the original audio

and one will, therefore, declare the watermarking algorithm as "perceptible". In the other case, if the watermarked audio is perceptually equal to the original audio, the watermarking algorithm will be declared as *transparent*, or imperceptible. In the particular case of Arnold and Schilz (2002), the level of transparency is assumed to be determined by the noise-to-mask ratio (NMR).

The ABX test is fully described in ITU Recommendation ITU-R BS.1116, and has been successfully used for subjective measurement of impaired audio signals. Normally only one attribute is used for quality evaluation. It is also defined that this attribute represents any and all detected differences between the original signal and the signal under test. It is known as *basic audio quality* (BAQ), and is calculated as the difference between the grade given to the impaired signal and the grade given to the original signal. Each one of these grades uses the five-level impairment scale that was presented previously. Given this fact, values for the BAQ range between 0 and -4, where 0 corresponds to an imperceptible impairment and -4 to one judged as very annoying.

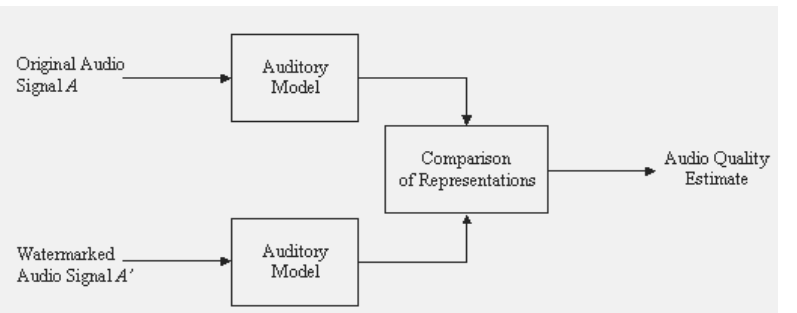
Although its results are highly reliable, there are many problems related to performing an ABX test for watermark quality evaluation. One of them is the subjective nature of the test, as the perception conditions of the listener may vary with time. Another problem arises from the high costs associated with the test. These costs include the setup of audio equipment[17], construction of a noise-free listening room, and the costs of employing individuals with extraordinarily acute hearing. Finally, the time required to perform extensive testing also poses a problem to this alternative.

Given these facts it becomes desirable to automate the ABX listening test, and incorporate it into a perceptual model of the HAS. If this is implemented, then the task measuring perceptibility can be fully automated and thus watermarking schemes can be effectively and thoroughly evaluated. Fortunately, several perceptual models for audio processing have been proposed. Specifically, in the field of audio coding, psychoacoustic models have been successfully implemented to evaluate the perceptual quality of coded audio. These models can be used as a baseline performance tool for measuring the perceptibility of audio watermarking schemes; thus they are now presented.

A Perceptual Model

A perceptual model used for evaluation of watermarked content must compare the quality of two different audio signals in a way that is similar to the ABX listening test. These two signals correspond to the original audio cover *A* and the watermarked audio file *A'*. An ideal system will receive both signals as an input, process them through an auditory model, and compare the representations given by this model (Thiede et al., 1998). Finally it will return a score for the watermarked file *A'*

Figure 5. Architecture of a perceptual measurement system



in the five-level impairment scale. More importantly, the results of such an objective test must be highly correlated with those achieved under a subjective listening test (ITU, 2001). The general architecture of such a perceptual measurement system is depicted in Figure 5.

The auditory model used to process the input signals will have a similar structure to that of the HAS. In general terms, the response of each one of the components of the HAS is modeled by a series of filters. In particular, a synopsis of the models proposed in Robinson and Hawksford (1999), Thiede and Kabot (1996), Thiede et al. (1998), and ITU (2001) is now presented.

The filtering performed by the pinna and ear canal is simulated by an FIR filter, which has been derived from experiments with a dummy head. More realistic approaches can use measurements from human subjects.

After this prefiltering, the audio signal has to be converted to a basilar membrane representation. That is, the amplitude dependent response of the basilar membrane needs to be simulated. In order to do this, the first step consists of processing the input signal through a bank of amplitude dependant filters, each one adapted to the frequency response of a point on the basilar membrane. The center frequency of each filter should be linearly spaced on the Bark scale, a commonly used frequency scale[18]. The actual number of filters to be used depends on the particular implementation. Other approaches might use a fast Fourier transform to decompose the signal, but this creates a trade-off between temporal and spectral resolution (Thiede & Kabot, 1996).

At each point in the basilar membrane, its movement is transduced into an electrical signal by the hair cells. The firing of individual cells is pseudorandom, but when the individual signals are combined, the proper motion of the BM is derived. Simulating the individual response of each hair cell and combining these responses is a difficult task, so other practical solutions have to be applied. In particular, Robinson and Hawksford (1999) implement a solution based on calculating the half wave response of the cells, and then using a series of feedback loops to simulate the increased sensitivity of the inner hair cells to the onset of sounds. Other schemes might just convolve the signal with a spreading function, to simulate the dispersion of energy along the basilar membrane, and then convert the signal back to decibels (ITU, 2001). Independently of the method used, the basilar membrane representation is obtained at this point.

After a basilar membrane representation has been obtained for both the original audio signal *A*, and the watermarked audio signal *A'*, the perceived difference between the two has to be calculated. The difference between the signals at each frequency band has to be calculated, and then it must be determined at what level these differences will become audible for a human listener (Robinson & Hawksford, 1999). In the case of the ITU Recommendation ITU-R BS.1387, this task is done by calculating a series of model variables, such as excitation, modulation and loudness patterns, and using them as an input to an artificial neural network with one hidden layer (ITU, 2001). In the model proposed in Robinson and Hawksford (1999), this is done as a summation over time (over an interval of 20 ms) along with weighting of the signal and peak suppression.

The result of this process is an objective difference between the two signals. In the case of the ITU model, the result is given in a negative five-level impairment scale, just like the BAQ, and is known as the *objective difference grade* (ODG). For other models, the difference is given in implementation-dependant units. In both cases, a mapping or scaling function, from the model units to the ITU-R. 500 scale, must be used.

For the ITU model, this mapping could be trivial, as all that is needed is to add a value of five to the value of the ODG. However, a more precise mapping function could be developed. The ODG has a resolution of one decimal, and the model was not specifically designed for the evaluation

watermarking schemes. Given this, a nonlinear mapping (for example using a logarithmic function) could be more appropriate.

For other systems, determining such a function will depend on the particular implementation of the auditory model; nonetheless such a function should exist, as a correlation between objective and subjective measures was stated as an initial requirement. For example, in the case of Thiede and Kabot (1996), a sigmoidal mapping function is used. Furthermore, the parameters for the mapping function can be calculated using a control group consisting of widely available listening test data.

The resulting grade, in the five-level scale, is defined as the perceptibility of the audio watermark. This means that in order to estimate the perceptibility of the watermarking scheme, several test runs must be performed. Again, these test runs should embed a random mark on a cover signal, and a large and representative set of audio cover signals must be used. The perceptibility test score is finally calculated by averaging the different results obtained for each one of the individual tests.

FINAL BENCHMARK SCORE

In the previous sections, three different testing procedures have been proposed, in order to measure the fidelity, robustness and perceptibility of a watermarking scheme. Each one of these tests has resulted in several scores, some of which may be more useful than others. In this section, these scores are combined in order to obtain a final benchmarking score. As a result, fair comparison amongst competing technologies is possible, as the final watermarking scheme evaluation score is obtained.

In addition, another issue is addressed at this point: defining the specific parameters to be used for each attack while performing the robustness test. While the different attacks were explained in the sixth section, the strength at which they should be applied was not specified. As a general rule of thumb, it was just stated that these operations should be tested up to the point where noticeable distortion is introduced on the audio cover file.

As it has been previously discussed, addressing these two topics can prove to be a difficult task. Moreover, a single answer might not be appropriate for every possible watermarking application. Given this fact, one should develop and use a set of application-specific evaluation templates to overcome this restriction. In order to do so, an *evaluation template* is defined as a set of guidelines that specifies the specific parameters to be used for the different tests performed, and also denotes the relative importance of each one of the tests performed on the watermarking scheme. Two fundamental concepts have been incorporated into that of evaluation templates: evaluation profiles and application specific benchmarking.

Evaluation profiles have been proposed in Petitcolas (2000) as a method for testing different levels of robustness. Their sole purpose is to establish the set of tests and media to be used when evaluating a marking algorithm. For example, Table 4, which summarizes the robustness requirements imposed by various organizations, constitutes a general-purpose evaluation profile. More specific profiles have to be developed when evaluating more specific watermarking systems. For example, one should test a marking scheme intended for advertisement broadcast monitoring with a set of recordings similar to those that will be used in a real world situation. There is no point in testing such an algorithm with a set of high-fidelity musical recordings. Evaluation profiles are thus a part of the proposed evaluation templates.

Application specific benchmarking, in turn, is proposed in Pereira et al. (2001) and Voloshynovskiy, Pereira, Iquise and Pun (2001) and consists of averaging the results of the different tests performed to a marking scheme, using a set of weights that is specific to the intended application of the watermarking algorithm. In

other words, attacks are weighted as a function of applications (Pereira et al., 2001). In the specific case of the evaluation templates proposed in this document, two different sets of weights should be specified: those used when measuring one of the three fundamental characteristics of the algorithm (i.e., fidelity, robustness and perceptibility); and those used when combining these measures into a single benchmarking score.

After the different weights have been established, the *overall watermarking scheme score* is calculated as a simple weighted average, with the formula:

$$Score = w_f * s_f + w_r * s_r + w_p * s_p$$

where *w* represents the assigned weight for a test, *s* to the score received on a test, and the subscripts *f, r, p* denote the fidelity, robustness and perceptibility tests respectively. In turn, the values of s_f, s_r, and s_p are also determined using a weighted average for the different measures obtained on the specific subtests.

The use of an evaluation template is a simple, yet powerful idea. It allows for a fair comparison of watermarking schemes, and for ease of automated testing. After these templates have been defined, one needs only to select the intended application of the watermarking scheme that is to be evaluated, and the rest of the operations can be performed automatically. Nonetheless, time has to be devoted to the task of carefully defining the set of evaluation templates for the different applications sought to be tested. A very simple, general-purpose evaluation template is shown in Box 1, as an example.

Presenting the Results

The main result of the benchmark presented here is the overall watermarking scheme score that has just been explained. It corresponds to a single, numerical result. As a consequence, comparison between similar schemes is both quick and easy. Having such a comprehensive quality measure is sufficient in most cases.

Under some circumstances the intermediate scores might also be important, as one might want to know more about the particular characteristics of a watermarking algorithm, rather than compare it against others in a general way. For example, one might just be interested in the perceptibility score of the echo watermarking algorithm, or in the robustness against uniform noise for two different schemes. For these cases, the use of graphs, as proposed in Kutter and Hartung (2000) and Kutter and Petitcolas (1999, 2000) is recommended.

The graphs should plot the variance in two different parameters, with the remaining parameters fixed. That is, the test setup conditions should remain constant along different test runs. Finally, several test runs should be performed, and the results averaged. As a consequence, a set of variable and fixed parameters for performing the comparisons are possible, and thus several graphs can be plotted. Some of the most useful graphs, based on the discussion presented in Kutter and Petitcolas (1999), along with their corresponding variables and constants, are summarized in Table 5.

Of special interest to some watermark developers is the use of receiver operating characteristic (ROC) graphs, as they show the relation between false positives and false negatives for a given watermarking system. "They are useful for assessing the overall behavior and reliability of the watermarking scheme being tested" (Petitcolas & Anderson, 1999).

In order to understand ROC graphs, one should remember that a watermark decoder can be viewed as a system that performs two different steps: first it decides if a watermark is present on the audio signal *A'*, and then it tries to recover the embedded watermark *W*. The first step can be viewed as a form of hypothesis testing (Kutter & Hartung, 2000), where the decoder decides between the alternative hypothesis (a watermark is present),

Box 1. Evaluation template

Application:

General Purpose Audio Watermarking

Final Score Weights:

Fidelity = 1/3, Robustness = 1/3, Perceptibility = 1/3

FIDELITY TEST

Measure	Parameters	Weight
Quality	N/A	0.75
Data Payload	Watermark length = 100 bits, score calculated as BER.	0.125
Speed	Watermark length = 50 bits, score calculated as 1 if embedding time is less than 2 minutes, 0 otherwise.	0.125

ROBUSTNESS TEST

Measure	Parameters	Weight
D/A Conversion	D/A ↔ A/D twice.	1/14
Equalization	10 band graphic equalizer with the following characteristics:	1/14
Band-pass filtering	100 Hz – 6 kHz, 12dB/oct.	1/14
Time stretch and pitch change	+/- 10% compression and decompression	1/14
Codecs	AAC, MPEG-4 AAC with perceptual noise substitution, MPEG-1 Audio Layer 3, Windows Media Audio, and Twin-VQ at 128 kbps.	1/14
Noise addition	Adding white noise with constant level of 40dB lower than total averaged music power (SNR: 40dB)	1/14
Time scale modification	Pitch invariant time scaling of +/- 4%	1/14
Wow and flutter	0.5% rms, from DC to 250Hz	1/14
Echo addition	Delay = 100 milliseconds, feedback coefficient = 0.5	1/14
Down mixing	Stereo to mono, and Dolby surround	1/14
Sample rate conversion	44.1 kHz to 16 kHz	1/14
Dynamic range reduction	Threshold of 50dB, 16dB maximum compression Rate: 10 millisecond attack, 3 second recovery	1/14
Amplitude compression	16 bits to 8 bits	1/14

Freq. (Hz)	31	62	125	250	500	1k	2k	4k	8k	16k
Gain (db)	-6	+6	-6	+3	-6	+6	-6	+6	-6	+6

PERCEPTIBILITY TEST

Watermark perceptibility	N/A	1

Table 5. Useful graphs when evaluating a specific watermarking scheme

Graph Type	Perceptual Quality	Robustness Measure	Strength of a Specific Attack	Data Payload
Robustness to an Attack	fixed	variable	variable	fixed
Perceptual Quality vs. Payload	variable	fixed	fixed	variable
Attack Strength vs. Perceptual Quality	variable	fixed	variable	fixed
ROC	fixed	fixed	fixed/variable	fixed

and the null hypothesis (the watermark is not present). Given these two options, two different errors can occur, as was stated in the third section: a false positive, and a false negative.

ROC graphs plot the true positive fraction (TPF) on the Y-axis, and the false positive fraction (FPF) on the X-axis. The TPF is defined by the formula:

$$TPF = \frac{TP}{TP + FN}$$

where *TP* is the number of true positive test results, and *FN* is the number of false negative tests. Conversely, the FPF is defined by:

$$FPF = \frac{FP}{TN + FP}$$

where *TN* is the number of false-positive results, and *FP* the number of true negative results. An optimal detector will have a curve that goes from the bottom left corner to the top left, and then to the top right corner (Kutter & Petitcolas, 2000). Finally, it must be stated that the same number of watermarked and unwatermarked audio samples should be used for the test, although false-positive testing can be time-consuming, as was previously discussed in this document.

Automated Evaluation

The watermarking benchmark proposed here can be implemented for the automated evaluation of different watermarking schemes. In fact, this idea has been included in test design, and has motivated some key decisions, such as the use of a computational model of the ear instead of a formal listening test. Moreover, the establishment of an automated test for watermarking systems is an industry need. This assertion is derived from the following fact: to evaluate the quality of a watermarking scheme one can do one of the following three options (Petitcolas, 2000):

- Trust the watermark developer and his or her claims about watermark performance.
- Thoroughly test the scheme oneself.
- Have the watermarking scheme evaluated by a trusted third party.

Only the third option provides an objective solution to this problem, as long as the evaluation methodology and results are transparent to the public (Petitcolas et al., 2001). This means that anybody should be able to reproduce the results easily. As a conclusion, the industry needs to establish a trusted evaluation authority in order to objectively evaluate its watermarking products. The establishment of watermark certification programs has been proposed, and projects such as the Certimark and StirMark benchmarks are

under development (Certimark, 2001; Kutter & Petitcolas, 2000; Pereira et al., 2001; Petitcolas et al., 2001). However, these programs seem to be aimed mainly at testing of image watermarking systems (Meerwald & Pereira, 2002). A similar initiative for audio watermark testing has yet to be proposed.

Nonetheless, one problem remains unsolved: watermarking scheme developers may not be willing to give the source code for their embedding and recovery systems to a testing authority. If this is the situation, then both watermark embedding and recovery processes must be performed at the developer's side, while the rest of the operations can be performed by the watermark tester. The problem with this scheme is that the watermark developer could cheat and always report the watermark as being recovered by the detector. Even if a basic zero knowledge protocol is used in the testing procedure, the developer can cheat, as he or she will have access to both the original audio file A and the modified, watermarked file $\tilde{A}$ that has been previously processed by the tester. The cheat is possible because the developer can estimate the value of the watermarked file A', even if it has always been kept secured by the tester (Petitcolas, 2000), and then try to extract the mark from this estimated signal. Given this fact, one partial solution consists of giving the watermark decoder to the evaluator, while the developer maintains control over the watermark embedder, or vice versa[19].

Hopefully, as the need for thorough testing of watermarking systems increases, watermark developers will be more willing to give out access to their systems for thorough evaluation. Furthermore, if a common testing interface is agreed upon by watermark developers, then they will not need to release the source code for their products; a compiled library will be enough for practical testing of the implemented scheme if it follows a previously defined set of design guidelines. Nonetheless, it is uncertain if both the watermarking industry and community will undergo such an effort.

CONCLUSION

Digital watermarking schemes can prove to be a valuable technique for copyright control of digital material. Different applications and properties of digital watermarks have been reviewed in this chapter, specifically as they apply to digital audio. However, a problem arises as different claims are made about the quality of the watermarking schemes being developed; every developer measures the quality of their respective schemes using a different set of procedures and metrics, making it impossible to perform objective comparisons among their products.

As the problem just described can affect the credibility of watermarking system developers, as well as the acceptance of this emerging technology by content owners, this document has presented a practical test for measuring the quality of digital audio watermarking techniques. The implementation and further development of such a test can prove to be beneficial not only to the industry, but also to the growing field of researchers currently working on the subject.

Nonetheless, several problems arise while implementing a widely accepted benchmark for watermarking schemes. Most of these problems have been presented in this document, but others have not been thoroughly discussed. One of these problems consists of including the growing number of attacks against marking systems that are proposed every year. These attacks get more complex and thus their implementation becomes more difficult (Meerwald & Pereira, 2002; Voloshynovskiy, Pereira, Pun et al., 2001); nonetheless, they need to be implemented and included if real world testing is sought.

Another problem arises when other aspects of the systems are to be evaluated. For example, user interfaces can be very important in determining whether a watermarking product will be widely accepted (Craver et al., 2000). Its evaluation is not directly related to the architecture and performance of a marking system, but it certainly will have an impact on its acceptance.

Legal constraints can also affect watermark testing, as patents might protect some of the techniques used for watermark evaluation. In other situations, the use of certain watermarking schemes in court as acceptable proofs of ownership cannot be guaranteed, and a case-by-case study must be performed (Craver, Yeo et al., 1998; Lai & Buonaiuti, 2000). Such legal attacks depend on many factors, such as the economic power of the disputing parties.

While these difficulties are important, they should not be considered severe and must not undermine the importance of implementing a widely accepted benchmarking for audio watermarking systems. Instead, they show the need for further development of the current testing techniques. The industry has seen that ambiguous requirements and unmethodical testing can prove to be a disaster, as they can lead to the development of unreliable systems (Craver et al., 2001).

Finally, the importance of a specific benchmark for audio watermarking must be stated. Most of the available literature on watermarking relates to the specific field of image watermarking. In a similar way, the development of testing techniques for watermarking has focused on the marking of digital images. Benchmarks currently being developed, such as Stirmark and Certimark, will be extended in the future to manage digital audio content (Certimark, 2001; Kutter & Petitcolas, 2000); however, this might not be an easy task, as the metrics used in these benchmarks have been optimized for the evaluation of image watermarking techniques. It is in this aspect that the test proposed in this document proves to be valuable, as it proposes the use of a psychoacoustical model in order to measure the perceptual quality of audio watermarking schemes. Other aspects, such as the use of a communications model as the base for the test design, are novel as well, and hopefully will be incorporated into the watermark benchmarking initiatives currently under development.

ENDNOTES

1 It must be stated that when information is digital there is no difference between an original and a bit by bit copy. This constitutes the core of the threat to art works, such as music recordings, as any copy has the same quality as the original. This problem did not exist with technologies such as cassette recorders, since the fidelity of a second-generation copy was not high enough to consider the technology a threat.

2 A test subject is defined as a specific implementation of a watermarking algorithm, based on one of the general techniques presented in this document.

3 It is implied that the transmission of a watermark is considered a communication process, where the content creator embeds a watermark into a work, which acts as a channel. The watermark is meant to be recovered later by a receiver, but there is no guarantee that the recovery will be successful, as the channel is prone to some tampering. This assumption will be further explained later in the document.

[4] Or a copy of such, given the digital nature of the medium.

[5] A cover is the same thing as a work. C, the set of all possible covers (or all possible works), is known as content.

[6] This pattern is also known as a pseudo-noise (PN) sequence. Even though the watermark message and the PN-sequence are different, it is the latter one we refer to as the watermark W.

[7] The fingerprinting mechanism implemented by the DiVX, where each player had an embedder rather than a decoder, constitutes an interesting and uncommon case.

[8] This in accordance to Kerckhoff's principle.

[9] In the case of an audio recording, the symbol ℗ along with the owner name must be printed on the surface of the physical media.

[10] The registration fee at the Office of Copyrights and Patents can be found online at: http://www.loc.gov/copyright.

[11] In fact, the call for proposal for Phase II of SDMI requires this functionality (Initiative, 2000).

[12] This is very similar to the use of serial numbers in software packages.

[13] Some of the literature refers to this distortion as beating.

[14] This is known as an oracle attack.

[15] $C(x) = E\left((x-\overline{x})(x-\overline{x})^{*}\right)$

[16] THD is the amount of undesirable harmonics present in an output audio signal, expressed as a percentage. The lower the percentage the better.

[17] A description of the equipment used on a formal listening test can be found in Arnold and Schilz (2002).

[18] 1 Bark corresponds to 100 Hz, and 24 Bark correspond to 15000 Hz.

[19] This decision will be motivated by the economics of the system; that is, by what part of the systems is considered more valuable by the developer.

Chapter 3.12
Digital Watermarking for Multimedia Transaction Tracking

Dan Yu
Nanyang Technological University, Singapore

Farook Sattar
Nanyang Technological University, Singapore

ABSTRACT

This chapter focuses on the issue of transaction tracking in multimedia distribution applications through digital watermarking terminology. The existing watermarking schemes are summarized and their assumptions as well as the limitations for tracking are analyzed. In particular, an Independent Component Analysis (ICA)-based watermarking scheme is proposed, which can overcome the problems of the existing watermarking schemes. Multiple watermarking technique is exploited—one watermark to identify the rightful owner of the work and the other one to identify the legal user of a copy of the work. In the absence of original data, watermark, embedding locations and strengths, the ICA-based watermarking scheme is introduced for efficient watermark extraction with some side information. The robustness of the proposed scheme against some common signal-processing attacks as well as the related future work are also presented. Finally, some challenging issues in multimedia transaction tracking through digital watermarking are discussed.

INTRODUCTION

We are now in a digital information age. Digital information technology has changed our society as well as our lives. The information revolution takes place in the following two forms

- Data/information retrieval/representation
- Data/information dissemination/communication

Digital presentation of data allows information recorded in a digital format, and thus, it brings easy access to generate and replicate the information. It is such an easy access that provides the novelty

in the current phase of the information revolution. Digital technology allows primarily use with the new physical communications media, such as satellite and fiber-optic transmission. Therefore, PCs, e-mail, MPCs, LANs, WANs, MANs, intranets, and the Internet have been evolving rapidly since the 1980s. The Internet has a worldwide broadcasting capability, a mechanism for information distribution, and a medium for collaboration and interaction between individuals and their computers regardless of geographic location. This allows researchers and professionals to share relevant data and information with each other.

As image, audio, video, and other works become available in digital form, perfect copies can be easily made. The widespread use of computer networks and the global reach of the World Wide Web have added substantially an astonishing abundance of information in digital form, as well as offering unprecedented ease of access to it. Creating, publishing, distributing, using, and reusing information have become many times easier and faster in the past decade. The good news is the enrichment that this explosive growth in information brings to society as a whole. The bad news is that it can also bring to those who take advantage of the properties of digital information and the Web to copy, distribute, and use information illegally. The Web is an information resource of extraordinary size and depth, yet it is also an information reproduction and dissemination facility of great demand and capability. Therefore, there is currently a significant amount of research in intellectual property protection issues involving multimedia content distribution via the Internet.

Thus the objective of this chapter is to present multimedia transaction tracking through digital watermarking terminology. The Independent Component Analysis (ICA) technique is employed efficiently for watermark extraction in order to verify the recipient of the distributed content, and hence, to trace illegal transaction of the work to be protected.

MULTIMEDIA DISTRIBUTION FRAMEWORK THROUGH DIGITAL WATERMARKING

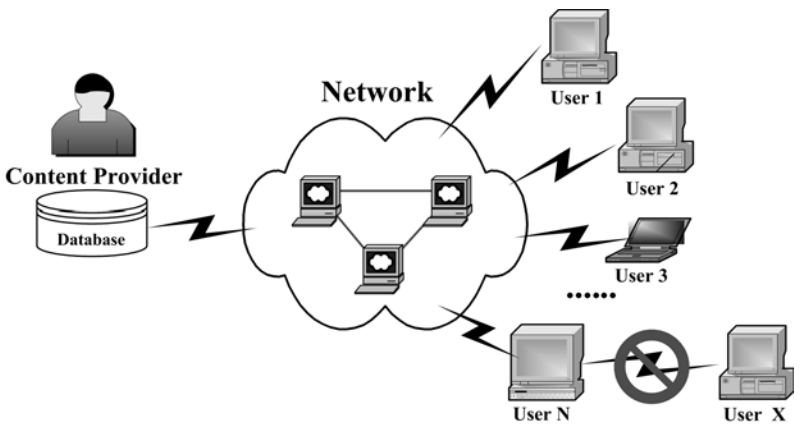
The rapid growth of networked multimedia systems has increased the need for the protection and enforcement of intellectual property (IP) rights of digital media. IP protection is becoming increasingly important nowadays. The tasks to achieve IP protection for multimedia distribution on the Internet can be classified as follows:

- **Ownership identification**: The owner of the original work must be able to provide the trustful proof that he/she is the rightful owner of the content.
- **Transaction tracking**: The owner must be able to track the distributions of the work, so that he/she is able to find the person who is responsible for the illegal replication and redistribution.
- **Content authentication**: The owner should be able to detect any illegal attempts to alter the work.

This chapter concentrates on the task of transaction tracking for multimedia distribution applications. Let us consider the scenario when an owner wants to sell or distribute the work to registered users only. To enforce IP rights, two primary problems have to be solved. First of all, the owner must be able to prove that he/she is the legal owner of the distributed content. Second, if the data have been subsequently copied and redistributed illegally, the owner must be able to find the person who is responsible for the illegal copying and redistribution of the data (see Figure 1).

The first technology adopted to enforce protection of IP rights is cryptography. Cryptographic technology (Schneier, 1995) provides an effective tool to secure the distribution process and control the legal uses of the contents that have been received by a user. The contents to be delivered

Figure 1. A multimedia distribution system where the digital content could be illegally redistributed to an illegal user



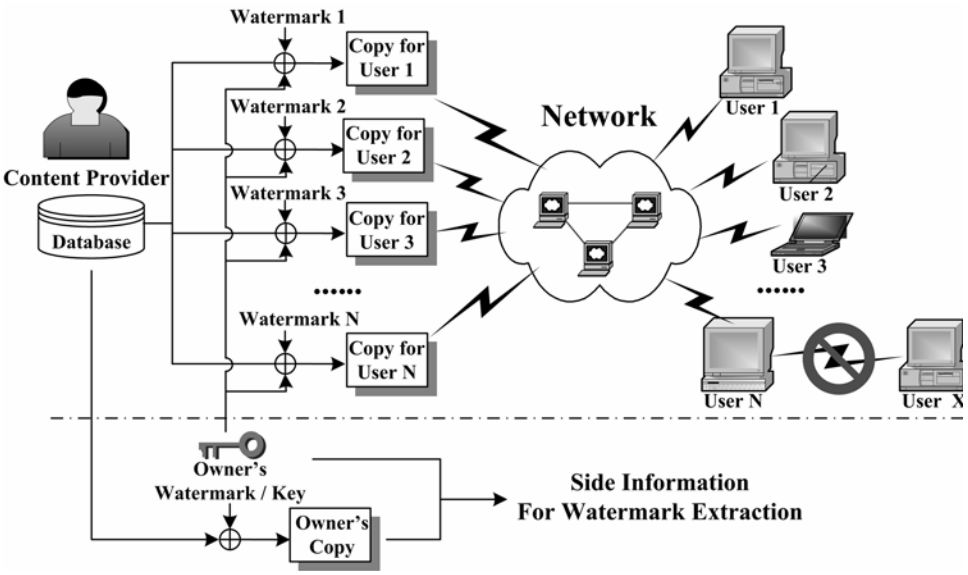
over the Internet are encrypted, and only legal users who hold the decryption key are able to use the encrypted data, whereas the data stream would be useless to a pirate without the appropriate decryption key. However, for an error-free transmission through a network, the contents after the decryption in the cryptography will be exactly the same as the original data. The data contents can be replicated perfectly many times and the user can also manipulate the contents.

Researchers and scientists are then turned to search for other technologies to counter copyright piracy on global networks that are not solvable by cryptography. In this context, recently digital watermarking technology (Cox, Miller, & Bloom, 2002) has drawn much attention. In digital watermarking, the information is transparently embedded into the work, rather than a specific media format, such as the header of a file that could be lost during transmission or file format transformation. Digital watermarking technique thus provides an efficient means for transaction tracking of illegal copying as well as redistribution of multimedia information. For a typical transaction-tracking application, the watermark identifies the first legal recipient of the work. If it is subsequently found that the work has been illegally redistributed, the watermark can then help to identify the person who is responsible for it.

Figure 2 presents a multimedia distribution framework to enforce IP rights through a technique of multiple watermarking. Multiple watermarking (Lu & Mark, 2001; Mintzer & Braudaway, 1999; Sheppard, Safavi-Naini, & Ogunbona, 2001), as suggested by the name, refers to embedding different types of watermarks into single multimedia content to accomplish different goals. For example, one of the watermarks could be used to verify ownership, the second one is to identify the recipient, and the third one is to authenticate content integrity.

For the Internet distribution application, the users first send a request to the content provider whenever they are interested for the multimedia contents. The owner can then distribute the work by signing a watermark to a registered user to uniquely identify the recipient of the work, as shown in Figure 2. All data sent to a registered user are embedded with an assigned watermark as well as the owner's watermark, while maintaining a good perceptual visual quality of the marked content. In this presented framework, the IP rights of the distributed works are enforced from the two following aspects by employing a multiple watermarking technique:

Figure 2. The multimedia distribution framework by inserting an owner's watermark to identify the ownership of the work and a unique user's watermark to identify each unique legal user



- Every copy of the work contains the owner's watermark to identify the rightful ownership of the work.
- The owner or an authorized representative can uniquely identify the recipient or the legal user of a particular copy of the multimedia content according to the embedded user's unique watermark.

Consider the case when the owner needs to prove the rightful ownership of the content. The owner can present his/her original data (without any marks) of the work as well as his/her watermark as evidence. The two embedded watermarks, including one owner's watermark and one user's watermark, are therefore able to extract by a simple subtraction method (Cox, Miller, & Bloom, 2002; Cox, Leighton, & Shamoon, 1997). One extracted watermark, that is, the owner's watermark, is matched with the previously presented owner's watermark. The rightful ownership of the content is thus verified. It is an essential prerequisite for IP protection to embed the owner's watermark into every copy of the work to be distributed over the Internet. The more difficult and challenging task, as discussed in this chapter, is to identify the legal users efficiently in the absence of the original data, and hence to trace the transactions of a particular copy of the multimedia content. For the purpose of security in multimedia, the original data are always kept in secret and should not be known to the public during watermark extraction. In some real applications, the owner needs the authorized representatives or service providers to perform the transaction-tracking tasks. For security reasons, the owner also cannot provide the original data to those representatives. Therefore, there arises a challenging issue how to extract the user's watermark in the absence of the original data. This is the main problem in transaction tracking through digital watermarking, which has been discussed in this chapter.

THE LIMITATIONS OF THE CURRENT WATERMARKING SCHEMES AND SOLUTIONS

A wide range of watermarking algorithms has been proposed. In terms of various applications, the watermarking techniques can be classified into two categories:

1. **Robust copyright marking**: to provide evidence for proving the rightful ownership of the protected digital media
2. **Authenticate marking**: to authenticate any possible alteration in the protected digital media

Robust marks can verify the ownership of the digital data, whereas the authenticate marks are used to prove whether an object has been "touched" or manipulated. This chapter focuses on robust watermarking. Robust watermarking, as opposed to authentication marking, requires the embedded watermark to be robust against all types of attacks so that it should be able to survive against attacks before the quality of the watermarked image is drastically degraded.

The major research studies on current robust watermarking techniques include the following key technical points (Barni, Bartolini, Cappellini, & Piva, 1998; Cox et al., 1997; Delaigle, Vleeschouwer, & Macq, 1998; Hartung & Kutter, 1999; Katzenbeisser & Petitcolas, 2000; Nikolaidis, & Pitas, 1998; Parhi & Nishitani, 1999):

- The choice of a work space to perform the hiding operation, mainly a spatial domain (Nikolaidis & Pitas, 1998), or a transform domain such as full-frame Discrete Cosine Transform (full DCT) (Barni et al., 1998; Cox et al., 1997; Piva, Barni, Bartoloni, & Cappellini, 1997), block DCT (Benham, Memon, Yeo, & Yeung, 1997; Hartung & Girod, 1996; Koch & Zhao, 1995; Langelaar, Lubbe, & Lagendijk, 1997; Podilchuk & Zeng, 1997; Xia, Boncelet, & Arce, 1997), Fourier Transform (FT) (Ruanaidh, Dowling, & Boland, 1996), Mellin-Fourier (Ruanaidh & Pun, 1997, 1998), or wavelet (Dugad, Ratakonda, & Ahuja, 1998; Inoue, Miyazaki, Yamamoto, & Katsura, 1998; Kundur & Hatzinakos, 1998; Wang, Su, & Kuo, 1998; Xie & Arce, 1998)
- The study of optimal watermark embedding locations based on the human visual system (Delaigle et al., 1998; Kankanhalli, Rajmohan, & Ramakrishnan, 1998; Liu, Kong, Kong, & Liu, 2001; Voloshynovskiy, Herrigel, Baumgaertner, & Pun, 1999)
- The signal embedding techniques by addition, signal-adaptive addition, or modulation methods (Cox et al., 1997; Piva et al., 1997)
- The watermark detection and extraction algorithms either in blind (Piva et al., 1997) or nonblind manner (Cox et al., 1997)

Watermark recovery is usually more robust if its original, unwatermarked data are available. For example, a simple subtraction method (Cox et al., 1997) is used for watermark extraction at the locations where watermark is embedded. The presence of the watermark is determined by cross-correlation of the original and the recovered watermark. In Piva, Barni, Bartolini, and Cappellini's method (1997), the selected DCT coefficients, where the watermark is embedded, are directly matched with all the possible watermarks stored in the database. As a result, the original data are not required for watermark detection. However, a predefined threshold is still needed to determine the presence of the watermark.

From the viewpoint of the presence of a given watermark at the extraction or verification stage, there are two different types of watermarking systems found in the literature (Katzenbeisser & Petitcolas, 2000). The first type is to embed a specific watermark or information. Most watermarking techniques for copyright protection

belong to this watermarking category, where it is assumed that the embedded watermark is previously known. The objective of this type of watermarking scheme is to verify the existence of the previously known watermark with or without the help of this watermark. The second type refers to embedding arbitrary information, which is, for example, useful for tracking the unique receipt of a copy of the distributed data. In such scenario, the watermark embedded in an image copy is previously unknown, therefore, no prior information regarding embedded watermark is available for watermark extraction. It makes the transaction tracking more difficult.

Assumptions as well as limitations for most of the existing watermarking schemes that can cause difficulties and ineffectiveness to apply in multimedia transaction tracking are summarized in the following:

(a) In some watermarking algorithms, watermark detection and extraction requires the presence of the original content. This is not desirable since the original data should always be kept secret and should not be shown to the public, or sometimes the original data are even not available immediately. Therefore, blind watermarking techniques are of great interest and concern nowadays.
(b) Most of the existing watermarking schemes (Cox et al., 1997; Cox et al., 2002; Katzenbeisser & Petitcolas, 2000) are based on some assumptions about watermark detection and extraction, such as the previous knowledge of watermark locations, strengths, or some threshold. However, in order to ensure the robustness and invisibility of the watermark, the optimum embedding locations as well as the embedding strengths are generally different for different images. For a large image database, it could be a disadvantage if it requires watermark locations and strengths information for detection and extraction of the watermark. As a result, a large amount of side information needs to be stored.
(c) As explained previously, Figure 2 shows a framework to prevent illegal redistribution of the data by a legal user. In such scenario, the current watermark detection and extraction algorithms requiring information of the watermark locations and strengths, or even the original watermark, could fail because no one knows which watermark exists in the received copy of the work.
(d) Moreover, the general watermark detection algorithm is based on a match filter finding the maximum correlation of the recovered watermark with the stored watermarks in the database containing the watermarks used to identify all possible users. It is a rather time-consuming and inefficient process, especially when a large database is needed for distribution among a large number of users.

In this chapter, an Independent Component Analysis (ICA)-based technique is proposed for watermark extraction (Yu, Sattar, & Ma, 2002). The proposed ICA-based blind watermarking scheme (Yu & Sattar, 2003) can overcome the problems of the current watermarking scheme for multimedia tracking as mentioned above. No a priori knowledge of watermark locations, strengths, threshold setting, or the original watermark is required for watermark extraction. This watermarking algorithm is found to be very effective in the application of legal data tracking compared to other watermarking algorithms. Therefore, by adopting this ICA-based watermarking approach, an efficient multimedia distribution framework for copyright protection can be accomplished.

A NEW ICA-BASED WATERMARKING SCHEME FOR MULTIMEDIA TRANSACTION TRACKING

This section presents an ICA-based wavelet-domain watermarking scheme. Two watermarks are to be embedded into two selected wavelet subbands of the original image. One is the owner's watermark (or the key of the watermarking system), and the other is a unique watermark assigned to a unique legal user. The ICA technique is applied for extraction of the user's watermark with the help of side information. The proposed scheme is described in the context of watermarking in grayscale images, but this technique can be extended to color images and other digital media such as audio and video.

Proposed Watermark Embedding Scheme

Figure 3 shows a second-level wavelet decomposition of the Lena image into four bands—low-frequency band (LL), high-frequency band (HH), low-high frequency band (LH), and high-low frequency band (HL). Subbands LL and HH are not suitable for watermark embedding among these four subbands. The image quality can be degraded if the watermark is embedding in LL subband since it contains the most important information of an image. Subband HH is insignificant compared to LH and HL subbands, and watermark embedding in such subband find it difficult to survive attacks, such as lossy JPEG compression. Watermark embedding in the two subbands (e.g., LH2 and HL2 of the second-level wavelet decomposition) consisting the middle-frequency pair is to be demonstrated.

Some digital signature/pattern or company logo (**S**), for example, a text image in Figure 4(b), can be used to generate the watermark (**W**) to be embedded. This type of recognizable image pattern is more intuitive and unique than the random sequence to identify the ownership of the work. By using grayscale watermark, our method is found to be more robust against various attacks because the grayscale images can always preserve a certain level of structural information, which are meaningful and recognizable and also can be much more easily verified by human eyes rather than some objective similarity measurements. A masking function—Noise Visibility Function (NVF) (Voloshynovskiy et al., 1999)—is applied to characterize the local image properties, identifying the textured and edge regions where

(g)

the information can be more strongly embedded. Such high-activity regions are generally highly insensitive to distortion. With the visual mask, the watermark strength can be reasonably increased without visually degrading the image quality.

In the next section, the watermark generation and the detailed embedding algorithm are demonstrated, followed by the generation of side information for watermark extraction.

Watermark Embedding Algorithm

Figure 5 illustrates the watermark embedding procedure using second-level decomposed middle-frequency pair (LH2 and HL2):

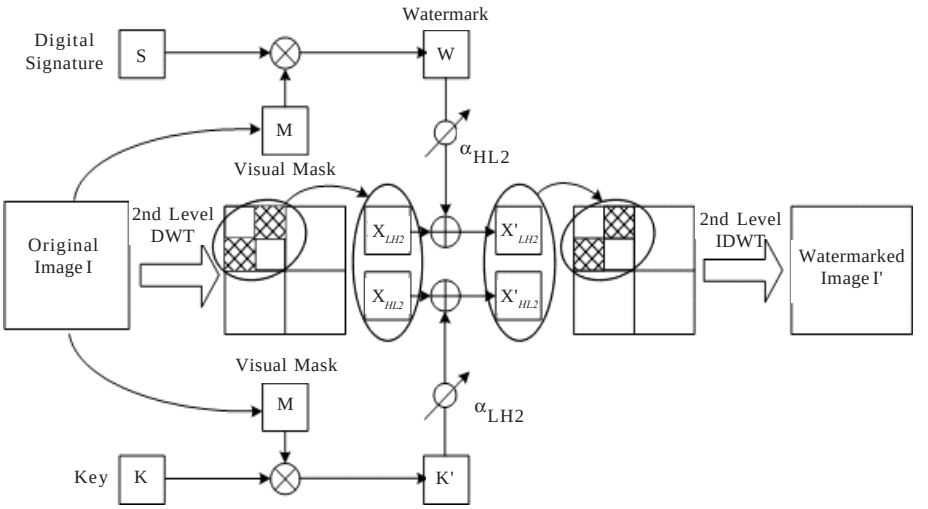
Step 1: Perform the second-level discrete wavelet decomposition of the original image **I**. Subbands LH2 and HL2 are selected for the watermark insertion.

Step 2: The NVF masking function (Voloshynovskiy et al., 1999), **M**, of the original image is generated. Figure 4(a) shows an NVF mask for the Lena image. For the homogeneous region, NVF approaches 1 (white color), and the strength of the embedded watermark approaches 0. The watermark should be embedded in highly textured regions containing edges instead of homogeneous regions. The original signature image, **S**, is modified according to the generated NVF masking function to ensure the imperceptibility of the watermark embedded. The final watermark is quantized into 0–7 gray levels. The expression for watermark generation is given as

$$\boldsymbol{W} = \boldsymbol{Q}_8 [(1 - \boldsymbol{M}) . \boldsymbol{S}], \qquad (1)$$

where $\mathbf{Q}_8$ denotes the quantization operator with 8 gray levels. Figure 4(c) shows a text watermark generated using the NVF masking function shown in Figure 4(a).

Figure 5. The proposed watermark embedding algorithm (for second-level wavelet decomposition)



Step 3: The key **K,** which is also the owner's watermark, is preprocessed by multiplying the same visual mask **M** as

$$\boldsymbol{K'} = \boldsymbol{Q}_8 [(1 - \boldsymbol{M}) . \boldsymbol{K}], \qquad (2)$$

where $\mathbf{Q}_8$ denotes the quantization operator with 8 gray levels. Figure 4(d) gives a key image for ownership authentication. Figure 4(e) shows the modified key after preprocessing by using the NVF masking function in Figure 4(a).

Step 4: The watermark **W** and the modified key **K′**are inserted into the LH2 and HL2 subband, respectively, in the following way:

$$\begin{aligned} \mathbf{X'}_{LH2} &= \mathbf{X}_{LH2} + \alpha_{LH2} \cdot \mathbf{W} = \mathbf{X}_{LH2} + \alpha_{\mathbf{x}} \cdot \mu(|\mathbf{X}_{LH2}|) \cdot \mathbf{W}; \\ \mathbf{X'}_{HL2} &= \mathbf{X}_{HL2} + \alpha_{HL2} \cdot \mathbf{K}2 = \mathbf{X}_{HL2} + \alpha_{\mathbf{x}} \cdot \mu(|\mathbf{X}_{HL2}|) \cdot \mathbf{K'}, \end{aligned} \qquad (3)$$

where **X** and **X′**are the wavelet transform coefficients of the original and the watermarked image, respectively. In Equation 3, α_{LH2} and α_{HL2} denote the weighting coefficients of the watermark embedding in subbands LH2 and HL2, respectively, while μ (| |) denotes the mean of the absolute value. A common control parameter $\alpha_{\mathbf{x}}$ in Equation 3 is used to adjust the watermark embedding strength to preserve a satisfactory quality of the final watermarked image (Peter, 2001).

Step 5: The watermarked image **I′** is obtained by the inverse discrete wavelet transform.

Step 6: Steps 4 and 5 are repeated until the quality of the final watermarked image is satisfactory, for instance, the PSNR (peak signal-to-noise ratio) measure is within the range of 40–50dB. Particularly the parameter $\alpha_{\mathbf{x}}$ is tuned to adjust the watermark strength to obtain the desired embedding result. Decreasing the magnitude of $\alpha_{\mathbf{x}}$ results in a better quality of the final marked image and vice versa. Figure 4(e) shows a watermarked Lena image with PSNR 45.50dB. Table 1 shows the quality of watermarked image (in dB) with respect to the control parameter $\alpha_{\mathbf{x}}$.

Side Information for Watermark Extraction

As discussed earlier, the original data may be unavailable in many real applications for security

Table 1. PSNR (in dB) of the watermarked image with respect to α_x

α_x	0.01	0.05	0.10	0.15	0.20	0.25	0.30

purposes. In order to identify legal users, some side information is necessary to extract the users' watermarks in the absence of the original data. The proposed method allows the owner to create a copy of the data set by embedding only the owner's watermark following the same procedure shown in Figure 5. The owner's watermark is, in fact, the key of the watermarking system that is used for watermark extraction. Using only the owner's copy $\mathbf{I}'_0$ and the key $\mathbf{K}$, the owner is able to identify the recipient of any distributed image by ICA methods. This will be elaborated in the next subsection.

Figure 6 illustrates an owner's copy of the Lena image, embedded with the owner's watermark shown in Figure 4(d). The owner's copy is then obtained by embedding the modified key $\mathbf{K}'$ in the wavelet domain as follows:

$$\mathbf{X}'_{0LH2} = \mathbf{X}_{LH2} + \alpha_{LH2} \cdot \mathbf{K}' = \mathbf{X}_{LH2} + \alpha_{X0} \cdot \mu(|\mathbf{X}_{0LH2}|) \cdot \mathbf{K}';$$
$$\mathbf{X}'_{0HL2} = \mathbf{X}_{HL2} + \alpha_{HL2} \cdot \mathbf{K}' = \mathbf{X}_{HL2} + \alpha_{X0} \cdot \mu(|\mathbf{X}_{0HL2}|) \cdot \mathbf{K}', \quad (4)$$

Figure 6. The owner's copy of the Lena image (256×256 pixels and PSNR = 46.72dB)

where $\mathbf{X}_0$ and $\mathbf{X}'_0$ are respectively the wavelet transform coefficients of the original image and the watermarked channel, and α_{X0} is a control parameter for the visual quality of the watermarked image $\mathbf{I}'_0$.

Suppose an owner wants to authorize a third party, called appointed representative, to do the tracing task. In such case, the owner should also assign a unique watermark to the appointed representative. This representative's watermark would then replace the owner's watermark embedded in the HL2 wavelet subband. It would also be used as the key during watermark extraction. However, at the same time, for ownership verification, the owner's watermark still needs to be embedded in the wavelet subband selected other than the LH2 and HL2 subbands.

Proposed Watermark Extraction Scheme Using the ICA Method

In this section, the concept of ICA is briefly introduced. Then a blind watermark extraction scheme is proposed. The ICA technique is employed for watermark extraction successfully, without knowing the original image and any prior information on the embedded watermark, embedding locations, and strengths.

Independent Component Analysis (ICA)

Independent Component Analysis (ICA) is one of the most widely used methods for performing blind source separation (BSS). It is a very general-purpose statistical technique to recover the independent sources given only sensor observations that are linear mixtures of independent source signals (Hyvärinen, 1999b; Hyvärinen & Oja, 1999; Lee, 1998). ICA has been widely applied in

many areas such as audio processing, biomedical signal processing, and telecommunications. In this paper, ICA is further applied in watermarking for blind watermark extraction.

The ICA model consists of two parts: the mixing process and unmixing process. In the mixing process (Hyvärinen, 1999b; Hyvärinen & Oja, 1999; Lee, 1998), the observed linear mixtures $x_1, \ldots, x_m$ of n number of independent components are defined as

$$x_j = a_{j1}s_1 + a_{j2}s_2 + \ldots + a_{jn}s_n;\ 1 \le j \le m, \quad (5)$$

where $\{s_k, k = 1, \ldots, n\}$ denote the source variables, that is, the independent components, and $\{a_{jk}, j = 1, \ldots, m; k = 1, \ldots, n\}$ are the mixing coefficients. In vector-matrix form, the above mixing model can be expressed as

$$\mathbf{x} = \mathbf{As}, \quad (6)$$

where

$$\mathbf{A} = \begin{pmatrix} a_{11} & a_{12} & \ldots & a_{1n} \\ a_{21} & a_{22} & \ldots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \ldots & a_{mn} \end{pmatrix}$$

is the mixing matrix (Hyvärinen, 1999b; Hyvärinen & Oja, 1999; Lee, 1998), $\mathbf{x} = [x_1\ x_2\ \ldots\ x_m]^T$, $\mathbf{s} = [s_1\ s_2\ \ldots\ s_n]^T$, and T is the transpose operator. For the unmixing process (Hyvärinen, 1999b; Hyvärinen & Oja, 1999; Lee, 1998), after estimating the matrix **A**, one can compute its inverse—the unmixing matrix **B** and the independent components are obtained as

$$\mathbf{s} = \mathbf{Bx}. \quad (7)$$

To ensure the identifiability of the ICA model, the following fundamental restrictions are imposed (Hyvärinen, 1999b; Hyvärinen & Oja, 1999):

- The source signals in the mixing process should be principally statistically independent.
- All independent components s_k, with the possible exception of one component, must be non-Gaussian.
- The number of observed linear mixtures m must be at least as large as the number of independent components n, that is, $m \ge n$.
- The matrix **A** must be of full column rank.

There are many ICA algorithms that have been proposed recently. Some popular ICA methods include Bell and Sejnowski's Infomax (1995), Hyvärinen and Oja's FastICA (1999), Cichocki and Barros' RICA (Robust batch ICA) (1999), Cardoso's JADE (Joint Approximate Diagonalization of Eigen-matrices) (1999), and so on. From the stability standpoint, it is more appropriate to choose RICA or JADE algorithms than Infomax and FastICA algorithms for our watermark extraction process. Both Infomax algorithm and FastICA algorithm require that the values of the mixing coefficients for the sources not be very close (Bell & Sejnowski, 1995; Hyvärinen, 1999a). However, both the watermark and the key are embedded by multiplication with small weighting coefficients to make them invisible. Therefore, the extraction of such weak watermark signals could fail by using Infomax or FastICA algorithm. The extraction results using FastICA algorithm also very much depend on the initial guess of the weighting coefficients (Hyvärinen, 1999a).

Cichocki and Barro's RICA algorithm is an effective blind source separation approach particularly for the temporally correlated sources, since it models the signal as an autoregressive (AR) process (Cichocki & Barros, 1999). The RICA algorithm thus can achieve the best extraction results when both the embedding and extraction are performed in the spatial domain. This is because, generally speaking, the natural images are spatially correlated and can be effectively modeled

as temporally correlated sequences. However, for the proposed watermarking scheme described in this chapter, the watermark is embedded in the wavelet domain instead of the spatial domain. The experimental results show that the JADE algorithm (Cardoso, 1999) outperforms the other ICA algorithms for watermark extraction in our proposed watermarking scheme. This could be due to the use of higher-order statistical parameters in the JADE algorithm, such as fourth-order cumulant, which can model the statistical behavior of the wavelet coefficients more effectively. Therefore, the JADE algorithm is employed to elaborate the watermark extraction process in our proposed watermarking scheme, which will be described next.

Proposed Blind Watermark Extraction Scheme

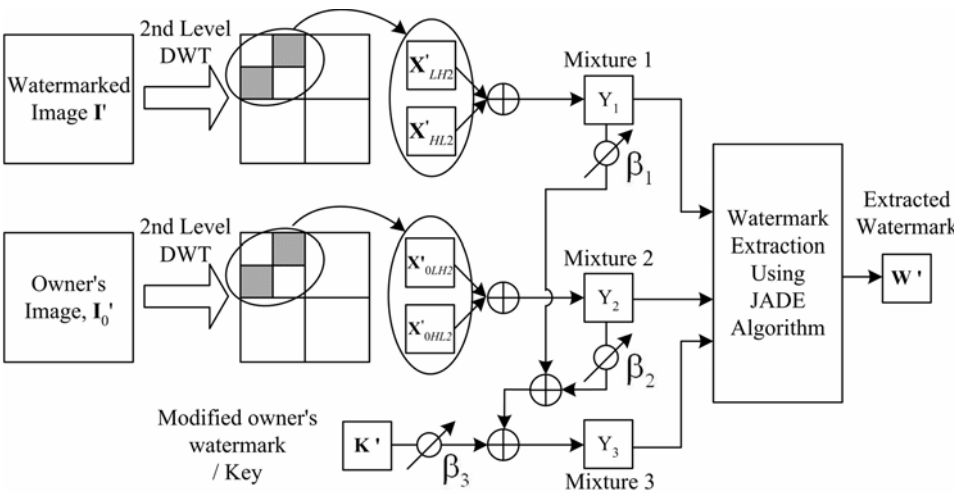
This section proposes the ICA-based blind watermark extraction scheme. Instead of using the original image, only an owner's copy of the original image is required for watermark extraction. The new useful feature of the proposed scheme is that the proposed method does not require previous knowledge of the original watermark, embedding locations, and watermark strengths for extraction. The main idea is to consider two subbands ($\mathbf{X}'_{\mathbf{R}}$) of the watermarked image to have a mixture image of the wavelet transformed image ($\mathbf{X}_{\mathbf{R}}$) of the original image (**I**), the watermark image (**W**), and the modified key (**K**′). Figure 7 shows the proposed blind watermark extraction scheme. Let us denote the received watermarked image as $\tilde{\mathbf{I}}'$. The symbol (~) is to indicate that the received data may or may not be the same as its original watermarked data due to transmission errors or possibly pirate attacks. This symbol (~) is removed in the following for simplicity.

Step 1: Perform the second-level discrete wavelet decomposition of the watermarked image **I**′ in order to obtain the wavelet coefficients $\mathbf{X}'_{LH2}$ and $\mathbf{X}'_{HL2}$ for the two selected subbands of LH2 and HL2.

Step 2: The first mixture signal $\mathbf{Y}_1$ is obtained by

$$\mathbf{Y}_1 = \mathbf{X}'_{\mathrm{LH2}} + \mathbf{X}'_{\mathrm{HL2}}. \tag{8}$$

Figure 7. Proposed blind watermark extraction scheme (using the second-level decomposition)



From Equation 3, $\mathbf{X}'_{\mathbf{R}}$ ($\mathbf{R} \in [LH2, HL2]$) are the mixture observations of the wavelet transform of the original image ($\mathbf{X}_{\mathbf{R}}$), the watermark (**W**), and the modified key (**K**′), therefore, Equation 8 can be rewritten as

$$\mathbf{Y}_1 = \mathbf{X} + \alpha_1 \mathbf{W} + \alpha_2 \mathbf{K}', \quad (9)$$

where $\mathbf{X} = \mathbf{X}_{LH2} + \mathbf{X}_{HL2}$, $\alpha_1 = \alpha_{\mathbf{X}} \cdot \mu(|\mathbf{X}_{LH2}|)$ and $\alpha_2 = \alpha_{\mathbf{X}} \cdot \mu(|\mathbf{X}_{HL2}|)$. It is found that the first mixture signal is a linear mixture of the three independent sources, that is, **X**, **W** and **K**′.

Step 3: Repeat the procedure in Steps 1 and 2 for the owner's image $\mathbf{I}'_0$. The second mixture $\mathbf{Y}_2$ is obtained by

$$\mathbf{Y}_2 = \mathbf{X}'_{0LH2} + \mathbf{X}'_{0HL2}. \quad (10)$$

Similarly $\mathbf{Y}_2$ is also a linear mixture of the wavelet transform of the original image ($\mathbf{X}_{\mathbf{R}}$, $\mathbf{R} \in [LH2, HL2]$) and the key/owner's watermark (**K**). It can be written as

$$\mathbf{Y}_2 = \mathbf{X} + \alpha_3 \mathbf{K}', \quad (11)$$

where $\alpha_3 = \alpha_{\mathbf{X}0} \cdot [\mu(|\mathbf{X}_{0LH2}|) + \mu(|\mathbf{X}_{0HL2}|)]$.

Step 4: From Equations 8 and 10, two mixture images can be obtained containing three sources or independent components in the observations—**X**, the modified key **K**′, and the watermark **W**. As was pointed out earlier, to exploit ICA methods for watermark extraction, it is required that the number of observed linear mixture inputs is at least equal to or larger than the number of independent sources in order to ensure the identifiability of the ICA model (Hyvärinen, 1999b; Hyvärinen & Oja, 1999; Lee, 1998). Therefore, another linear mixture of the three independent sources is needed. The third mixture $\mathbf{Y}_3$ can then be generated by linear superposition of $\mathbf{Y}_1$, $\mathbf{Y}_2$ and **K**′:

$$\mathbf{Y}_3 = \beta_1 \mathbf{Y}_1 + \beta_2 \mathbf{Y}_2 + \beta_3 \mathbf{K}', \quad (12)$$

Figure 8. The extraction result for the user's watermark image (normalized correlation coefficient, r = 0.9790), using JADE ICA method

where β_1 and β_2 are arbitrary real numbers, and b_3 is a nonzero arbitrary real number. Either β_1 or β_2 can be set to zero to efficiently reduce the computational load of ICA. Note that the modified key **K**′ can be easily obtained by regenerating the NVF visual mask and multiplying it to the original owner's watermark **K**.

Step 5: The three mixtures input into the JADE ICA algorithm (Cardoso, 1999) and the watermark image **W**′is extracted. The user of any image copy can be uniquely identified from the signature of the extracted watermark. Figure 8 shows the extracted watermark from the watermarked image shown in Figure 4(g).

PERFORMANCE EVALUATION

The robustness results of the proposed watermarking scheme are shown in this section using the Lena image of size 256×256 when the simulations are performed in the MATLAB 6.5 software environment. A watermarked image (PSNR = 45.50 dB) in Figure 4(g) is generated by setting the watermark strength control parameter $\alpha_{\mathbf{X}}$ as 0.15. In the experiments of watermark extraction, the parameters β_1, β_2, and β_3 are set as 0, 1, 1, respectively, to simplify the computational load of the ICA processing, and Daubechies-1 (Haar) orthogonal filters are employed for wavelet decomposition. In order to investigate the

robustness of the watermark, the watermarked image is manipulated by various signal processing techniques, such as JPEG compression and JPEG2000 compression, quantization, cropping, and geometric distortions. The watermark extraction is performed for the distorted watermarked image and the extracted watermark is compared to the original.

The Performance Index

The performance of the blind watermark extraction result is evaluated in terms of normalized correlation coefficient, *r*, of the extracted watermark $\mathbf{W}'$ and the original watermark $\mathbf{W}$ as

$$r = \frac{\mathbf{W} \cdot \mathbf{W}'}{\sqrt{\mathbf{W}^2 \cdot \mathbf{W}'^2}}. \quad (13)$$

The magnitude range of *r* is [-1, 1], and the unity holds if the matching between the extracted image and the original image is perfect.

Robustness Against Compression and Quantization Attacks

In the following, the robustness of the proposed watermarking scheme is compared with some other blind wavelet-domain watermarking schemes (Peter, 2001) in terms of normalized correlation coefficient *r* as shown in Equation 13. These techniques include Wang, Su, and Kuo's algorithm (1998), Inoue, Miyazaki, Yamamoto, and Katsura's blind algorithm (based on manipulating insignificant coefficients) (1998), Dugad, Ratakonda, and Ahuja's algorithm (1998), Kundur and Hatzinakos' algorithm (1998), and Xie and Arce's algorithm (1998).

Wang et al. (1998) have proposed an adaptive watermarking method to embed watermarks into selected significant subband wavelet coefficients. A blind watermark retrieval technique has been proposed by truncating selected significant coefficients to some specific value. Inoue et al. (1998) have classified insignificant and significant wavelet coefficients using the embedded zerotree wavelet (EZW) algorithm. Thereby, two types of embedding algorithms have been developed in respect to the locations of significant or insignificant coefficients. Information data are detected using the position of the zerotree's root and the threshold value after decomposition of the watermarked image. Dugad et al. (1998) have added the watermark in selected coefficients having significant energy in the transform domain to ensure nonerasability of the watermark. During watermark detection, all the high-pass coefficients above the threshold are chosen and are correlated with the original copy of the watermark. Kundur and Hatzinakos (1998) have presented a novel technique for the digital watermarking of still images based on the concept of multiresolution wavelet fusion, which is robust to a variety of signal distortions. Xie and Arce (1998) have developed a blind watermarking digital signature for the purpose of authentication. The signature algorithm is first implemented in the wavelet-transform domain and is coupled within the SPIHT (Set Partitioning in Hierarchical Trees) compression algorithm.

Figure 9 shows the comparison results in terms of performance index against the JPEG compression. For the proposed scheme, the extracted watermark's correlation decreases gradually with the compression quality factor. The image quality (in PSNR) has degraded significantly to 27 dB when the compression quality becomes quite low to 10%. In such a difficult case, the watermark can still be extracted with the value of *r* equal to 0.2553 for watermark embedding in second-level wavelet decomposition. According to Figure 9, the presented method can perform better than the Wang et al.'s and the Kundur and Hatzinakos' methods, while performing much better than the Inoue et al.'s method in terms of robustness against JPEG compression attack at a very low compression quality factor.

Figure 10 is the extraction comparison against the JPEG2000 compression attacks. The robustness of the proposed scheme is demonstrated up

Figure 9. Comparison of results against JPEG compression attacks

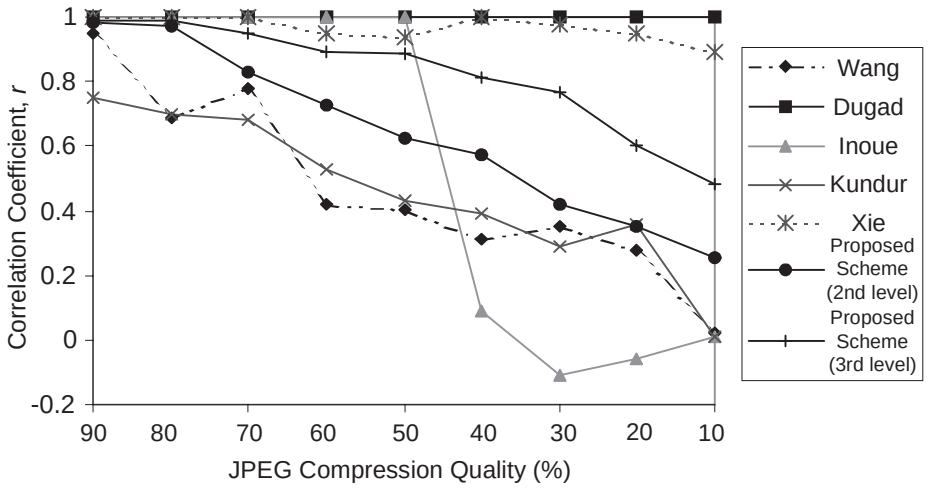


Figure 10. Comparison of results against JPEG2000 compression attacks

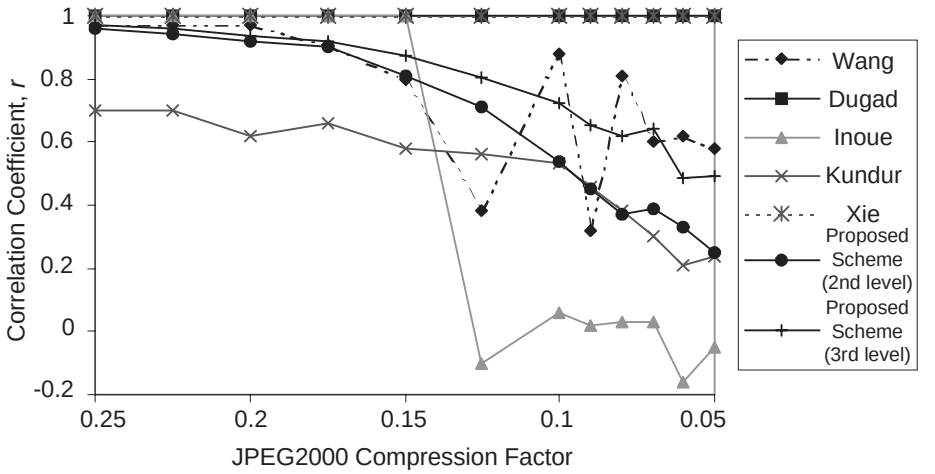
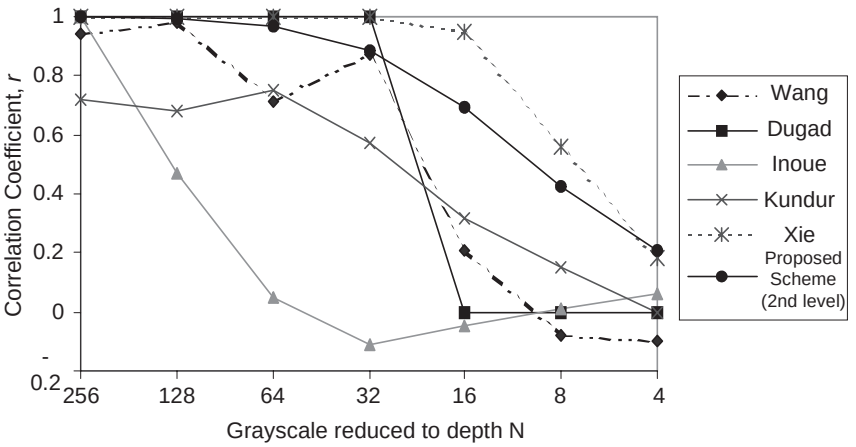


to the compression factor 0.05 or compression rate 0.4 bpp (bit per pixel). The proposed scheme gives better performance than Kundur and Hatzinakos' method, and comparable performance to the Wang et al.'s method. The extraction performance of the Inoue et al.'s method drops sharply when the JPEG2000 compression factor decreases to 0.125. Embedding in the subbands of higher wavelet decomposition level (see curves for third-level decomposition in Figures 9 and 10) can improve significantly the robustness of the proposed scheme against compression attacks.

Figure 11 shows the extraction results against quantization from gray level 256 to gray level 4 per pixel. The proposed scheme has very good robustness result against quantization. The performance of the proposed scheme is comparable to that of the Xie and Arce's method, and much better than the other methods.

From Figures 9 and 10, it is found that Xie and Arce's and Dugad et al.'s methods have excellent robustness performance against JPEG and JPEG2000 compression. In Xie and Arce's algorithm, the watermark is embedded solely in

Figure 11. Comparison of results against quantization



the approximation image (LL subband) of the host image (Xie & Arce, 1998). Although LL subband embedding is robust against compression attacks, the image quality could be degraded visually because the coefficients of this portion always contain the most important information of an image (Peter, 2001). It is claimed that the robustness of Xie and Arce's method very much depends on the number of decomposition levels. Very good robustness result can be obtained by employing a five-level wavelet decomposition using Daubechies-7/9 bi-orthogonal filters (Peter, 2001; Xie & Arce, 1998). On the other hand, in the Dugad et al.'s method, the watermark is embedded in the significant coefficients of all detail subbands (Dugad et al., 1998); therefore, it is more resistant to compression. During the watermark detection using Dugad et al.'s method, the original watermark is required to compute the correlation for the high-pass coefficients with the values above a threshold (Dugad et al., 1998). The presence of the watermark is determined by comparing this correlation with a threshold setting. It is not as general as our proposed scheme where the original watermark and the threshold are not required for watermark extraction.

The experimental results show that the proposed scheme has good robustness against the most prominent attacks such as JPEG and JPEG2000 compression, quantization, and can be comparable to existing blind wavelet-domain watermarking schemes. Experimental results also show that unlike the Xie and Arce's method (Peter, 2001; Xie & Arce, 1998), the choice of the wavelet transform is not critical concerning the robustness issue of the proposed watermarking method (the corresponding results are not included here).

Robustness Against Cropping and Geometric Distortions

Many watermarking techniques cannot survive geometric transformations such as rotation, scaling, and translation (RST) and sometimes cropping attack as well due to the loss of the synchronization of the watermark detector. A solution to such geometric attacks is to apply a resynchronization process (blind or nonblind) before performing the watermark extraction. Nonblind solution requires the presence of the original data, or at least some knowledge of the image features (Dugelay & Petitcolas, 2000). Davoine, Bas, Hébert, and Chassery (1999) have proposed a nonblind solution by splitting the original image into a set of triangular patches. This mesh serves

as a reference mesh and is kept in the memory for synchronization preprocessing. This proposed method, however, is only efficient in the case of involving minor deformations. Johnson, Duric, and Jajodia (1999) have proposed a method to invert affine transformations by estimating the difference in the least square sense between the salient image feature points in the original and transformed images. Kutter (1998) has proposed alternative methods to retrieve the watermark from geometrically distorted image without using the original data. The first method is to preset a part of the watermark to some known values and to use them for spatial resynchronization. This approach decreases the hiding capacity of the useful information, and is also computationally very expensive. The second method proposed by Kutter (1998) is to use self-reference systems that embed the watermark several times at the shifted locations.

Generally speaking, the tuning process can be easier, more accurate and requires less computational load when the original data or reference feature points are available, although it may need extra memory to store the reference data. In our proposed watermarking scheme, original data are not available during the extraction process; however, an owner's or a representative's copy of the data is available. This image copy would be very similar to the original data, thus it is convenient to use it directly as a reference for synchronization of geometric distorted or cropped data. By simple comparisons, the tampered data can be adjusted back to original size and position rapidly and accurately. In the following, the watermark extraction results against attacks of cropping and RST are shown. The effectiveness of employing synchronization preprocessing is demonstrated by showing the significant improvements of extraction results with and without the synchronization.

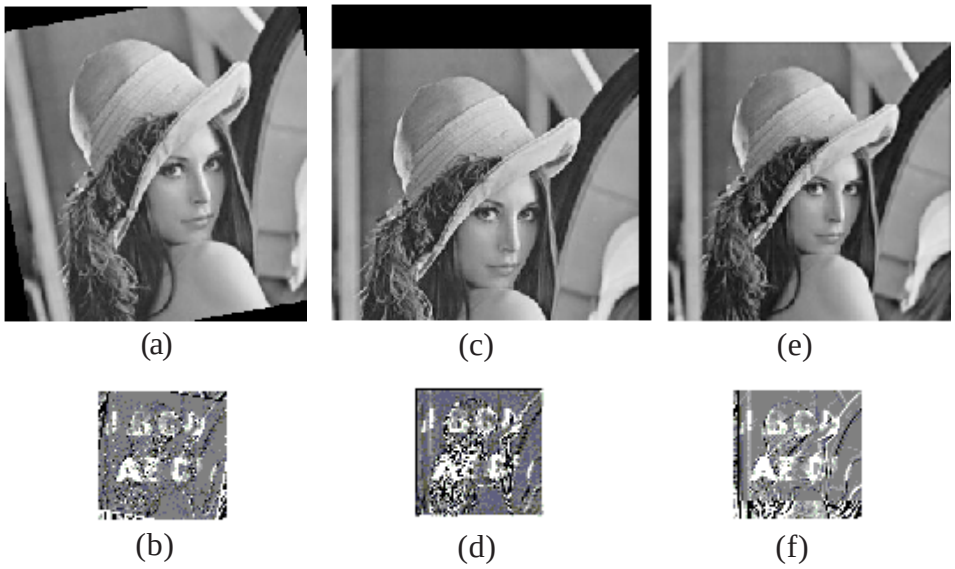
As shown in Figure 12(a), the face portion of a marked Lena image is cropped. By comparison with the owner's Lena image copy, it can be easily detected that the pixels within a square area, with row index from 121 to 180 and column index from 121 to 180, are corrupted. The absence of the watermark information in this corrupted region (by considering both rows and columns from 31 ($\lceil 121/4 \rceil$) to 45 ($\lceil 180/4 \rceil$) results in an undesired overbrightness effect for the extracted watermark due to its high values in the corrupted region. This makes both the subjective and the objective verification measurements quite poor (see Figure 12(b)). One simple solution is to discard the corresponding undesired high-valued pixels from the extracted watermark and replace them with zero-valued pixels. In this way, according to Figure 12(c), the extracted watermark can be recovered mostly with some information loss in the corrupted region. Therefore, the normalized correlation coefficient r is found to increase from 0.2706 to 0.9036, showing the recovery of the low-contrast watermark (compare Figures 12(b) and 12(c)).

Figure 12. (a) A cropped Lena image, (b) the extracted watermark (r = 0.2706), and (c) the extracted watermark after improving the contrast of (b) (r = 0.9036)

(a)

(b) (c)

Figure 13. (a) Lena image rotated by 10º, and (b) the corresponding extracted watermark (r = 0.5847); (c) Lena image downsized by reducing the number of rows and columns by 1/4, and (d) the corresponding extracted watermark (r = 0.4970); (e) Lena image translated to the left and downward by 10 and 36 lines, respectively, and (f) the corresponding extracted watermark (r = 0.5356)



The watermark extraction of the geometrically distorted image may fail due to the loss of synchronization. A resynchronization preprocessing of the received data is necessary to tune it back to the right positions or sizes before input in the watermark decoder. However, the side information in the proposed watermarking scheme—the owner's or the representative's copy of the original image—provides a good reference to assist the synchronization process, and the watermark extraction performance is consequently improved. Figures 13(b), 13(d), and 13(f) show the extraction results under attacks of rotation, scaling, and translation (RST), respectively, after the synchronization process. The watermark extraction results are satisfactory in terms of both the subjective visualization and the objective similarity measurement.

Discussions

Watermarking versus Fingerprinting

To enforce IP rights for multimedia distribution over the Internet, it requires not only verification of the legal recipient, but also proof of the rightful ownership of the original work. The term *fingerprinting* (Katzenbeisser & Petitcolas, 2000; Arnold et al., 2003; Trappe, Wu, Wang, & Liu, 2003) is closely related to watermarking in the context of traitor tracking problem. Fingerprinting technique involves the embedding of different watermarks into each distributed copy of the work. The purpose of fingerprinting is to identify the legal recipient rather than the source of digital data. Thus, using the fingerprinting technique alone is not sufficient to enforce IP rights protection in multimedia distribution systems, as the owner

cannot provide trustful evidence for proving the ownership. This chapter presents a multiple digital watermarking framework that can achieve the above two demands, that is, identifying the owner and the recipient of the distributed content.

Moreover, fingerprinting has another distinct interpretation, which does not involve the concept of digital watermarking at all. It refers to the extraction of unique features, such as semantically relevant or characteristic features from multimedia signals, in order to distinguish itself from other similar objects (Katzenbeisser & Petitcolas, 2000; Arnold et al., 2003). The extracted features are normally stored separately as signatures for authentication of the content rather than inserting them into the content as watermarks. This concept falls out of scope of this chapter.

Summary and Future Work of the Proposed Watermarking Scheme

The proposed ICA-based watermarking scheme shows its main advantage in terms of generality. Unlike other methods, no a priori information about the original watermark, embedding locations, strengths, as well as the threshold is needed for our blind watermark extraction scheme. Therefore, it is possible to extract the watermark from any copy of the watermarked image, where the embedded watermark is previously unknown. The other advantage of the proposed ICA-based method is that without using a pre-defined threshold, the extracted watermark could simply be verified from visual inspection instead of using the correlation-based matching technique with a threshold setting. This is possible because the embedded watermark used in our scheme is a readable digital signature image or a logo image. The generality of the proposed scheme implicates this method to be a quite useful tool for the transaction tracking in the application of Internet distribution. The only disadvantage to achieving the generality using ICA-based technique could be the complexity of the ICA itself. In this chapter, this has been compromised by the use of JADE algorithm, which is simple and computationally efficient. Furthermore, there are only three mixing sources (i.e., the original data, the key, and the watermark) involved in the presented watermarking scheme, which enables our ICA-based extraction processing to be fast.

In the future, more experiments need to be carried out in order to evaluate the resilience of this scheme against other types of attacks. For example, the collusion attacks and the possible counterattacks for multimedia distribution systems are to be investigated to improve the present scheme. The issue on the generation of a better perceptual mask as used to simulate the human visual system should also be studied to improve the visual quality of the watermarked data.

CONCLUDING REMARKS AND FUTURE TRENDS

This chapter investigates the multimedia transaction tracking issue by means of digital watermarking. One feasible solution of using an ICA-based watermarking technique is presented to perform ownership verification and traitor tracking for multimedia distribution through public networks. Two watermarks consisting of an owner's watermark for ownership identification and a user's watermark for unique recipient identification are embedded. Watermark is obtained by modification of the signature image with a visual mask in order to prevent the perceptual quality degradation of the watermarked image. The watermarks are inserted in the two middle frequency subband pair at the higher wavelet decomposition level (say second/third decomposition level) of the original image. Without requiring any information such as original watermark, embedding locations, and strengths, our proposed scheme can extract the user's watermark with the help of an owner's copy of the image and the owner's watermark/key. Experimental results show that the proposed wa-

termarking scheme can provide good resistance to attacks of image compression, quantization, cropping, and geometric transformations.

It has been elaborated in this chapter that the ICA-based watermarking scheme can be employed as an efficient tool to trace the recipient of the distributed content. From the general perspective, the challenging issues of digital watermarking in the applications of transaction tracking for the Internet distribution include the following criteria:

- The original data are not available during extraction of the recipient's watermark. Thus the watermarking technique should be blind.
- No prior information about the embedded watermark and the corresponding locations is available for watermark extraction.
- In order to present as trustful evidence in the court to litigate the pirate, a highly robust watermarking scheme against common signal possessing attacks as well as collusion attacks is needed.
- For some applications, for example, searching for the pirated watermarked image using Web crawlers, it is required that the watermarking scheme is able to extract the watermark easily and with low complexity.

There is no doubt that transaction tracking is a more difficult task than copyright protection by means of digital watermarking. More general watermarking techniques are desired such that no original data and prior watermark information is needed for extraction, while providing the methods to be reliable, robust, and computationally efficient.

Another requirement to enforce the IP rights of the distributed work could be such that the owner should be able to detect any illegal attempts manipulating the content. Fragile watermark should be inserted as well in order to protect the integrity of the content. The authentication watermark should be then very sensitive to various attacks and, therefore, able to locate possible modifications. In such scenario, three watermarks would be hidden in the work in order to verify the owner, to identify the user, and to authenticate the content. Since the information-hiding capacity of the cover media is limited, we have further challenges to investigate, for example, how to compromise the three demands including the information-hiding capacity and the imperceptibility and robustness of the hidden watermark.

There has been no rush yet to embrace any of the current watermarking schemes for IP rights protection in multimedia distribution application. In fact, time is still needed for thorough inspection and appraisal to find solutions for better digital watermarking schemes. Before that, scientists and researchers have to fully understand the practical requirements associated with the real problems. In the meantime, the main challenge for researchers is to develop even more transparent and decodable schemes for robust or fragile watermarking, or perhaps to meet more demands required for a practical multimedia distribution system.

ACKNOWLEDGMENT

The authors would like to thank Professor N.G. Kingsbury for his valuable suggestions and comments that helped to improve the proposed watermarking scheme for transaction tracking in multimedia distribution applications. They are also thankful to Professor K.-K. Ma for contributing useful discussion regarding the use of ICA in image watermarking.

Chapter 3.13
Digital Watermarking Schemes for Multimedia Authentication

Chang-Tsun Li
University of Warwick, UK

ABSTRACT

As the interconnected networks for instant transaction prevail and the power of digital multimedia processing tools for perfect duplication and manipulation increases, forgery and impersonation become major concerns of the information era. This chapter is intended to disseminate the concept of digital watermarking for multimedia authentication. Issues and challenges, such as security, resolution of tamper localization, and embedding distortion, of this technical area are explained first. Three main categories of watermarking approaches, namely fragile, semi-fragile, and reversible schemes, to the issues and challenges are then presented. Merits and limitations of specific schemes of each category are also reviewed and compared.

INTRODUCTION

As the interconnected networks for instant transaction prevail and the power of digital multimedia processing tools for perfect duplication and manipulation increases, forgery and impersonation become major concerns of the information era. As a result, the importance of authentication and content verification became more apparent and acute. In response to these challenges, approaches conveying the authentication data in digital media have been proposed in the last decade. Applications for multimedia authentication can be found in many areas. For example:

- **Medical image archiving**: The authentication data of patients can be embedded at the time when their medical images are taken by the hospital to protect the patients' rights when medical malpractice happens and has to be resolved in court.
- **Imaging/sound recording of criminal events**: Authentic imaging or recording of legally essential event or conversation could lead to breakthrough in criminal cases while maliciously tampered imaging/recording, if not detected, could result in wrong ruling.
- **Accident scene capturing for insurance and forensic purposes**: Similar applications of the technique as mentioned above could be

useful in protecting the rights of the parties including the insurance company involved in accidents or natural disasters.

- **Broadcasting**: During international crises, tampered or forged media could be used for propaganda and manipulating public opinion. Therefore, broadcasting is an area where multimedia authentication is applicable.
- **Military intelligence**: Multimedia authentication allows the military to authenticate whether the media they received do come from a legitimate source and to verify whether the content is original. Should the content be manipulated, an effective authentication scheme is expected to tell as much information about the manipulation as possible (e.g., location of tampering).

The aforementioned list is not intended to be exhaustive but just to identify some possible applications of multimedia authentication.

As Lou, Liu, and Li (2004) described, depending on the ways of conveying the authentication data for digital media, authentication techniques can be roughly divided into two categories: labeling-based techniques (Chen & Leiss, 1996; Friedman, 1993; Lin & Chang, 2001; Lou & Liu, 2000; Queluz, 2001; Schneider & Chang, 1996) and watermarking-based techniques (Hsieh, Li, & Wang, 2003; Li, Lou, & Chen, 2000; Li & Yang, 2003; Xie & Arce, 2001). The main difference between these two categories of techniques is that in labeling-based authentication, the authentication data or the signature of the medium is written into a separate file or a header that is separated from the raw data stored in the same file, while in watermarking-based authentication, the authentication data is embedded as watermark in the raw data itself.

Compared to watermarking-based techniques, labeling-based techniques potentially have the following advantages:

- The data-hiding capacity of labeling-based techniques is higher than that of watermarking.
- They can detect the change of every single bit of the image data if *strict* integrity has to be assured.

Given the above benefits, why would researchers propose watermarking approaches? The following are some of the issues regarding the use of labeling-based techniques:

- In labeling-based techniques, storing digital signatures in a separate file or in separate header segments of the file containing the raw data incurs significant maintenance overhead and may require extra transmission of the signature file.
- When the signed medium is manipulated, the embedded signature is not subjected to the same process of manipulation, which makes it difficult to infer what manipulation has been done and to pinpoint the temporal and spatial localities where tampering occurs.
- Traditional digital signatures used for labeling are not suitable for lossy or progressive transmission applications. For example, in light of network congestion in a progressive transmission scenario, low-priority layers of the medium (usually the high-frequency components or the details) are likely to be dropped, making the received data differ from the original. In this case, the received signature generated based on the original medium by the sender will not match its counterpart generated according to the received medium by the recipient. As a result, the received medium will fail authentication.
- Transcoding or converting the format of media-protected with labeling-based techniques is not always possible. For example, converting a JPEG image with its authentica-

tion data/signature stored in the header to an image format without any header segments means that the signature has to be discarded, making authentication impossible at a later stage.

On the contrary, watermarking-based approaches embed the authentication data into the raw data of the host media directly, which will be subjected to the same possible transformation the host media would undergo. Therefore, fragile and semi-fragile digital watermarking schemes do not have the first two aforementioned problems. Moreover, by sensibly designing the embedding algorithm, semi-fragile watermarking schemes can also circumvent the last two problems mentioned above. Nevertheless, readers are reminded that no superiority of the semi-fragile schemes over the fragile schemes is implied here. In deciding whether to make the scheme fragile or semi-fragile, the designer has to take the nature of applications and scenario into account since no single optimal scheme is available for all applications. Because of their merits, the rest of this chapter will focus on the design of watermarking-based schemes.

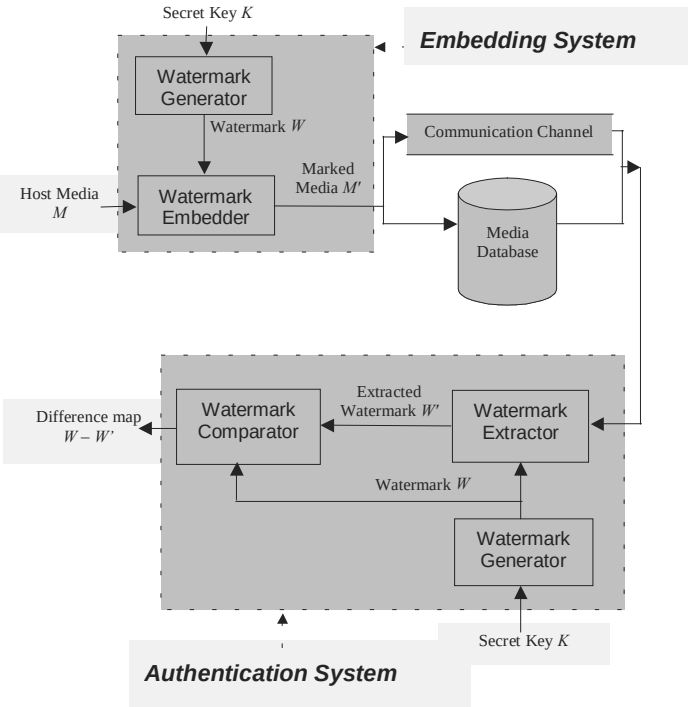
BACKGROUND

Various types of watermarking schemes have been proposed for different applications. For the purpose of copyright protection, embedded watermarks are expected to survive various kinds of manipulation to some extent, provided that the altered media is still valuable in terms of commercial significance or acceptable in terms of fidelity. Therefore, watermarking schemes for copyright protection are typically robust (Kutter, Voloshynovskiy, & Herrigel, 2000; Lu, Huang, Sze, & Liao, 2000; Trappe, Wu, & Liu, 2002; Wu & Liu, 2003), that is, they are trying to ignore or remain insensitive to the influence of malicious or unintentional attacks. On the other hand, in medical, forensic, broadcasting, and military applications where content verification and identity authentication are much more of a concern, more emphases are on the capability of the watermarking schemes to detect forgeries and impersonation. For example, the staff at a military headquarter always has to be sure that the digital images received come from the right people and that the contents are original. Therefore, this type of watermarks is usually fragile or semi-fragile and is expected to be sensitive to attacks (Li & Yang, 2003; van Leest, van der Veen & Bruekers, 2003; Winne, Knowles, Bull & Canagarajah, 2002; Wong & Memon, 2000; Xie & Arce, 2001). In addition to these two categories of schemes, some hybrid schemes incorporating a robust watermark and a fragile/semi-fragile watermark in attempt to provide copyright protection and authentication simultaneously have also been proposed (Deguillaume, Voloshynovskiy, & Pun, 2003).

This chapter deals with watermarking schemes for authentication purpose. A general authentication framework based on digital watermarking is illustrated in Figure 1. Usually, a secret key K available on both the embedding and authentication sides is used to generate a watermark to be embedded into the host media. The marked media is then delivered via the communication channel (e.g., Internet, satellite, etc.) or stored in a database. To authenticate the marked media, the same secret key is used to generate the original watermark so as to be used for extracting and comparing against the embedded version. The difference map, the output of the authentication system, tells the authenticity of the media.

Fragile/semi-fragile digital watermarking is about embedding a small amount of information, the watermark, into the host media so that the watermark can be extracted later from the marked media to authenticate the identity of the embedder and to verify the content integrity of the media. The watermark can be an ID number of the embedder, a visually meaningful logo, or a sequence of random numbers generated with a

Figure 1. A general authentication framework based on digital watermarking



secret key representing the embedder. The media can be text, audio, speech, image, video, multimedia, or a combination of them all.

When designing a watermarking scheme for digital media authentication, two categories of attacks have to be taken into consideration: content-targeting attacks and scheme-targeting attacks. Content-targeting attacks aim at manipulating the content of the media without taking into account the protection measures provided by the authentication algorithm. Common content-targeting attacks threatening digital media can be classified into two types:

- **Local tampering**: Typical examples of this type of tampering include removal of original objects/features and/or addition of new objects/features.
- **Global manipulations**: Typical examples of this type of manipulations include scaling, clipping, cropping, low-pass filtering, and histogram equalization.

Scheme-targeting attacks aim at defeating the security of the authentication scheme so that the scheme fails to detect malicious content manipulations. This type of attacks always goes along with content-targeting attacks because the ultimate goal of any malicious attacks is to tamper the content of the media. Typical examples of scheme-targeting attacks are as follows:

- Cover-up/cut-and-paste (Barreto, Kim, & Rijmen, 2002), which is an action of cutting one region/block of the image and pasting it somewhere else in the same or different image.
- Vector quantization attack (Wong & Memon, 2000) (also known as birthday attack [Barreto et al., 2002], the Holliman-Memon counterfeiting attack [Holliman & Memon, 2000], or collage attack [Fridrich, Goljan, & Memon, 2000]), which is devised on the basis of the so-called birthday paradox (Stallings, 1998, Appendix 8.A): *What is*

the minimum population size such that the probability that at least two of the people have the same birthday is greater than 0.5? According to birthday paradox, using a hash function that produces a bit string of length l, the probability of finding at least two image blocks that hash to the same output is greater than 0.5 whenever roughly $2^{l/2}$ watermarked image blocks are available. The idea of the attack is to forge a new watermarked image (a collage) from a number of authenticated images watermarked with the same key and the same logo/watermark by combining portions of different authenticated images while preserving their relative positions in the image. Fridrich, Goljan and Memon (2000) showed that counterfeiting is possible even when the logo is unknown to the attacker provided that a larger number of images watermarked with the same key are available.

- Transplantation attacks derived by Barreto, Kim, and Rijmen (2002) work as follows. Let $I'_A \rightarrow I'_B$ denote that the hashing of image block I'_B involves the information about I'_A. Now, if images I' and I'' have blocks with following dependence relationships:

$$\ldots \rightarrow I'_A \rightarrow I'_X \rightarrow I'_B \rightarrow I'_C \rightarrow \ldots$$
$$\ldots \rightarrow I''_A \rightarrow I''_X \rightarrow I''_B \rightarrow I''_C \rightarrow \ldots$$

and block I'_A is identical to I''_A, I'_B is identical to I''_B, and I'_C is identical to I''_C, but I'_X is not identical to I''_X. Then the block pairs (I'_X, I'_B) and (I''_X, I''_B) are interchangeable without being detected by schemes adopting deterministic dependence (Li et al., 2000; Wong & Memon, 2000; Yeung & Minzter, 1997), that is, the information involved or dependent upon is deterministic. Barreto et al. (2002) further indicated that merely increasing the number of dependencies could not thwart the transplantation attack. For example, let $I_A \leftrightarrow I_B$ denote that the hashing of each block involves the information about the other. Now, if the following dependence relationships exist

$$\cdots \leftrightarrow I'_A \leftrightarrow I'_B \leftrightarrow I'_X \leftrightarrow I'_C \leftrightarrow I'_D \leftrightarrow \cdots$$
$$\cdots \leftrightarrow I''_A \leftrightarrow I''_B \leftrightarrow I''_X \leftrightarrow I''_C \leftrightarrow I''_D \leftrightarrow \cdots,$$

the triplet (I'_B ,I'_X , I'_C) and (I''_B ,I''_X , I''_C) are interchangeable if block I'_D is also identical to I''_D.

Based on the above discussions, it is clear that content-targeting attacks are naïve and can only succeed when the attacked media is *not* watermarked. Scheme-targeting attacks are more sophisticated and intended for making content-targeting attacks undetectable.

To be considered effective, a fragile/semi-fragile watermarking scheme must have the essential capabilities of detecting content-targeting attacks. Moreover, an effective fragile/semi-fragile watermarking scheme should show no security gaps to various kinds of scheme-targeting attacks such as cover-up, transplantation, and vector quantization attacks. Block-wise dependence is recognized as a key requirement to thwart vector quantization (Fridrich et al., 2000; Holliman & Memon, 2000; Li et al., 2000; Li & Yang, 2003; Wong & Memon, 2000). However, it is also proved that the dependency with deterministic context is susceptible to transplantation attack or even simple cover-up attack (Barreto et al., 2002). Nevertheless, Li and Yang (2003) pointed out that even nondeterministic block-wise dependency (i.e., the neighboring relationship among individual pixels in the block is nondeterministic) as adopted in Fridrich, Goljan, and Baldoza (2000) is still vulnerable to cropping attack.

Although spatial-domain approaches are effective for the applications where lossy compression is not acceptable (e.g., medical imaging), lossy compression standards such as JPEG and MPEG are commonly adopted for Internet transmission and multimedia storage in order to make efficient

use of bandwidth and disk space. These two requirements make transform-domain approaches desirable. It is common in transform-domain schemes to watermark only a few selected transform coefficients in order to minimize embedding distortion. However, Hsieh, Li, and Wang (2003) pointed out that leaving most of the coefficients unmarked results in a wide-open security gap for attacks to be mounted on them. A solution Hsieh et al. (2003) proposed is to implicitly watermark all the coefficients by registering/blending the zero-valued coefficients in the watermark and involving the unembeddable coefficients during the process of embedding the embeddable ones.

However, fragile watermarking is intolerant not only to malicious attacks but also to content-preserving or incidental operations (e.g., further compression, transcoding, bit rate scaling, and frame rate conversion), which do not change the semantics or content of the media. Those content-preserving operations are sometimes necessary in many multimedia applications wherein fragile watermarking is not practical. Semi-fragile watermarking (Kundur & Hatzinakos, 1999; Xie & Arce, 2001) is the technique that allows those content-preserving operations while intolerant to malicious content-altering operations such as removal of original objects from the media.

In some applications, such as medical imaging and forensic image archiving, even imperceptible distortion due to watermark embedding is not acceptable. For example, in legal cases of medical malpractice, any distortion of an image, even if it is a result of watermark embedding itself, would cause serious debate in court. Therefore, the capability of recovering the original unwatermarked media from the authenticated watermarked version is of significant value for this type of application. A watermarking scheme with this capability is referred to as reversible (van Leest, van der Veen, & Bruekers, 2003), erasable (Cox, Miller, & Jeffrey, 2002). or invertible watermarking (Fridrich, Goljan, & Du, 2001).

In addition, it is more practical for a watermarking scheme to be able to verify the authenticity and integrity of the media without referring to the original versions. This characteristic is commonly called obliviousness or blind verification. In a more restrictive sense, obliviousness can also mean that no a priori knowledge (e.g., image index) about the image is required in the authentication process.

Low false-positive and false-negative rates are also important factors for effective schemes. False-positive rate is the occurrence rate that the watermark detector extracts a watermark that was *not* actually embedded. On the contrary, false-negative rate is the occurrence rate that the watermark detector fails to extract an embedded watermark. Low false-positive and false-negative rates are usually in conflict with low embedding distortion because reducing false-positive and false-negative rates usually means increasing the amount of watermark, which inevitably will inflict higher distortion on the quality of the watermarked media.

The aforementioned challenges and attacks do not constitute an exhaustive list since more new attacks are expected to be devised in the future. Nevertheless, at present, an effective watermarking scheme for authentication purpose should have the capability of thwarting known attacks.

WATERMARKING APPROACHES TO AUTHENTICATION

This section is intended to introduce some solutions to the problems posed previously. Several watermarking approaches will be discussed.

Fragile Watermarking Schemes

Among the proposed spatial-domain fragile watermarking techniques, the Yeung-Mintzer scheme (Yeung & Minzter, 1997) is one of the earliest and frequently cited. In Yeung and Minzter (1997),

the watermark is a visually significant binary logo, which is much smaller than the image to be marked and is used to form a binary image as big as the image. Watermark embedding is conducted by scanning each pixel and performing the watermark extraction function based on a lookup table generated with a secret key. If the extracted watermark bit is equal to the authentic watermark bit, the pixel is left unchanged; otherwise, the gray scale of the pixel is adjusted until the extracted watermark bit is equal to the authentic one. Because of its pixel-wise scanning fashion, local tampering can be localized to pixel accuracy. The pixel-wise watermarking fashion is actually a special case of the block-wise style with block size equal to 1.

However, due to the lack of interrelationship among neighboring pixels during the watermarking process, their scheme is vulnerable to cover-up attacks when there are local features surrounded by a relatively larger smooth background. For example, without knowing the secret key, a handgun on the floor of a criminal scene can still be covered up by pasting a patch taken from the background. The scheme is also vulnerable to vector quantization attack (Fridrich et al., 2000; Holliman & Memon, 2000; Wong & Memon, 2000). Another attack derived by Fridrich et al. (2000) that can be mounted against the Yeung-Mintzer scheme is that the lookup table and the binary logo can be inferred when the same lookup table and logo are reused for multiple images.

Another well-known fragile watermarking technique is Wong's public-key scheme reported in Wong (1998). In this scheme, the gray scales of the least significant bits (LSBs) of the original image are first set to zero. Then the LSB-zeroed image is divided into blocks of the same size as that of a watermark block. The image size together with each LSB-zeroed image block is then provided as inputs to a hash function and the output together with the watermark block are subjected to an exclusive-or (XOR) operation. The result of the XOR operation is then encrypted using a private key of the RSA public-key cryptosystem and embedded in the LSBs of the original image. To verify the integrity of the received image, it is again divided into blocks and the encrypted data embedded in the LSBs of each block is then extracted and decrypted with a public key. Meanwhile, the LSB-zeroed version of each received image block together with the image size of the transmitted image are again taken as inputs to the same hash function as that used by the image sender. The output of the hash function and decrypted data are subjected to the XOR operation in order to reveal the watermark. The revealed watermark is then compared with the perfect watermark in the preestablished database at the receiver side. This scheme marries cryptography and watermarking elegantly and indeed works well in detecting cropping and scaling.

However, like the Yeung-Mintzer scheme, this method is also block-wise independent, and, therefore, vulnerable to cover-up and vector quantization attacks. Since the block size of Wong's scheme is 64, according to birthday paradox, given 2^{32} blocks, vector quantization attack can be successful with relatively high probability. This is possible in the applications of medical image archiving where large image database is maintained. Due to the lack of mutual dependence among neighboring blocks during the watermarking process, this scheme is also vulnerable to transplantation attacks. Moreover, the output length of the hash function sets the lower bound on the block size. Thus, the tampering localization accuracy is limited.

To thwart vector quantization attack, Wong and Memon (2000) proposed an improved scheme by adding an image index and a block index to the inputs of the hash function. With this new version, to forge each block, the choices for the attacker are now limited to only the blocks from all authenticated images with the same block index. Adding the image index is one step further to secure the scheme against vector quantization attack. In this case, the image index is just like

a unique serial number of the image; therefore, vector quantization cannot succeed. However, this idea works at the expense of requiring the verifier to have the a priori knowledge about the image index, which limits its applicability to some extent. For example, an intelligence agent in a hostile territory has to send the index of the image he/she wants to transmit through a secure channel to the verifier.

Recognizing the importance of establishing dependence among neighboring pixels or blocks, Li, Lou, and Chen (2000) proposed a scheme that uses a binary feature map extracted from the underlying image as watermark. The watermark is then divided into blocks of size 32×16 pixels. Block-wise dependence is established by blending the neighboring blocks before encrypting and embedding into LSBs of the image. This method is effectively resistant to vector quantization and cover-up attacks and requires no a priori knowledge of the original image. However, the accuracy of localization is limited by the block size. Moreover, like Wong's (1998) scheme, this scheme is also vulnerable to transplantation attacks because the contextual dependence is established based on deterministic information. To circumvent these drawbacks, Li and Yang (2003) further proposed a scheme that is immune to transplantation attacks and is significantly accurate in locating tampering. To watermark the underlying image, the scheme adjusts the gray scale of each pixel by an imperceptible quantity according to the consistency between a key-dependent binary watermark bit and the parity of a bit stream converted from the gray scales of a secret neighborhood. The members of the secret neighborhood are selected according to the watermark sequence generated with the secret key, and therefore cannot be deterministically reestablished by the attacker. However, it is a spatial-domain approach, which is not suitable for transform-domain applications.

Although there are some transform-domain schemes reported in the literature, a common security gap inherent in many of them (Winne, Knowles, Bull, & Canagarajah, 2002; Wu & Liu, 1998; Xie & Arce, 2001) is that they neither explicitly nor implicitly watermark all the transform coefficients. As a result, manipulation of those unwatermarked coefficients will go unnoticed. For example, in the wavelet transform-domain approach proposed by Winne, Knowles, Bull, and Canagarajah (2002), to minimize embedding distortion and maintain high localization accuracy, only the coefficients of the high frequency subbands at the finest scale of the luminance component are watermarked. All the other coefficients and components are neither watermarked nor involved during the watermarking process of the embeddable coefficients. In Xie and Arce (2001), to make the scheme semi-fragile, only the LL component of the coarsest scale (i.e., the approximate of the original image) is involved in generating the signature, which is then used as the watermark. To minimize embedding distortion, only the coefficients of the finest scale are watermarked. Consequently, tampering the coefficients in other subbands and scales will certainly go undetected. For example, locally tampering the three unwatermarked high-frequency subbands at the coarsest scale that are not involved in generating the signature is highly likely to change or at least destroy the semantic meaning of the watermarked image without raising alarm.

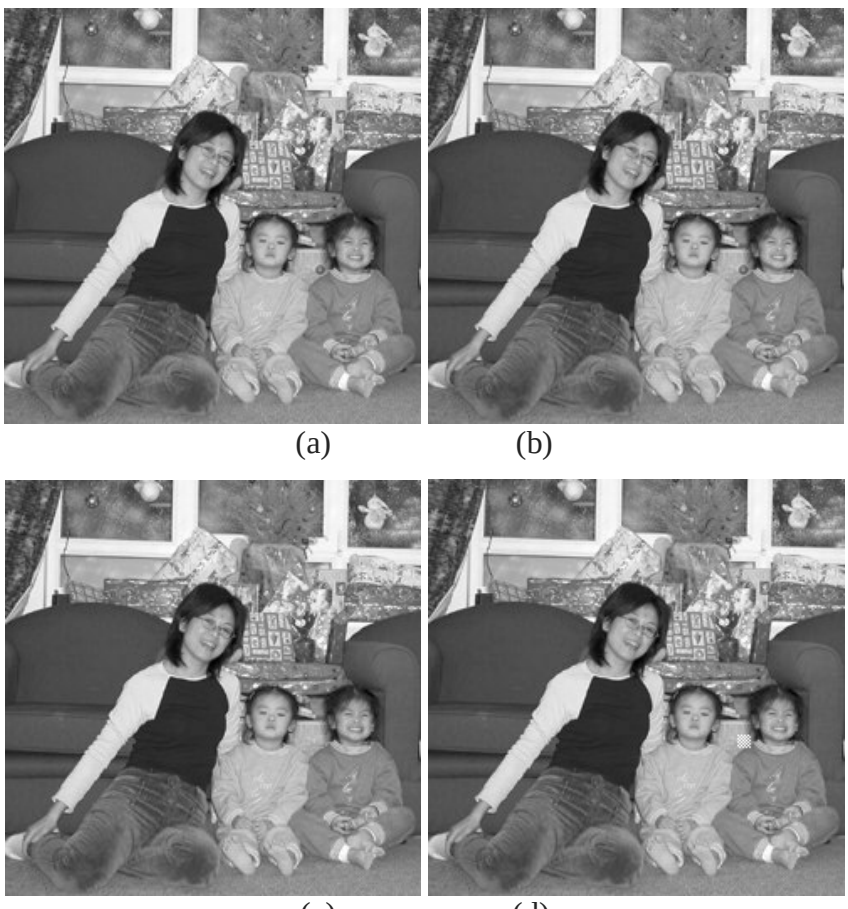
Given the limitations of the reviewed schemes, Hsieh, Li, and Wang (2003) designed a transform-domain scheme, which is immune to the aforementioned attacks and provides protection for *all* the transform coefficients without explicitly watermarking all of them. To embed the watermark, the target image X is first DCT transformed and quantized. A binary image A as big as X is generated with a secret key. A second binary image, B, is then created so that all of its pixels corresponding to the nonzero-valued coefficients are set to 1 and the others set to 0. B is intended to serve the purpose of registering the positions of the zero-valued coefficients. A binary watermark W is then created by taking the

result of XOR operation on the binary images *A* and *B*. Like *X*, *W* is also divided into blocks of 8×8 pixels. For each DCT block X_i, four nonzero coefficients $X_i(h)$, $X_i(h\text{-}1)$, $X_i(h\text{-}2)$, and $X_i(h\text{-}3)$ with their frequencies lower than or equal to a middle frequency *h* are identified as watermarkable. The four selected coefficients $X_i(j)$, $j \in [h\text{-}3, h]$, are modulated based on their corresponding watermark bits $W_i(j)$ and a secret sum $S_i(j)$ such that Equation (1) is satisfied.

$$\text{Parity}\,(S_i(j) \copyright X_i(j)) = W_i(j) \qquad (1)$$

where *Parity*(×) is a function which returns 1 or 0 as output to indicate that the number of '1' bits of its argument is *odd* or *even*. © is an operator that concatenates $S_i(j)$ and $X_i(j)$ expressed in two's complement format. The secret sum $S_i(j)$ is the sum of the nonzero unwatermarkable coefficients selected according to their corresponding watermark bits and $W_i(j)$ from a neighborhood $N_i(j)$ consisting of the DCT block X_i and its eight closest neighboring blocks. It canbe expressed as

Figure 2. (a) Original image. (b) Watermarked image. (c) Attacked image. The doorknob between the twins' heads in the watermarked image has been masked. (d) Authentication result. The shaded block between the twins' heads indicates that the received image has been locally tampered with.



(a) (b)

(c) (d)

$$S_i(j) = \sum_{m \in N_i(j)} \sum_{n \in [h-3,h]} (W_m(n) \oplus W_i(j)) \cdot X_m(n) \quad (2)$$

The watermarking process repeats until all the blocks are marked. To authenticate and verify the received image, the verifier performs the same operations as applied on the embedding side in the reversed order to extract the embedded watermark and compares it with the original watermark generated in the same manner as that adopted by the embedder. A set of experimental results of this scheme is shown in Figure 2. Figure 2(a) is the original image while Figure 2(b) is the watermarked image. These two images show that the embedding distortion is invisible to human visual system (HVS). Figure 2(c) shows that the doorknob between the twins' heads has been removed (compare the difference between Figure 2(b) and 2(c)). This is a typical example of localized attack. Detected by the authentication scheme, the shaded block between the twins' head indicates that the image has been locally tampered with. These two figures show that the scheme is capable of localizing tampering to high accuracy.

Semi-Fragile Watermarking Schemes

One characteristic of the aforementioned fragile watermarking scheme is its zero tolerance to any types of changes no matter how small they are. This characteristic makes the fragile scheme unsuitable in many applications where content-preserving manipulation is necessary. In order to make efficient use of bandwidth and storage, media is often transmitted or stored in compressed formats according to some specific standards such as JPEG and MPEG. Transcoding is also a common practice to convert media from one format to another (e.g., from JPEG to TIFF). Compression and transcoding are deemed acceptable in many Internet and multimedia applications as they preserve the content. However, fragile watermarking schemes do not differentiate content-preserving operations from malicious tampering. Therefore, to meet the needs for authenticating the compressed or transcoded watermarked media, it is desirable to have semi-fragile schemes that are sensitive to malicious manipulations while tolerant to content-preserving operations.

Kundur and Hatzinakos (1999) developed a semi-fragile watermarking scheme for image authentication, which embeds the watermark by quantizing the wavelet coefficients to a predetermined degree. The scheme works as follows. They defined a quantization function $Q(f)$ as

$$Q(f) = \begin{cases} 0, & \text{if } \left\lfloor \frac{f}{\delta 2^l} \right\rfloor \text{ is even} \\ 1, & \text{if } \left\lfloor \frac{f}{\delta 2^l} \right\rfloor \text{ is odd} \end{cases} \quad (3)$$

where f stands for any coefficient, $\lfloor \cdot \rfloor$ is the floor function which returns the largest integer smaller than or equal to its argument, l is the index of the decomposition level, and d, the quantization step, is a positive integer. To watermark the image, the L-level Haar wavelet transform is performed first. Then for all the coefficients except the ones of the approximation of the image (i.e., the coefficients of the lowest-frequency subband) are subjected to the selection by using a secret key *ckey*. For each selected coefficient $f(i)$, if Equation 4 does not hold, the coefficient is adjusted according to Equation 5. Equations 4 and 5 are deined as follows:

$$Q(f(i)) = w(i) \oplus qkey(i) \quad (4)$$

where $w(i)$ is the ith bit of the watermark sequence, $qkey(i)$ is a function of the local component of the image around pixel i which returns either value 0 or 1 and is intended for increasing the security of the scheme, and $\oplus$ is the XOR operator,

$$f(i) := \begin{cases} f(i) - \delta 2^l, & \text{if } f(i) > 0 \\ f(i) + \delta 2^l, & \text{if } f(i) \le 0 \end{cases} \quad (5)$$

where the operator := stands for assignment. After the watermarking process as described above is finished, inverse Haar wavelet transform is performed on the watermarked coefficients to create the watermarked image.

As most of the existing digital image formats require that the gray level of the pixels must be an integer; when the inverse wavelet transform is applied to the watermarked coefficients, the resulting gray level of the watermarked image pixel must be rounded to integer values. However, the rounding operation may result in changing the watermark because of this tiny numerical modification. To solve this problem, Kundur and Hatzinakos (1999) chose Haar wavelet transform, exploiting the property that the coefficients at each decomposition level l are rational numbers of the form $r/2^l$ where r is an integer value. Watermarking the coefficients by using Equation 3 and adjusting the coefficients by a multiple of 2^l according to Equation 5, the gray levels of the inverse wavelet transform are guaranteed to be integers. We can also see from Equations 3 and 5 that the quantization step δ determines the degree of distortion and sensitivity of the scheme to changes in the image. A smaller value of d inflicts less significant distortion on the visual quality of the image while making the scheme less tolerant to changes.

Depending on the applications, the watermarked image may be subjected to some kind of content-preserving operations (e.g., lossy compression) before the image is transmitted through the communication channel or stored in the database. Therefore, to verify its authenticity, the received or retrieved watermarked image has to be transformed or decoded back to its spatial domain wherein the watermark extraction described as follows can take place. To extract the embedded watermark, the L-level Haar wavelet transform exactly as carried out in the embedding process is performed first. Then for all the coefficients except the ones of the approximation of the image are subjected to the selection by using a secret key *ckey*. For each selected coefficient $f(i)$, the corresponding watermark bit $\tilde{w}(i)$ is extracted according to

$$\tilde{w}(i) = Q(f(i)) \oplus qkey(i) \qquad (6)$$

A tamper assessment function (TAF) is then calculated according to

$$\mathrm{TAF}(\tilde{w}, w) = \frac{1}{N_w}\sum_{i=1}^{N_w} w(i) \oplus \tilde{w}(i) \qquad (7)$$

where w and $\tilde{w}$ are the original and extracted watermark sequences, respectively, and N_w is the length of the watermark sequences. The received/retrieved image is deemed authentic if the value of $\mathrm{TAF}(\tilde{w}, w) < T$, where $0 \le T \le 1$ is a user-defined threshold. Otherwise, the changes to the image are considered content preserving and acceptable. The value of T is application dependent. We can see that the higher its value is, the more sensitive the scheme becomes. Experiments conducted by Kundur and Hatzinakos (1999) suggest that a value of approximately 0.15 for T allows the scheme to be robust against high-quality JPEG compression and be able to detect additional tampering.

Although desirable, it is difficult to draw a clear boundary between acceptable and malicious manipulations. The designer has to bear in mind what the application is so that he/she can differentiate acceptable distortions from malicious ones.

Reversible Watermarking Schemes

One limitation of watermarking-based authentication schemes is the distortion inflicted on the host media by the embedding process. Although the distortion is often insignificant, it may not be acceptable for some applications, especially in the areas of medical imaging. Therefore, watermarking scheme capable of removing the distortion and recovering the original media after passing the authentication is desirable. Schemes with this capability are often referred to as reversible

watermarking schemes (also known as invertible [Fridrich et al., 2001] or erasable watermarking [Cox et al., 2002]). None of the algorithms mentioned previously are reversible. Usually, a reversible scheme performs some type of lossless compression operation on the host media in order to make space for hiding the compressed data and the Message Authentication Code (MAC) (e.g., hash, signature, or some other feature derived from the media) used as the watermark. To authenticate the received media, the hidden information is extracted and the compressed data is decompressed to reveal the possible original media. MAC is then derived from the possible original media. If the newly derived MAC matches the extracted one, the possible original media is deemed authentic/original. Two interesting reversible schemes are introduced as follows.

For the scheme proposed by Fridrich et al. (2001), first, the 128-bit hash of all the DCT coefficients is calculated. A number of middle-frequency coefficients are then selected from each DCT block. The least significant bits of the selected coefficients are losselessly compressed when the coefficients are scanned in a secretly determined order. The lossless compression stops when enough space has been created for embedding the hash. The compressed bit stream and the hash are then concatenated and replace the LSBs of the selected coefficients. To verify the authenticity, the verifier follows the same protocol to select the same middle-frequency coefficients in order to extract the compressed bit stream and hidden hash H from their LSBs. The extracted compressed bit stream is then decompressed and used to replace LSBs of those selected middle-frequency coefficients. The same hash function is applied to all the coefficients to obtain H'. If H' equals H, the received image is deemed authentic and the LSBs of the received image are replaced with the decompressed bit stream to yield the original. Despite its simplicity, the hash output conveys only global information about the image, that is, the signature of the image, with no local information. When a local attack is launched against the coefficients, their algorithm can only tell that the image is not authentic without being able to locate the position where the tampering occurs.

Van Leest, van der Veen, and Bruekers (2003) proposed another reversible watermarking scheme based on a transformation function that introduces "gaps" in the image histogram of image blocks. The transformation function maps the gray level of the input pixel to a unique output value so that one or two values in the range are not used, thus leaving one or two "gaps." The gaps are then used to hide the watermark. For example, a possible transformation function is one that maps the domain of [0, 1, 2, …, x, x+1, x+2, x+3, …, x'] to the range of [0, 1, 2, …, x, x+2, x+3, x+4, …, x' + 1], leaving value x+1 unmapped in the range. The scheme then embeds a "1" watermark bit by increasing the gray level of any pixel with a gray level of x by 1 to make it equal to x +1 and a "0" by not changing anything. We can see that after the embedding process is done, the gaps corresponding to gray level x+1 is partially filled and the embedding capacity is determined by the occurrences of gray level x. By allowing more gaps, higher embedding capacity can be gained at the expense of greater distortion to the visual quality. Along with some overhead information indicating the whereabouts of the gaps, the watermark verifier can extract the information and restore the original image in a bit-exact manner. Experiments demonstrated that embedding rates of approximately 0.06–0.60 bits per pixel could be achieved at PSNR levels of 45–50 dB. One drawback of this scheme is its need for the overhead information and the protocol to be hidden in the image. Moreover, a potential security loophole in the scheme is that given the fact that the computational cost for extracting the watermark is insignificant; an attacker can defeat the scheme by exhausting all the 256 possible gray level assuming that the gray level being tried is the gap.

CONCLUSION

This chapter is about the use of digital watermarking for multimedia authentication. The first section discussed the pressing needs for authenticating digital media in this information era and the two main categories of authentication techniques employed to meet these needs, namely labeling-based techniques and watermarking-based techniques. Characteristics of these two categories of techniques were compared and the reasons why watermarking is preferred in some applications were presented.

The second section identified some common attacks and classified them into content-targeting attacks and scheme-targeting attacks. How the attacks could be mounted on the media and what requirements have to be met in order to thwart those attacks were also explained.

In the third section, depending on the properties of the watermarking schemes and the desirable requirements of applications, digital watermarking schemes were broadly classified into three categories, namely fragile, semi-fragile, and reversible. Some existing schemes of each category were described in detail.

Based on the discussions made in the previous sections, it is observed that no single universal solution to all problems currently exist and is unlikely to be found in the future. The solutions are more likely to remain application dependent and the trade-offs between the conflicting requirements of low distortion, low false-positive and negative rates, and robustness to acceptable manipulations still have to be made. The authors expect that the future trends in this field are increasing the localization accuracy, identifying the type of tampering, and restoring the original media.

Section 4

Utilization and Application

This section introduces and discusses a variety of the existing applications of multimedia technologies that have influenced education, science, and even music and proposes new ways in which multimedia technologies can be implemented within organizations and in society as a whole. Within these selections, particular multimedia applications, such as face recognition technology and educational, are explored and debated. Contributions included in this section provide excellent coverage of today's multimedia environment and insight into how multimedia technologies impact the fabric of our present-day global village.

Chapter 4.1
Integrated-Services Architecture for Internet Multimedia Applications

A HISTORICAL PERSPECTIVE

The Internet has gone from near invisibility to near ubiquity and penetrated into every aspect of society in the past few years (Department of Commerce, 1998). The application scenarios have also changed dramatically and now demand a more sophisticated service model from the network. In the early 1990s, there was a large-scale experiment in sending digitized voice and video across the Internet through a packet-switched infrastructure (Braden, Clark, & Shenker, 1994). These highly visible experiments have depended upon three enabling technologies: (a) Many modern workstations now come equipped with built-in multimedia hardware, (b) IP multicasting, which was not yet generally available in commercial routers, is available, and (c) highly sophisticated digital audio and video applications have been developed. It became clear from these experiments that an important technical element of the Internet is still missing: Real-time applications often do not work well across the Internet. The Internet, as originally conceived, offers only a very simple quality-of-service (QoS), point-to-point, best-effort data delivery. However, for a real-time application, there are two aspects of the problem with using this service model. If the

sender and/or receiver are humans, they simply cannot tolerate arbitrary delays; on the other hand, if the rate at which video and audio arrive is too low, the signal becomes incomprehensible. To support real-time Internet applications, the service model must address those services that relate most directly to the time of delivery of data. Real-time applications like video and audio conferencing typically require stricter guarantees on throughput and delay. The essence of real-time service is the requirement for some service guarantees in terms of timing. In response to these demands of real-time multimedia applications, the Internet Engineering Task Force (IETF) has significantly augmented the Internet protocol stack based on the Internet integrated-services model, which is the focus of this article.

THE INTERNET INTEGRATED-SERVICES MODEL

An Internet *service model* consists of a set of service commitments; that is, in response to a service request, the network commits to deliver some service. The Internet is conventionally designed to offer a very simple service model, best effort, providing no guarantee on the correct and timely delivery of data packets. Each request to send is honored by the network *as best as it can*. This is the worst possible service: Packets are forwarded by routers solely on the basis that there is a known route, irrespective of traffic conditions along that route. This simplicity has probably been one of the main reasons for the success of IP technology. The best-effort service model, combined with an efficient transport-layer protocol (TCP [transmission-control protocol]), is perfectly suited for a large class of applications, which tolerate variable delivery rates and delays. This class of applications is called elastic applications.

However, demanding real-time applications require more sophisticated service models beyond the best effort. There has been a great deal of effort since 1990 by IETF to add a broad range of services to the Internet service model, resulting in the Internet integrated service model (Braden et al., 1994; Crowcroft, Handley, & Wakeman, 1999). The Internet integrated services model defines five classes of services that should satisfy the requirements of the vast majority of future applications.

1. *Best effort*: As described above, this is the traditional service model of the Internet.
2. *Fair*: This is an enhancement of the traditional model where there are no extra requests from the users, but the routers attempt to partition network resources in some fair manner. This is typically implemented by adopting a random-drop policy when encountering overload, possibly combined with some simple round-robin serving of different sources.
3. *Controlled load*: This is an attempt to provide a degree of service guarantee so that a network appears to the user as if there is little other traffic, and it makes no other guarantees. The admission control is usually imposed so that the performance perceived is as if the network were overengineered for those that are admitted.
4. *Predictive service*: This service gives a delay bound that is as low as possible, and at the same time, is stable enough that the receiver can estimate it.
5. *Guaranteed service*: This is where the delay perceived by a particular source or to a group is bounded within some absolute limit. This service model implies that resource reservation and admission control are key building blocks of the service.

The level of QoS provided by these enhanced QoS classes is programmable on a per-flow basis, and end-to-end QoS commitment for the data flow is built using a unified multimedia protocol stack and through resource reservation.

THE INTERNET MULTIMEDIA PROTOCOL ARCHITECTURE

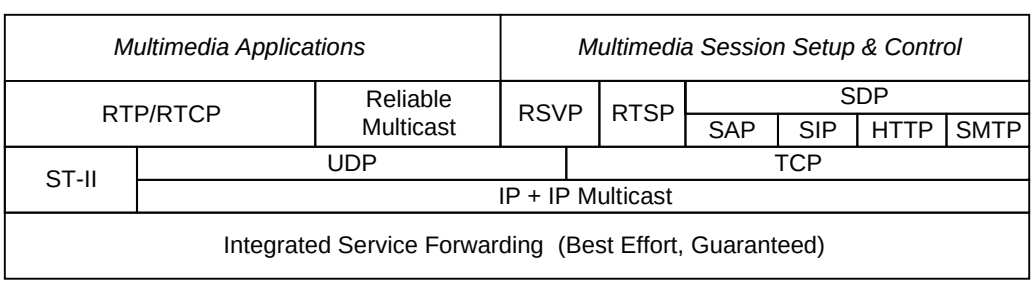
The integrated-services Internet offers a class of service models beyond the TCP/IP's (Internet protocol) best-effort service, and thus it imposes strict new requirements for a new generation of Internet protocols. The set of Internet real-time protocols, which constitute the Internet multimedia protocol architecture, represents a new style of protocols. The new style of protocols follows the proposed principles of *application-level framing* (ALF) and *integrated layer processing* (Clark & Tennenhouse, 1990). In this approach to protocol architecture, the different functions are next to each other, not on top of one another. The Internet multimedia protocol architecture is shown in Figure 1.

As shown in Figure 1, the overall multimedia data and control architecture currently incorporates a set of real-time protocols, which include the real-time transport protocol (RTP) for transporting real-time data and providing QoS feedback, the real-time streaming protocol (RTSP) for controlling delivery of streaming media, the session-announcement protocol (SAP) for advertising multimedia sessions via multicast, and the session-description protocol (SDP) for describing multimedia sessions. In addition, it includes the session-initiation protocol (SIP), which is used to invite the interested parties to join the session. But the functionality and operation of SIP does not depend on any of these protocols. Furthermore, the resource-reservation protocol (RSVP) is designed for reserving network resources. These protocols, together with reliable multicast (Handley, Floyd, Whetten, Kermode, Vicisano, & Luby, 2000), are the underlying support for Internet multimedia applications. While all the protocols above work on top of the IP protocol, the Internet stream protocol, version 2 (ST-II), is an IP-layer protocol that provides end-to-end guaranteed service across the Internet.

The Real Time Transport Protocols: RTP and RTCP

The real-time transport protocol, named as a transport protocol to emphasize that RTP is an end-to-end protocol, is designed to provide end-to-end delivery services for data with real-time characteristics, such as interactive audio and video (Schulzrinne, Casner, Frederick, & Jacobson, 2003). Those services include payload-type identification, sequence numbering, time-stamping, and delivery monitoring. Applications typically run RTP on top of UDP (user datagram protocol) to make use of its multiplexing and checksum services; both protocols contribute parts of the transport protocol functionality. However, RTP may be used with other suitable underlying network or transport protocols. RTP supports data transfer to

Figure 1. Internet protocol architecture for real time applications



nb: For the acronyms, refer to "Key Terms"

multiple destinations using multicast distribution if provided by the underlying network.

RTP consists of two closely-linked parts:

- The real-time transport protocol to carry data that has real-time properties.
- The RTP control protocol (RTCP) to monitor the quality of service and to convey information about the participants in an ongoing session. This functionality may be fully or partially subsumed by a separate session control protocol, which is beyond the scope of this document.

The RTP defines a fixed data-packet header for the set of functions required in common across all the application classes that RTP might support. However, in keeping with the ALF design principle, an extension mechanism is provided to allow the header to be tailored through modifications or additions defined in a profile specification.

RTCP control packets supplement each RTP flow and are periodically transmitted by each participant in an RTP session to all other participants. RTCP performs the following four functions.

1. Provides feedback information to application
2. Identifies RTP source
3. Controls RTCP transmission interval
4. Conveys minimal session-control information

Internet Stream Protocol: ST-II

ST-II has been developed to support efficient delivery of streams of packets to either single or multiple destinations in applications requiring guaranteed data rates and controlled delay characteristics (Schulzrinne, Rao, & Lanphier, 1998). ST-II is an Internet protocol at the same layer as IP (Figure 1). ST-II differs from IP in that every intervening ST-II entity maintains state information for each stream that passes through it. The stream state includes forwarding information, including multicast support for efficiency, and resource information, which allows network or link bandwidth and queues to be assigned to a specific stream. This preallocation of resources allows data packets to be forwarded with low delay, low overhead, and a low probability of loss due to congestion, and thus to support efficient delivery of streams of packets to either single or multiple destinations in applications requiring guaranteed data rates and controlled delay characteristics.

Protocols for Multimedia Session Setup and Control

There are two basic forms of multimedia session-setup mechanisms. These are session advertisement and session invitation. Session advertisements are provided using a session directory, and session invitation (inviting a user to join a session) is provided using a session-invitation protocol such as SIP or packet-based multimedia communication systems standard H.323 (ITU, 1998).

Before a session can be advertised, it must be described using the session-description protocol. SDP describes the content and format of a multimedia session, and the session-announcement protocol is used to distribute it to all potential session recipients.

The Session-Description Protocol

The session-description protocol is used for general real-time multimedia session-description purposes and is purely a format for session description (Handley & Jacobson, 1998). SDP is intended for using different transport protocols as appropriate.

SDP serves two primary purposes. It is a means to communicate the existence of a session, and is a means to convey sufficient information to enable joining and participating in the session. A session description contains the following information.

- Session name and purpose
- The media comprising the session, such as the type of media (video, audio), the transport protocol (RTP/UDP/IP, H.320), and the format of the media (H.261 video, MPEG video)
- Time(s) the session is active.
- Information for receiving those media (addresses, ports, formats, and so on)

The SDP description is announced using the session-announcement protocol.

Session-Announcement Protocol

SAP defines an announcement protocol to be used to assist the advertisement of multicast multimedia conferences and other multicast sessions, and to communicate the relevant session-setup information to prospective participants (Handley, Perkins, & Whelan, 2000). Sessions are described using the session-description protocol, and the session description is the payload of the SAP packet.

SAP supports session announcement and deletion. However, SAP defines no rendezvous mechanism, the SAP announcer is not aware of the presence or absence of any SAP listeners, and no additional reliability is provided over the standard best-effort UDP/IP semantics. A SAP announcer periodically sends an announcement packet to a well-known multicast address and port. A preannounced session can be modified by simply announcing the modified session description. A previously announced session may be deleted.

The announcement contains an authentication header for verifying that changes to a session description or deletion of a session are permitted. It can also be used to authenticate the identity of the session creator.

Session-Initiation Protocol

Not all sessions are advertised, and even those that are advertised may require a mechanism to explicitly invite a user to join a session. The session-initiation protocol is an application-layer control (signaling) protocol that can establish, modify, and terminate multimedia sessions or calls (Rosenberg et al., 2002). SIP can also invite participants to already existing sessions, such as multicast conferences. Media can be added to (and removed from) an existing session. SIP invitations used to create sessions carry session descriptions that allow participants to agree on a set of compatible media types. SIP runs on top of several different transport protocols.

SIP supports five aspects of establishing and terminating multimedia sessions.

- **User location:** Determination of the end system to be used for communication
- **User availability:** Determination of the willingness of the called party to engage in communications
- **User capabilities:** Determination of the media and media parameters to be used
- **Session setup:** "Ringing," establishment of session parameters at both the called and calling party
- **Session management:** Including transferring and terminating sessions, modifying session parameters, and invoking services

Note that SIP is not a vertically integrated communications system. SIP is, rather, a component that can be used with other Internet protocols to build a complete multimedia architecture (e.g., RTP, RTSP).

Controlling Multimedia Servers: RTSP

A standard way to remotely control multimedia streams delivered, for example, via RTP, is the real-time stream-control protocol. Control includes absolute positioning within the media stream, recording, and possibly device control. RSTP is primarily aimed at Web-based media-on-demand

services, but it is also well suited to provide VCR-like controls for audio and video streams, and to provide playback and record functionality of RTP data streams. A client can specify that an RTSP server plays a recorded multimedia session into an existing multicast-based conference, or can specify that the server should join the conference and record it. RTSP acts as a "network remote control" for multimedia servers.

The protocol supports retrieval of media from media servers, the invitation of a media server to a conference, and the addition of media to an existing presentation.

Resource Reservation Protocol

RSVP is an IP resource-reservation setup protocol designed for an integrated-services Internet, and it provides receiver-initiated setup of resource reservations for multicast or unicast data flows that take a significant fraction of the network resources (Braden, Zhang, Berson, Herzog, & Jamin, 1997). Using RSVP, the resources necessary for a multimedia session are reserved, and if no sufficient resource is available, the admission is rejected. The reservations and route setups apply only to packets of a particular session, and RSVP identifies a particular session by the combination of destination address, transport-layer protocol type, and destination port number.

RSVP makes receivers responsible for requesting a specific QoS. A QoS request from a receiver host application is passed to the local RSVP process. The RSVP then carries the request to all the nodes (routers and hosts) along the reverse data path(s) to the data source(s), but only as far as the router where the receiver's data path joins the multicast distribution tree.

Quality of service for a particular data flow is ensured by mechanisms collectively called *traffic control*, and they are a packet classifier, admission control, and "packet scheduler," or some other link-layer-dependent mechanism to determine when particular packets are forwarded.

During reservation setup, an RSVP QoS request undergoes *admission control* and *policy control*. Admission control determines whether the node has sufficient available resources to supply the requested QoS. Policy control determines whether the user has administrative permission to make the reservation.

RSVP does not transport application data, but is rather an Internet control protocol. It uses underlying routing protocols to determine where it should carry reservation requests. As routing paths change, RSVP adapts its reservation to new paths if reservations are in place.

THE FUTURE TRENDS

Technically, there are several types of communication networks that are used to provide multimedia communication services, which include data networks, broadband television networks, integrated-services digital networks, and broadband multiservice networks. The Internet is the most widely deployed data network, and significant advancement has been made to provide communication services beyond its original design. This advancement is centered on QoS provisioning on the Internet so that QoS-sensible applications can be supported across the Internet.

Generally, work on QoS-enabled Internet has led to two distinct approaches: (a) the integrated services architecture (often called *Intserv*) and its accompanying signaling protocol, most importantly, RSVP, and (b) the differentiated services architecture (often called *Diffserv*).

As described in this article, the Internet integrated-services architecture is an extension of the Internet architecture and protocols to provide integrated services, that is, to support real-time as well as the current non-real-time service of IP. This extension is necessary to meet the growing need for real-time service for a variety of new applications, including teleconferencing, remote seminars, telescience, and distributed simulation.

It allows sources and receivers to exchange signaling messages that establish packet classification and forwarding state on each node along the path between them. In the absence of state aggregation, the amount of state on each node scales in proportion to the number of concurrent reservations, which can be potentially large on high-speed links. Integrated services are considered not scalable and best suited in intranet and LAN (local area network) environments.

In the last few years, we have witnessed the development of other models of service differentiation in order to facilitate the deployment of real-time applications, including the differentiated-services architecture, relative priority marking, service marking, label switching, and static per-hop classification. The differentiated-services architecture has received the most attention in the Internet community.

In contrast to integrated services, which use the more stringent and complex quality-of-service approach, the differentiated-services architecture has emerged as an alternative for implementing scalable service differentiation on the Internet. This architecture achieves scalability by aggregating traffic classification states, which are conveyed by means of IP-layer packet marking. Packets are classified and marked to receive a particular per-hop forwarding behavior on nodes along their path. Sophisticated classification, marking, policing, and shaping operations need only be implemented at network boundaries or hosts. Network resources are allocated to traffic streams by service-provisioning policies that govern how traffic is marked and conditioned upon entry to a differentiated-services-capable network, and how that traffic is forwarded within that network. A wide variety of services can be implemented on top of these building blocks (Blake, Black, Carlson, Davies, Wang, & Weiss, 1998). We can foresee that in the future, support for multimedia applications on the Internet, both integrated services and differentiated services, will be developed and deployed, and will complement each other.

CONCLUSION

The Internet has evolved from a provider of simple TCP/IP best-effort service to an emerging integrated-service Internet. This development provides tremendous opportunities for building real-time multimedia applications over the Internet. The protocol stack necessary for classes of quality of service, including real-time applications, is presented as the Internet integrated-service architecture that supports the various service models. The constituent real-time protocols of this architecture are the foundations and the critical support elements for the building of Internet real-time multimedia applications.

KEY TERMS

Elastic applications: A kind of network applications that will always wait for data to arrive rather than proceed without it.

HTTP: Short for *hypertext transfer protocol,* the underlying protocol used by the World Wide Web.

IP: Abbreviation of *Internet protocol.* IP specifies the format of packets, also called datagrams, and the addressing scheme. Most networks combine IP with a higher level protocol called transmission-control protocol (TCP), forming TCP/IP networks.

Multicast: Means transmitting a single message to a select group of recipients. A simple example of multicasting is sending an e-mail message to a mailing list.

Protocol: A set of rules that govern the operation of functional units to achieve communication.

Protocol architecture: An organization structure of the communication system, which comprises constituent protocols and the relationships among them.

Real-time applications: One class of applications needs the data in each packet by a certain time, and if the data has not arrived by then, the data is essentially worthless.

RSVP: The Internet standard protocol *resource-reservation protocol* (RSVP).

RTP/RTCP: The Internet standard *real-time transport protocol* (RTP) and *RTP control protocol* (RTCP).

RTSP: The Internet standard *real-time streaming protocol* (RTSP) for controlling delivery of streaming of multimedia data.

SAP: The Internet standard *session-announcement protocol* (SAP) for advertising multimedia sessions via multicast.

SDP: The Internet standard *session-description protocol* (SDP) is used for general real-time multimedia session-description purposes and is purely a format for session description.

Service model: Consists of a set of service commitments. In response to a service request, the network commits to deliver some service.

SIP: The Internet standard *session-initiation protocol* (SIP), a signaling protocol for Internet conferencing, telephony, presence, events notification, and instant messaging.

SMTP: Short for *simple mail-transfer protocol*, a protocol for sending e-mail messages between servers. Most e-mail systems that send mail over the Internet use SMTP to send messages from one server to another. In addition, SMTP is generally used to send messages from a mail client to a mail server.

ST-II: The Internet *stream protocol, version 2* (ST-II), an IP-layer protocol that provides end-to-end guaranteed service across the Internet.

TCP: Abbreviation of *transmission-control protocol*, one of the main protocols in TCP/IP networks. Whereas the IP protocol deals only with packets, TCP enables two hosts to establish a connection and exchange streams of data.

UDP: Abbreviation for *user datagram protocol*, a connectionless protocol that, like TCP, runs on top of IP networks. Unlike TCP/IP, UDP/IP provides very few error-recovery services so is less reliable than TCP, offering instead a direct way to send and receive datagrams over an IP network.

Chapter 4.2
Location-Based Multimedia Content Delivery System for Monitoring Purposes

Athanasios-Dimitrios Sotiriou

Panagiotis Kalliaras
National Technical University of Athens, Greece

INTRODUCTION

Advances in mobile communications enable the development and support of real-time multimedia services and applications. These can be mainly characterized by the personalization of the service content and its dependency to the actual location within the operational environment. Implementation of such services does not only call for increased communication efficiency and processing power, but also requires the deployment of more intelligent decision methodologies.

While legacy systems are based on stationary cameras and operational centers, advanced monitoring systems should be capable of operating in highly mobile, ad-hoc configurations, where overall situation and users roles can rapidly change both in time and space, exploiting the advances in both the wireless network infrastructure and the user terminals' capabilities. However, as the information load is increased, an important aspect is its filtering. Thus, the development of an efficient rapid decision system, which will be flexible enough to control the information flow according to the rapidly changing environmental conditions and criteria, is required. Furthermore, such a system should interface and utilize the underlying network infrastructures for providing the desired quality of service (QoS) in an efficient manner.

In this framework, this article presents a *location-based multimedia content delivery system* (LMCDS) for monitoring purposes, which incorporates media processing with a decision support system and positioning techniques for providing the appropriate content to the most suitable users, in respect to user profile and location, for monitoring purposes. This system is based on agent technology (Hagen & Magendanz, 1998) and aims to promote the social welfare, by increasing

the overall situation awareness and efficiency in emergency cases and in areas of high importance. Such a system can be exploited in many operational (public or commercial) environments and offers increased security at a low cost.

SERVICES

The LMCDS provides a platform for rapid and easy set up of a monitoring system in any environment, without any network configurations or time-consuming structural planning. The cameras can be installed in an ad hoc way, and video can be transmitted to and from heterogeneous devices using an intelligent decision support system (IDSS) according to the user's profile data, location information, and network capabilities.

Users can dynamically install ad-hoc cameras to areas where the fixed camera network does not provide adequate information. The real-time transmission of still images or video in an emergency situation or accident to the available operational centers can instantly provide the necessary elements for the immediate evaluation of the situation and the deployment of the appropriate emergency forces. This allows the structure of the monitoring system to dynamically change according to on-the-spot needs.

The IDSS is responsible for overviewing the system's activity and providing multimedia content to the appropriate users. Its functionality lies in the following actions:

- Identifying the appropriate user or group of users that need access to the multimedia content (either through user profile criteria or topological criteria).
- Providing the appropriate multimedia content in relevance to the situation and the location.
- Adapting the content to the user's needs due to the heterogeneity of the users devices—that is, low bit rate video to users with portable devices.

The LMCDS can evaluate users' needs and crisis events in respect to the topological taxonomy of all users and provide multimedia content along with geographical data. The location information is obtained through GPS or from GPRS through the use of corresponding techniques (Markoulidakis, Desiniotis, & Kypris, 2004). It also provides intelligent methodologies for processing the video and image content according to network congestion status and terminal devices. It can handle the necessary monitoring management mechanisms, which enable the selection of the non-congested network elements for transferring the appropriate services (i.e., video streaming, images, etc.) to the concerned users. It also delivers the service content in the most appropriate format, thus allowing the cooperation of users equipped with different types of terminal devices.

Moreover, the LMCDS provides notification services between users of the system for instant communication in case of emergency through text messaging or live video feed.

All of the above services outline the requirements for an advanced monitoring system. The LMCDS functionality meets these requirements, since it performs the following features:

- Location-based management of the multimedia content in order to serve the appropriate users.
- Differentiated multimedia content that can be transmitted to a wide range of devices and over different networks.
- Lightweight codecs and decoders that can be supported by devices of different processing and network capabilities.
- IP-based services in order to be transparent to the underlying network technology and utilize already available hardware and operating systems platforms.
- Intelligent delivery of the multimedia content through the LMCDS in order to avoid increased traffic payload as well as information overload.

- Diverse localization capabilities through both GPS and GPRS, and generation of appropriate topological data (i.e., maps) in order to aid users.

However, the system architecture enables the incorporation of additional location techniques (such as WLAN positioning mechanisms) through the appropriate, but simple, development of the necessary interfaces with external location mechanisms.

In order to describe the above services in a more practical way, a short list of available options and capabilities of the system is given below. The target group of the LMCDS consists of small to medium businesses that seek a low-cost solution for monitoring systems or bigger corporations that need an ad hoc extension to their current system for emergency cases and in order to enhance their system's mobility. Even though the users of the system consist mainly of security staff and trained personnel that are in charge of security, the system's ease of use, low user complexity, and device diversity allow access even to common untrained users.

The system offers a range of capabilities, most of which are summarized in Figure 1, such as:

- User registration and authentication.
- User profile (i.e., device, network interface).
- Location awareness:
  - User is located through positioning techniques.
  - User is presented with appropriate topographical information and metadata.
  - User is aware of all other users' locations.
  - User can be informed and directed from a Center of Security (CS) to specified locations.
- Multimedia content:
  - Video, images, and text are transmitted to user in real time or off-line based on situation or topological criteria.

Figure 1. System functionality and services

  - User can provide feedback from his device through camera (laptop, PDA, smart phone) or via text input.
  - Content is distributed among users from the CS as needed.
- Ad hoc installation of cameras that transmit video to CS and can take advantage of wireless technology (no fixed network needed).
- Autonomous nature of users due to agent technology used.

LMCDS ARCHITECTURE

The LMCDS is designed to distribute system functionality and to allow diverse components to work independently while a mass amount of information is exchanged. This design ensures that new users and services can be added in an ad hoc manner, ensuring future enhancements and allowing it to support existing monitoring systems.

Multi-agent systems (MASs) (Nwana & Ndumu, 1999) provide an ideal mechanism for implementing such a heterogeneous and sophisticated distributed system in contrast to traditional software technologies' limitations in communication and autonomy.

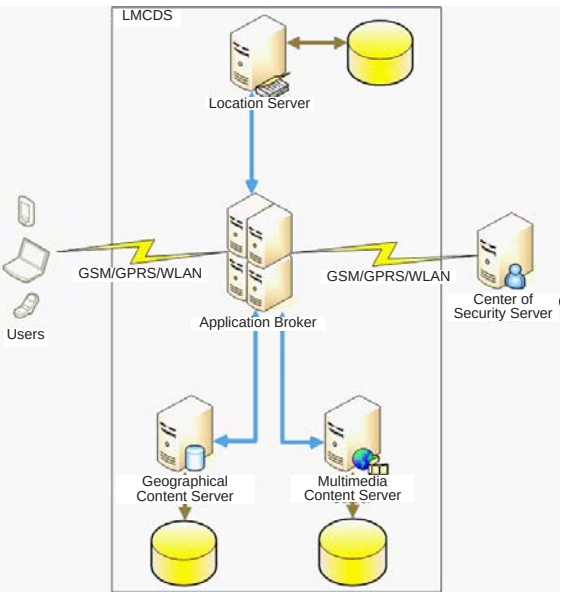
The system is developed based on MAS and allows diversified agents to communicate with each other in an autonomous manner, resulting in an open, decentralized platform. Tasks are being delegated among different components based on specific rules, which relate to the role undertaken by each agent, and information is being composed to messages and exchanged using FIPA ACL (FIPA, 2002a). An important aspect for the communication model is the definition of the content language (FIPA, 2002b). Since LMCDS targets to a variety of devices, including lightweight terminals, the LEAP language (Berger, Rusitschka, Toropov, Watzke, & Schlichte, 2002) of the JADE technology has been exploited.

In addition to the security mechanisms supported by the underlying network components, the JADE platform offers a security model (Poggi, Rimassa, & Tomaiuolo, 2001) that enables the delegation of tasks to respective agent components by defining certificates, and ensures the authentication and encryption of TCP connections through the secure socket layer (SSL) protocol (http://www.openssl.org/).

The general architecture of the LMCDS is shown in Figure 2. The platform is composed of different agents offering services to the system which are linked by an application broker agent, acting as the coordinator of the system. These agents are the location server, the center of security server, the application broker, the geographical content server, and the multimedia content server. The latter two are discussed in later sections in more detail, while a brief description of the functionality of the others is given as follows.

The location server agent is responsible for the tracking of all users and the forwarding of location-based information to other components. The information is gathered dynamically and

Figure 2. Architecture overview



kept up-to-date according to specific intervals. The intelligence lies in the finding of the closest users to the demanded area, not only in terms of geographical coordinates, but also in terms of the topology of the environment. More information on location determination is given in a following section.

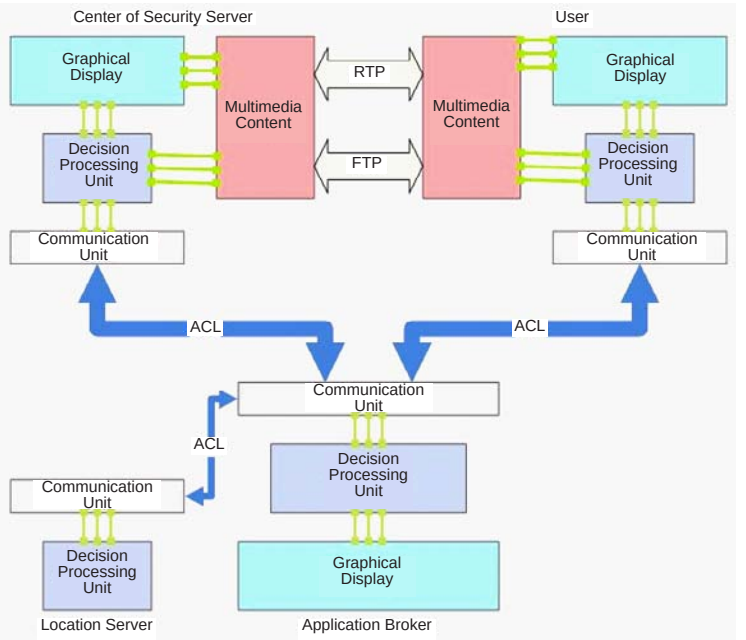
The center of security server agent monitors all users and directs information and multimedia content to the appropriate users. It is responsible for notifying users in emergency situations, and also performs monitoring functions for the system and its underlying network.

The User agent components manage information, including the transmission and reception of image or video, the display of location information, critical data, or other kinds of displays. They are in charge of several user tasks, such as updating users' preferences and location, decoding the response messages from the application broker, and performing service level agreement (SLA) (ADAMANT, 2003) monitoring functionalities. The user agent can reside in a range of devices, since it is Java based.

Finally, the application broker agent acts as a mediator that provides the interface between all of the components. It is responsible for prioritizing user requests according to users' profiles, performing authentication functions, and acting as a facilitator for SLA negotiations. It also coordinates the communication process between users in order for the multimedia content to be delivered in the appropriate format according to the user's processing and network capabilities, and also the network's payload.

A closer look into the components of each agent, along with the interaction between them, is shown in Figure 3. Each agent is composed of three main components: the graphical display, which is responsible for user input and information display; the communication unit, in charge of agent communication through ACL messages; and the decision processing unit, which processes all received information. In addition, the user and the CS include a multimedia content component

Figure 3. Agent components



for the capture, playback, and transmission of multimedia data through RTP or FTP channels.

MULTIMEDIA PROCESSING AND ENCODING

Video/Image Formats

One of the novelties is the ability of the system to perform real-time format conversions of the image or video data and transmit to several heterogeneous recipients, ranging from large PC servers to small personal devices like PDAs or mobile phones.

The LMCDS enables the adoption and support of different video formats, according to the partial requirements of the user terminals and the available networks status. The most commonly used is the M-JPEG (http://www.jpeg .org/index.html) format. It was preferred over other common video formats suitable for wireless networks like MPEG (http://www. m4if.org/) and H.263 (http://www.itu.int/rec/recommendation.asp), which provide higher compression ratio, because using them can require intense processing power both for the encoder and the decoder. Also, frames in MPEG or H.263 streams are inter-related, so a single packet loss during transmission may degrade video quality noticeably. On the contrary, M-JPEG is independent of such cascaded-like phenomena, and it is preferable for photo-video application temporal compression requirements for smoothness of motion.

It is a lossy codec, but the compression level can be set at any desired quality, so the image degradation can be minimal. Also, at small data rates (5-20Kbps) and small frame rates, M-JPEG produces better results than MPEG or H.263. This is important, as the photos or video can be used as clues in legal procedures afterwards, where image quality is more crucial than smooth motion. Another offering feature is the easy extraction of JPEG (http://www.jpeg .org/index.html) images from video frames.

The video resolution can be set in any industry-standard (i.e., subQCIF) or any other resolution of width and height dividable of 8, so the track is suitable for the device it is intended for. Video is streamed directly from the camera-equipped terminals in a peer-to-peer manner. Transmission rates for the video depend on the resolution and the frame rate used. Some sample rates are given in Table 1.

Apart from M-JPEG, another set of video formats have been adopted, such as H263 and MPEG-4. The development of these formats enables the testing and evaluation of the LMCDS, based on the network congestion and the current efficiency of the supported video formats and the crisis situations in progress. This means that for a specific application scenario, the encoding with M-JPEG format can lead to better quality on the user terminal side, while the MPEG 4 format can be effective in cases that the network infrastructure is highly loaded, so the variance in bit rate can keep the quality in high values.

Image compression is JPEG with resolution of any width and height dividable of 8. For the real-time transmission of video stream, the real-time transfer protocol (RTP, http://www.ietf.org/rfc/rfc3550.txt) is used, while for stored images and video tracks, the file transfer protocol (FTP) is used.

Table 1. Output video formats for the application

Resolution	Frame Rate	Suitable Network	Trans. Rate (kbps)	Target Device
160 x 120	1	GPRS WLAN	2 – 3	Smartphone PDA, PC
160 x 120	5	GPRS WLAN	10 – 15	Smartphone, PDA,PC
232 x 176	2	GPRS WLAN	10 – 15	PDA,PC
320 x 240	5	WLAN	30 – 40	PC
320 x 240	15	WLAN	90 – 120	PC
640 x 480	5	WLAN	45 – 55	PC

Video Processing

It is important to point out that the output video formats can be produced and transmitted simultaneously with the use of the algorithm shown in Figure 4.

Note that the image/video generator can be called several times for the same captured video stream as long as it is fed with video frames from the frame grabber. So, a single user can generate multiple live video streams with variations, not only in frame rate and size, but also in JPEG compression quality, color depth, and even superimpose layers with handmade drawings or text. The algorithm was implemented in Java with the use of the JMF API (http://java.sun.com/products/java-media/jmf/).

For a captured stream at a frame rate of n frames per second, the frame grabber component extracts from the raw video byte stream n/A samples per second, where A is a constant representing the processing power of the capturing device. Depending on how many different qualities of video streams need to be generated, m Image/Video Generator processes are activated, and each process i handles K_i fps. The following relationship needs to be applied:

$$K_i = B_i * n / A * m \text{ , where}$$

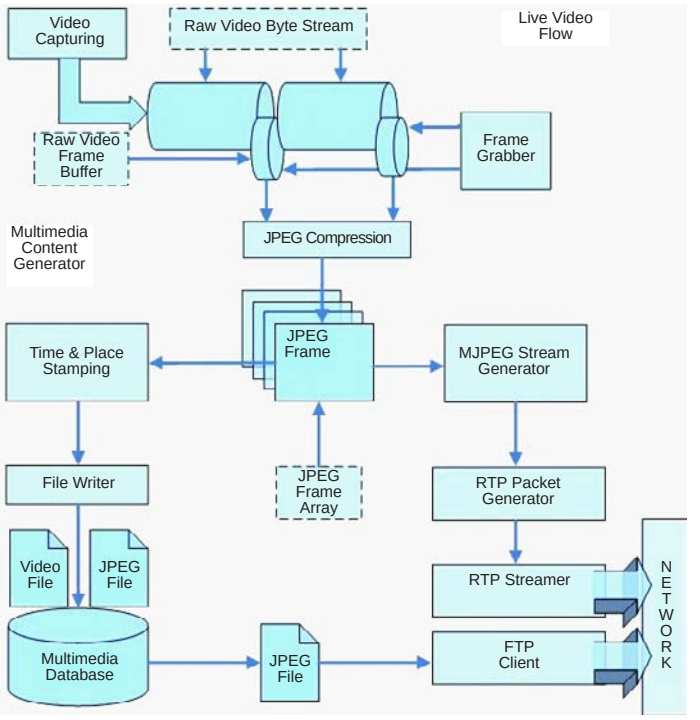
$$B_i = (K_i * A * m) / n \text{ and}$$

$$\sum B_i = m$$

There is also a latency of $m*C_i$ seconds per video stream, where C_i depends on the transcoding time of the image to each final format.

So, this tendency of the LMCDS to keep the frame rate low is inevitable due to this sampling process. However, using low frame rates is quite common in surveillance systems. It also allows long hours of recording, where video size is optimal when minimum both for storage and transmission, and is less demanding in process-

Figure 4. LMCDS video processing overview



ing power for use with video players running on small devices.

GEOGRAPHICAL CONTENT DELIVERY

Positioning Methods

The LMCDS uses the following techniques for locating the users' positions inside the served environment.

- *GPS (Global Positioning System)* is a global satellite system based on a group of non-geostatic satellites in middle altitude orbit (12,000 miles). The GPS-enabled devices have the ability to locate their position with a high degree of accuracy by receiving signals from at least six satellites.
- A GSM/GPRS subscriber can be located upon request, depending on the received power from adjacent cells. More information about these mechanisms can be found in Markoulidakis et al. (2004).
- The *Ekahau* position engine (http://www.ekahau.com/pdf/EPE_2.1_datasheet.PDF) is designed to locate 802.11b (at present) wireless LAN users positions in the indoor environment. In the context of radio resource management, the software could apply the access point's radio coverage map in the indoor environment. It uses a calibration method. Initially it measures a set of sample points' radio strength. Based on these sample points, the engine can estimate a client WLAN station's approximate location, given an arbitrary combination of signal strengths.

Geographical Database

The geographical database of the LMCDS is storing information about the positions of the users that are registered in the system. The information is obtained regularly by scheduled queries. When the users perform service request messages to the system, their position coordinates are automatically retrieved (through any of the above methods), so their location in the geographical DB is also updated. Special importance has been given to the ability of the system to serve queries about the relative position of its users and estimation of distances. So, the scheduled queries can be of the following types:

- Find my 3 nearest users and send them a video.
- Estimate the time that I need to get to Building A.
- Find the users closest to point B and send pictures to those that operate in GPRS network and high-quality video to those in UMTS or WLAN.
- When user C enters a specified area, send him a message.

The user is displayed visual information in the form of maps to its device. The map consists of raster data—that is, the plan of the area and also several layers of metadata, showing points of interest, paths, as well as the position of relative users.

FUTURE TRENDS

Future steps involve the exploitation of video streaming measurements for providing guaranteed QoS of the video content to the end user, as well as the better utilization of the available radio resources. Furthermore, the incorporation of new trends in video streaming in conjunction with a markup language for multimedia content, such as MPEG-7 or MPEG-21, can offer a higher level of personalized location-based services to the end user and are in consideration for future development.

CONCLUSION

This article presented a location-based multimedia content system enabling real-time transfer of multimedia content to end users for location-based services. Based on the general architecture of multi-agent systems, it focused on fundamental features that enable the personalization of the service content and the intelligent selection of the appropriate users for delivering the selected content.

KEY TERMS

Agent: A program that performs some information gathering or processing task in the background. Typically, an agent is given a very small and well-defined task.

Application Broker: A central component that helps build asynchronous, loosely coupled applications in which independent components work together to accomplish a task. Its main purpose is to forward service requests to the appropriate components.

IDSS: Intelligent decision support system.

LMCDS: Location-based multimedia content delivery system.

MAS: Multi-agent system.

Media Processing: Digital manipulation of a multimedia stream in order to change its core characteristics, such as quality, size, format, and so forth.

Positioning Method: One of several methods and techniques for locating the exact or relative geographical position of an entity, such as a person or a device.

INTRODUCTION

With the opening of the telecommunication market and the emergence of low-cost and heterogeneous wireless access technologies, it is envisaged that next-generation network and service providers will not only vary in the deployed access technology but also in their business models and structures. Such providers will differ from large providers such as the current telecom providers offering multiple services and covering large geographical areas, down to small providers offering certain services such as conferencing or messaging only or covering small geographical areas such as a coffee shop or a shopping mall. Further, while in the current networking environment, a home provider of a user is usually represented by a large telecom provider; in such a heterogeneous environment, any trustworthy entity such as an application provider, a banking entity, or a credit card provider that is capable of authenticating the user and marinating his usage profile can act as a home provider. Towards this vision this article discusses the issues that concern the establishment of multimedia applications across heterogeneous networks.

NEXT-GENERATION NETWORKS AND THE ALL-IP CONVERGENCE

Convergence of heterogeneous wireless technologies over a broadband IP core network will allow mobile subscribers to access a new variety of services, over a variety of access networks and by using a variety of devices. This integration will be realized on the network access with devices able to hand off across heterogeneous wireless access technologies, service delivery, and availability (Dagiuklas & Velentzas, 2003). There is no industry consensus on what next-generation networks will look like but, as far as the next-generation networks are concerned, ideas and concepts include:

- Transition to an "All-IP" network infrastructure
- Support of heterogeneous access technologies (e.g., UTRAN, WLANs, WiMAX, xDSL, etc.)
- VoIP substitution of the pure voice circuit switching
- Seamless handovers across both homogeneous and heterogeneous wireless technologies
- Mobility, nomadicity, and QoS support on or above the IP layer
- Provisioning of triple-play services creating a service bundle of unifying video, voice, and Internet
- Home networks opening new doors to the telecommunication sector and network providers
- Unified control architecture to manage application and services
- Convergence among network and services.

HETEROGENEOUS MULTIMEDIA NETWORKS AND SERVICES

Vision

In order to allow seamless communication and roaming in a heterogeneous wireless environment, one needs to provide an efficient way for coupling multimedia service provisioning, access with fast-handover schemes, and establishing trust relations among service providers and users. This necessitates the provisioning of a framework for establishing security and trust relations among network operators, service providers, and mobile users, allowing thereby smooth roaming among different administrative domains/networks and seamless provisioning of multimedia services. Such a vision infrastructure is illustrated in Figure 1.

This infrastructure will support the dynamic establishment of trust relations between independent providers (e.g., foreign and home providers) in a distributed manner over hybrid IPv4 and IPv6 networks (Salkintzis, 2004). Moreover, it will provide the required enhancements for providing secure interconnection among different heterogeneous networks, establishing user-provider trust relations, and the necessary means for authenticating users in foreign domains and exchanging their profiles in a secure manner. This would thereby enable users to roam to foreign networks and use the provided services in these networks without affecting their privacy. Finally, to support the smooth and fast handover, efficient and secure context exchange mechanisms will be provided, allowing users to roam among different providers without having to explicitly re-authenticate themselves and establish new trust relations.

It is envisioned that the NGN architecture will be based on packet-based technologies. The most important part of NGN is the division of network functionality into many distributed functions, which fall into the following categories (Dagiuklas et al., 2005):

Figure 1. Inter-domain framework

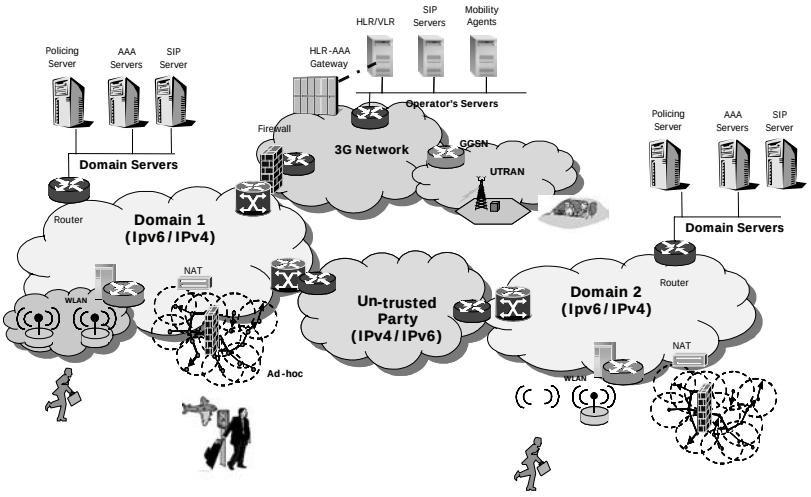

Figure 2. NGN architecture migration (Nokia, 2001)

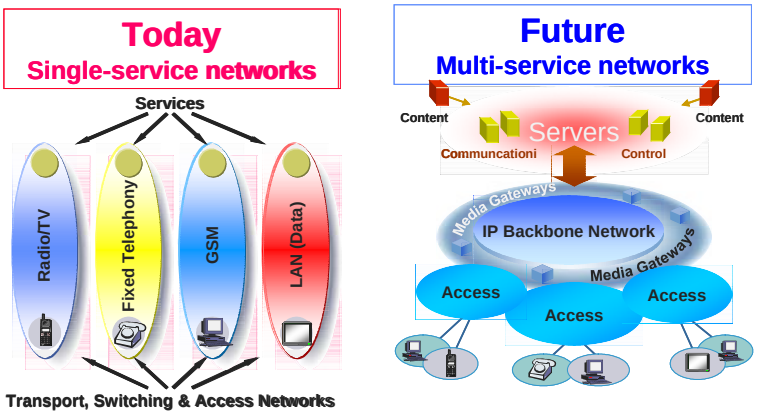


1. Control, management, and signaling, which provides the intelligence needed for user control of the connection. This intelligence is distributed.
2. Access, routing, switching, and transport, which provides the functions needed for transporting information between end users and other network elements.
3. Convergence with existing legacy networks (PSTN, SS7, mobile networks).

Figure 2 illustrates the transitions from the current scene towards NGN.

To achieve the goal of enabling flexible roaming between different network and services providers in a secure and chargeable manner between providers of different technologies and business models, this article will be addressing the following requirements (Velentzas & Dagiuklas, 2005):

- Secure and scalable inter-domain AAA infrastructure for mobile user (secure roaming)
- User access security
- Application level security

- Concepts for security context transfer while the user hands over among heterogeneous wireless technologies.

INTER-PROVIDER RELATIONSHIP

The establishment of heterogeneous networks aims to import substantial services for the customer through the specification and realizing of infrastructure that enable dynamic trust relation among different providers in a secure and scalable manner. Particular emphasis should be given to roaming business models while the mobile users move across different administrative domains. The possibly very large number of service and network providers as well as home providers makes the establishment of static trust relations between all of those providers tedious and non-economical. Therefore, mechanisms and solutions must be defined that will allow users to roam from one provider (either network operator or service provider or a mixture of both) to the other without having to explicitly subscribe to the services of each provider or assuming some pre-established trust relation between the different providers.

Dynamic Trust Relations

Most current solutions for enabling roaming of users among different network providers assume the existence of pre-established trust relations between the involved partners. Two providers that would like to enable user roaming must be registered at this broker. Currently, the number of network providers is relatively small, with those providers having a large scale in terms of the number of supported users and covered geographical area. Further, the definition of a home provider might change as well, allowing for example a banking unit to act as the home provider of a user and authenticate his identity. Registering all possible providers at a single trust broker would surely not scale. This would then lead to having different brokers each maintaining trust relations to only a small number of providers. To allow for roaming between any two entities, the foreign network needs to be able to discover the home provider of the user and which trust brokers could be used for establishing a trust relation with the home provider. The experience gained for private key distribution architectures shows that for such schemes to work, they need to be distributed. The work to be done here would include specifying a distributed trust infrastructure and investigating its applicability and performance with the increasing number of providers in NGN.

Identity Management

Identity management is best defined as "those IT and business processes, organizations, and technologies that are applied to ensure the integrity and privacy of identity and how it translates to access." This results in its effective use as a crucial element of IT security infrastructure. Recently, identity management has been elevated within many IT organizations to be a formal program consideration by several business drivers.

The Liberty framework, developed by the Liberty Alliance project (www.projectliberty.org), comprises an identity management architecture focused on the establishment of secure, consistent, and manageable business relationships and interactions over the Internet. This architecture is realized along circles of trusts embracing affiliated identity providers and service providers. The Liberty framework further defines adequate schemas and metadata for identity management, along with the required bindings to Web-based middleware (SOAP) services.

Current roaming solutions require close interaction between the home and foreign providers in order to gain access to user identity profiles. 3GPP solutions necessitate for example that any signaling messages sent by the user be routed through the home network. This not only increases the set-up delay for establishment of communication

sessions, but also complicates the offering of local services in foreign networks. To overcome this problem the home and foreign networks need to be able to exchange user profiles that allow the foreign network to make the decision of whether or not to grant a user access to certain services locally. However, while doing this the privacy of the user's data and profile need to be guaranteed, and the foreign provider should only be given information that is needed for authorizing the user and providing him with the necessary access rights.

Policy-Driven, Configurable, and Programmable AAA Infrastructures

The exact behavior of AAA infrastructure might vary considerably depending on its location (intra- or inter-domain), functionality (broker, proxy, home, or foreign), supported features (QoS, mobility, multimedia), provider policy, load balancing architectures, or security requirements for example. To ease the replacement of RADIUS protocol-based servers to diameter-based AAA servers, server and network providers need to have powerful and yet simple interfaces for programming and customizing those servers (Nakhjiri & Nakhjiri, 2005). While Diameter-based AAA technologies are increasingly being considered as the basis for AAA in NGN, there will always be providers relying on proprietary or older solutions. To still be able to communicate with such providers and exchange AAA information with them, some translation mechanisms need to be used to cover the gap.

Reliable and Secure Intra- and Inter-Provider AAA Infrastructure

While attacking a certain server of access router by generating a lot of useless traffic might render part of the network or a certain service useless, attacking the AAA infrastructure would render the complete network useless. Mounting an attack on a trust broker would make any roaming between the networks impossible. Currently, the AAA infrastructure in PSTN networks is not very vulnerable simply because the end systems that are allowed to connect to the network are "dumb." However, in the open environment of NGN mounting attacks on an AAA server will become easier. Any system can start a large number of authentication requests and occupy thereby not only a substantial share of the network bandwidth but also of the processing resources available to the AAA servers.

Another aspect to be considered here is the reliability of the AAA infrastructure in the face of various failure situations such as software or hardware failures of the AAA servers themselves or the links connecting those servers to the networks. The following points need to be dealt with in future work:

- Identification of attack and exploitation possibilities on AAA infrastructures
- Dynamic detection of attacks on AAA infrastructure and devising of mechanisms for defending and protecting against those attacks and reducing their effects
- Specification and realization of fail-over mechanisms for AAA servers

Secure Multimedia Service Access

In the literature of node cooperation enforcement, the proposed solutions can be subdivided into two main categories: trade-based schemes and reputation-based schemes. In trade-based schemes, a node that provides some service to a peer node (e.g., packet forwarding) is rewarded by either another immediate service in exchange or some monetary token that he can later use to buy services from another node. In reputation-based schemes each node keeps a reputation metric for other nodes it deals with and provides services only to nodes that exhibit good reputation.

In all reputation-based mechanisms for cooperation enforcement, each node in the network performs two distinct functions: rating the behavior of neighboring nodes and using these ratings to adjust its own behavior towards them. Rating the conformance of neighboring nodes to a given network protocol is an operation that depends on the specific protocol and network architecture. For instance, in single-channel MANETs, rating the packet forwarding service provided by a node's neighbors is simply performed through monitoring of the common channel. However, in clustered MANETs, which use different channels in each cluster and bridge nodes to relay packets between clusters (such as Bluetooth scatter nets), a node cannot receive the transmissions of all of his neighbors. Hence, a different technique for rating the forwarding services provided by them is needed. Similarly, rating the conformance to a neighborhood discovery protocol or a Medium Access protocol is fundamentally different than rating packet forwarding.

On the other hand, a cooperation reinforcing reputation mechanism can be easily adapted to use such behavior ratings independently of the rated service. A crucial task for this mechanism is to distinguish between perceived and actual non-cooperative behavior. For example an MT might receive a bad cooperation rating because of link failure or mobility. Misbehaving MTs might also choose to misbehave in a probabilistic way in order to evade detection. If erroneously perceived misbehavior is permitted with a certain probability, then the detection of intentional misbehavior is reduced to an estimation problem.

Secure Service Discovery

The service discovery may be performed using a hierarchical multi-tier approach based on several tiers. A service manager (SM) discovers and manages the services in its corresponding tier and interacts with its upper-tier SM. All the available public and private services provided by foreign nodes, directly attached to the network, or provided by any other kind of infrastructure network will be discovered, subject to authentication and authorization.

In the service discovery architecture, the protocols used for communication are some common service discovery protocols, such as UPnP, Bluetooth SDP, and JXTA. At the highest level, the objective is to create an environment where message-level transactions and business processes can be conducted securely in an end-to-end fashion. There is therefore a need to ensure that messages are secured during transit, with or without the presence of intermediate nodes. There may also be a need to ensure the security of the data in storage. The requirements for providing end-to-end security for the service discovery are summarized as follows:

- **Secure service registration and deregistration:** Service registration and deregistration corresponds to service information management by the SMs. Only authorized service providers should be allowed to register and deregister a service from the repository. Meanwhile, it is important to maintain the integrity and confidentiality of the registered services in the service registration and deregistration process. Other types of attacks should be mitigated such as message replay and spoofing. Efficient message authentications through signatures or keyed hash-functions are suitable countermeasures for these attacks.
- **Secure authorization:** Authorized service discovery is needed to control the discoverable services by each entity. On the one hand, users may be authorized to perform a service discovery, but based on their set of credentials, they may only have a controlled visibility of available services. On the other hand, the discovered service must be genuine and trustworthy. Finally, the anonymity of the entity performing the service discovery

and confidentiality of the process should also be ensured.

- **Secure Service Delivery/Provisioning:** After a service has been found, it should be securely delivered by the mutual authentication between the recipient of the service and the service provider. Delivery confidentiality and service integrity must also be met so that the genuine and authentic service is only delivered to the intended recipient(s). As for secure service discovery, anonymity with reference to the location and identity can also be required.
- **Dependability:** Dependability can be defined as the property of a system, which always honors any legitimate requests by authorized entities. It is violated when an attacker succeeds in denying service access to legitimate users (e.g., by exhausting all the available resources through the DoS attack).
- **Service Access Control:** Future architectures should contain an AAA component that assigns each service a security profile describing the required security and trust level of the user in order to access the service (Sisalem & Kuthan, 2004)). Profiles determine the access rights for users and contain authorized users, credentials needed, certificates, subscription to groups, and so forth. Profile management can be done by the node, offering the particular service (de-centralized approach) and SM as the service advertiser when evaluating the decision to respond to queries (centralized approach). Using both centralized and de-centralized management methods, it will protect the various access networks (3G, WLAN/WMAN, PAN/PN) from unauthorized use and will keep the management procedure fast and reliable.

Context-Aware Security

One of the basic requirements for B3G is to support seamless mobility, such that the user does not perceive any delay or interruption of service in heterogeneous networks. To provide seamless mobility, handover between networks of either heterogeneous technologies or different administrative domains must be smooth and secure. Because each network may deploy its own security mechanisms that are incompatible with others, seamless handover imposes certain restrictions for maintaining the same security level and minimum delay.

Context transfer aims to minimize the impact of certain transport/routing/security-related services on the handover performance (Loughney, Nakhjiri, Perkins, & Koodli, 2004). When a mobile node (MN) moves to a new subnet, it needs to maintain services that have already been established at the previous subnet. Such services are known as 'context transfer candidate services', and examples of these services include QoS policy, AAA profile, IPsec state, header compression, session maintenance, and so forth. Re-establishing these services at the new RAN will require a considerable amount of time for the protocol exchanges, and as a result time-sensitive real-time traffic will suffer during this time. Alternatively, context transfer candidate services state information can be transferred, for example, from the previous RAN to the new RAN so that the services can be quickly re-established. A context transfer protocol will result in a quick re-establishment of context transfer candidate services at the new domain. It would also contribute to the seamless operation of multimedia application streams and could reduce susceptibility to errors. Furthermore, re-initiation to and from the mobile node will be avoided, hence wireless bandwidth efficiency will be conserved (Georgiades, Dagiuklas, & Tafazolli, 2006).

Context transfer requirements should consider the following:

1. **Context management and user control:** In many activities in the research community, context information is considered to be important to support usage, operation, and management of heterogeneous wireless network (3G, WLANs, emerging 4G) and service provided by these networks.
2. **Secure context transfer of security information in handovers between heterogeneous access technologies or network types:** When a handover occurs, timing constraints may forbid performing a full new access procedure, including authentication and key agreement. Instead, the security context may be transferred between points of attachment in the network which trust each other. The precise nature of the transferred security context must be specified, and the security for the discovery of points of attachment and of the transferred context need to be further studied and researched, especially during vertical handover.
3. **Secure context adaptation of security information in handovers between heterogeneous access networks:** It may not be sufficient to merely transfer the security context in a handover, but the security context may need to be adapted according to the new environment. For instance, the IP address in an IPsec Security Association may change, or different cryptographic mechanisms or schemes to protect communication traffic may be used.

MULTIMEDIA PROVISIONING

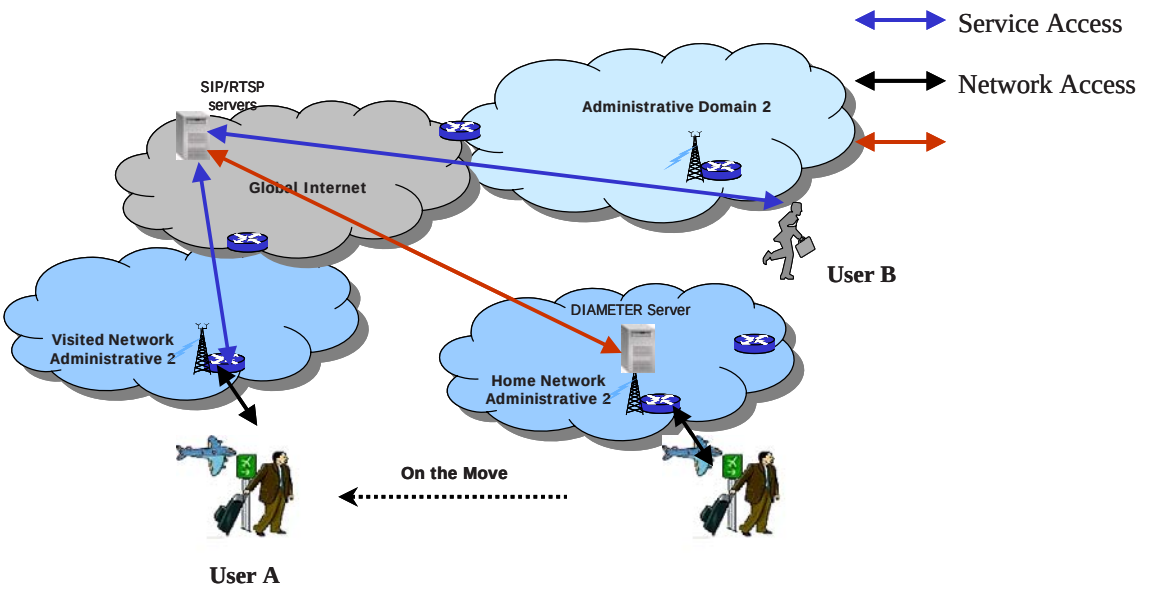
The implementation of demanding services, such as real-time applications and streaming multimedia, in mobile environments using wireless connections has attracted considerable attention over the last few years. Efficient mobility management is considered to be one of the major factors towards seamless provision of multimedia applications across heterogeneous networks (Dagiuklas et al., 2005).

In order to cope with the requirements imposed by the NGN architecture, the IP multimedia subsystem (IMS) has been specified by 3GPP as a comprehensive service framework for both basic calling and enhanced multimedia services (3GPP, 2004). The IMS is the key enabler in the mobile world for providing rich multimedia services to the end users. The IMS enables complex IP-based multimedia sessions to be created with guaranteed QoS for each media component, ensuring that multimedia sessions will be able to reserve the resources they need and are authorized to use in order to perform satisfactorily. The IMS does not standardize any applications, only the service capabilities required to build various services. As a result, real-time and non-real-time multimedia services can easily be integrated over a common IP-based transport. The functions supported by the IMS include quality of service control, interworking and roaming, service control, and multiple network access. Session initiation protocol (SIP) was chosen as the session control protocol for IMS, which is based on HTTP and uses all service frameworks developed for HTTP. In addition diameter was chosen to be the AAA protocol in the IMS.

Taking into account a mixed environment with both fixed and mobile users and the currently standardized protocols SIP and diameter, several extensions for a complete and integrated security framework with a well-defined identification mechanism and a fully defined intercommunication method with AAA architecture are needed (Camarillo & Garcia-Martin, 2004). Multimedia provisioning across heterogeneous networks should consider the following aspects:

- **Application level security:** SIP security mechanisms can be embodied within SIP body message including encryption (enables the possibility to ensure privacy) and AAA.

Figure 3. AAA and SIP interworking scenario



- **SDP security and media security extensions:** A number of SDP extensions have been motivated by SIP-based applications, and these need to be accommodated in SDP, which now supports the use of the SRTP/SRTCP protocol. The definition of the SRTP protocol is still in draft phase and under discussion. Features associated with key management attributes need to be included (not just for SIP) and so may need to be general mechanisms to signal security capabilities.
- **SIP identity integrity:** The identity information asserted by the sender of a request is the 'From' header containing an URI (like 'sip: ipolitis@ee.upatras.gr') and an optional display name (like "Ilias") that identifies the originator of the request.
- **SIP privacy:** The privacy problem is further complicated by proxy servers (also referred to in this document as "intermediaries" or "the network") that add headers of their own, such as the record-route and via headers.
- **End-to-End QoS:** Current approaches focus on QoS control in the access part, but the QoS control among service providers is still an open issue (Farkas et al., 2006).

CONCLUSION

In conclusion this article relates the functionalities and AAA infrastructure in order to support the dynamic establishment of trust relations between independent providers in a secure and distributed manner. The support of NGN networks involves research work on vast areas ranging from mobility, quality of service (QoS), roaming models, security, and integration with current networks. Towards the establishment of heterogeneous networks and services, solutions have been presented for supporting the provision of multimedia services over heterogeneous networks, benefiting from the availability of standardized solutions (IMS, Diameter, SIP, etc.) for supporting the operators' needs and solving issues of heterogeneity. Finally, implementing the envisaged conditions, the users' freedom to roam between different networks and use any locally available services in secure and satisfactory manner is increased.

KEY TERMS

Authentication Authorization Accounting (AAA): Provides the framework for the construction of a network architecture that protects the network operator and its customers from attacks and inappropriate resource management and loss of revenue.

Diameter: An AAA protocol for applications such as network access or IP mobility. It is a base protocol that can be extended in order to provide AAA services to new access technologies; it is intended to work in both local and roaming AAA situations**.**

IP Multimedia Subsystem (IMS): Provides a framework for the deployment of both basic calling and enhanced multimedia services over IP core.

Liberty Alliance: Broad-based industry standards consortium developing suites of specifications defining federated identity management and Web services communication protocols that are suitable for both intra-enterprise and inter-enterprise deployments.

Quality of Service (QoS): The probability of the telecommunication network meeting a given traffic contract, or in many cases used informally to refer to the probability of a packet succeeding in passing between two points in the network.

MANET: Mobile ad-hoc network.

Next Generation Networking (NGN): A broad term for a certain kind of emerging computer network architectures and technologies which generally describes networks that natively encompass data and voice (PSTN) communications, as well as (optionally) additional media such as video.

Remote Authentication Dial-In User Service (RADIUS): An AAA protocol for applications such as network access or IP mobility.

Session Initiation Protocol (SIP): A protocol developed by the IETF MMUSIC Working Group and proposed standard for initiating, modifying, and terminating an interactive user session that involves multimedia elements such as video, voice, instant messaging, online games, and virtual reality. It is one of the leading signaling protocols for voice over IP.

Service Manager (SM): A server that discovers and manages services in its corresponding tier and interfaces with its upper-tier SM.

Triple Play: A term for the provisioning of the three services—high-speed Internet, television (video-on-demand or regular broadcasts), and telephone service—over a single broadband wired or wireless connection.

Chapter 4.4
Adaptive Narrative Virtual Environments

Karl Steiner
University of North Texas, USA

ABSTRACT

Narratives are an important method of human-to-human communication. Combining the power of narrative with the flexibility of virtual environments (VEs) can create new and innovative opportunities in education, in entertainment, and in visualization. In this chapter, we explore the topic of narrative VEs. We describe the characteristics and benefits of narrative VEs, review related work in VEs and in computer-generated narrative, and outline components of an architecture for managing narrative VEs. We present the current status of our work developing such an architecture and conclude by discussing what the future of narrative VEs may hold.

INTRODUCTION

Storytelling is a significant method of human-to-human communication. We tell stories to share ideas, to convey emotions, and to educate. As new communication technologies have become available we have employed them in our storytelling, allowing us to reach wider audiences or to tell stories in new ways. Narratives were among the initial and most popular content types as books, radio, movies, and television were introduced to the public. VEs may provide the next technological advancement for presenting narratives. Consider the following examples.

Illustration 1

An inexperienced army specialist enters an immersive simulator in order to practice skills such as identifying and overcoming threats in an urban environment. The specialist encounters a hostile unit on Main Street, but chooses to retreat to a safe location. No longer sure of her ability to handle the hostile unit, the officer continues to explore the environment, but avoids Main Street. Aware that the specialist is no longer able to interact with the hostile unit on Main Street, the environment attempts to surprise the officer with a new hostile unit near her current location. This time she is better prepared. Rather than retreat, she engages and subdues the hostile unit.

Illustration 2

A child, nervous about an upcoming surgery, is given an opportunity to explore a virtual hospital. The child follows a patient about to undergo similar surgery, sees all the preparations that take place, and becomes familiar with the various people who are involved in the procedure. While he does not see the actual surgery take place, the environment makes sure the child notices that there are other children waiting for surgery and that they are all experiencing many of the same emotions that he is. He is reassured after his exploration — not just with his knowledge of the procedure, but that his fears and concerns are normal.

Illustration 3

A young adult begins interacting with a new mystery game set in a virtual environment. In the initial interactions, the player continually chooses to explore the environment and look for clues, rather than chase and subdue suspects. Noting the players interests, the game adjusts the plotline to emphasize puzzles rather than conflicts.

These examples illustrate three powerful, yet underutilized, potentials of VEs. The first attribute is that events occur not randomly, but according to a plan based on scenario or narrative goals. The second attribute is that the system may recognize and respond to user goals and interests in addition to the given scenario goals. And the third attribute is that the system chooses when, where, and how to present events in order to best meet the user and scenario goals.

In this chapter, we will explore the topic of narrative VEs. We begin by describing the characteristics and benefits of narrative VE. We review related work that has influenced the current state of both VE and computer-generated narrative and outline components of an architecture for managing narrative VE. We describe the current status of our work developing such an architecture and conclude by discussing what the future of narrative VE may hold.

BACKGROUND

Narrative VE

Narrative VEs are an emerging multimedia technology, integrating storytelling techniques into VEs. VEs and virtual reality have been defined in different ways. For this chapter, we will define a VE as a computer-generated 3D space with which a user can interact. The concept of narrative also has different meanings in different contexts. In our work, we consider a narrative to be a sequence of events with a conflict and resolution structure (a story). So, for us, a narrative VE is an immersive, computer-generated 3D world in which sequences of events are presented in order to tell a story.

Not all VEs are narrative, nor are VEs the only way of presenting computer-based narratives. Most VEs do not have an explicitly narrative structure. While most VEs include events of some sort, they do not provide the plot-driven selection and ordering of events that separates stories from simulation. For example, a driving simulator might model the roadways of a city, complete with cars, pedestrians, and traffic signals. Events in this simulation-oriented VE might include a traffic light changing from green to red, a pedestrian successfully crossing an intersection, or a collision between two cars.

In a simulation, the rules that govern when and how events occur are based primarily on attributes of the world and the object within it. In our driving VE, the stoplight may cycle from green to yellow to red every 30 seconds. Pedestrians cross roads successfully when there is no traffic. A collision may occur whenever the paths of two objects intersect at the same point in space and time. While simulation rules are adequate to describe object-object interactions and can even be used to model very complex environments (such as flying a 747 or driving through city traffic), they do not typically address broader goals or plans of the users or authors of the environment. The rules and random probabilities of a simulator do

not take into account how an event will impact the environment or the user.

In a narrative VE, however, the occurrences of at least some key events are based on storytelling goals. For example, in a narrative VE designed to illustrate the dangers of jaywalking, the stoplight may turn green as soon as the user's car approaches the intersection. The pedestrian may wait to start crossing the intersection until the user's car enters the intersection. While these events may be similar to those in a simulator (traffic signal changes color, pedestrian crosses the street), the timing, placement, and representation of these events is done in such a manner as to communicate a particular story. This is what differentiates a simulation from a narrative.

Benefits of Narrative VE

Combining the power of narrative with the power of VEs creates a number of potential benefits. New ways of experiencing narratives as well as new types of VE applications may become possible. Existing VE applications may become more effective to run or more efficient to construct.

Narrative VE can extend our traditional ideas of narrative. Unlike traditional narrative media, narrative VE can be dynamic, nonlinear, and interactive. The events in a narrative VE would be ultimately malleable, adapting themselves according to a user's needs and desires, the author's goals, or context and user interaction. A narrative VE might present a story in different ways based on a user profile that indicates whether the user prefers adventure or romance. A user could choose to view the same event from the viewpoint of different characters or reverse the flow of time and change decisions made by a character. A narrative VE might adapt events in order to enhance the entertainment, the education, or the communication provided by the environment. And a narrative VE might adapt events in order to maintain logical continuity and to preserve the suspension of disbelief (Murray, 1998).

These narrative capabilities could also open up new application areas for VE. Training scenarios that engage the participant, provide incrementally greater challenges, and encourage new forms of collaboration could become possible (Steiner, 2002). Interactive, immersive dramas could be created where the user becomes a participant in the story (Laurel, 1991). Presentations of temporal or spatial data could be self-organizing, arranging and rearranging the data based on different perspectives or emphases (Gershon, 2002).

While it is possible to add narrative elements to an otherwise simulation-oriented VE, the process can be difficult for designers, and the results less than satisfying for users. The most common application area for simulation-oriented VEs with narrative elements is computer games. A review of the current state of the art in 3D narrative games is instructive in considering the challenges VE designers face.

Many computer games now include narrative elements, though the quality and integration of the narratives vary widely. One of the most common narrative elements is a full screen video (FSV) cut-scene that advances the storyline. These typically take place after a player has completed a level or accomplished some other goal. Other devices include conversations with non-player characters (NPCs) that are communicated as actual speech, as text, or as a FSV. These conversations are typically scripted in advance, with the only interactivity coming from allowing the user to choose from prepared responses.

Even with the best-produced narrative games, the narratives are generally tightly scripted and linear, providing little or no opportunity for influencing the plot of the story. Since the environment remains unaware of narrative goals, the designer must take measures to force users into viewing narrative events. This usually means either eliminating interactivity and forcing users to watch FSVs; or keeping interactivity, but eliminating choices so that the user must ultimately proceed down a particular path or choose a particular

interaction. These solutions are unsatisfying for many users and time consuming for designers to construct.

A fundamental issue behind the limited interactivity is the tension between the user's desire to freely explore and interact with the environment and the designer's goals of having users experience particular educational, entertaining, or emotional events. Advances in visualization technology have exacerbated the issue. VEs are now capable of modeling more objects, behaviors, and relationships than a user can readily view or comprehend. Techniques for automatically selecting which events or information to present and how to present it are not available, so VE designers must explicitly specify the time, location, and conditions under which events may occur. As a result, most VEs support mainly linear narratives or scenarios (if they support them at all).

Related Work

While there has been substantial research on the application of certain intelligent techniques to VEs, there has been little attention to adaptive interfaces for narrative VE. Still, in realizing an architecture for adaptive narrative VE, many lessons can be drawn from work in related areas. These include adaptive interfaces, intelligent agents in VE, automated cinematography in VE, narrative multimedia, and narrative presentation in VE.

Adaptive interfaces are those that change based on the task, work context, or the needs of the user. Often, the successful application of an adaptive interface requires simultaneous development of a user modeling component. A user modeling system allows the computer to maintain knowledge about the user and to make inferences regarding their activities or goals.

Adaptive interfaces allow computer applications to be more flexible, to deal with task and navigation complexity, and to deal with divers user characteristics and goals. Adaptive interfaces can be applied to almost any human/computer interaction. For example, the immense popularity of the WWW has lead to a corresponding amount of research on adaptive hypermedia. Similarly, adaptive techniques based on user models can also be employed in VEs.

Automated cinematography is a form of adaptivity particularly for VEs. Camera controllers or automated cinematographers are designed to free users and designers from explicitly specifying views. Simple camera controllers may follow a character at a fixed distance and angle, repositioning in order to avoid occluding objects or to compensate for user actions such as running. More complex controllers seek to model cinematography convention (He, 1996), to dynamically generate optimal camera angles to support explicitly stated user viewing or task goals (Bares, 1999), or to link camera control to a model of the ongoing narrative (Amerson, 2001).

Over the years, researchers have created various systems for dynamically generating textual narratives. One of the earliest systems, Talespin, created fable-like stories (Meehan, 1980). These narratives exhibited a conflict-resolution structure driven by characters seeking to achieve their goals; but the text was frequently repetitive, and the stories were not particularly engaging. Universe (Lebowitz, 1984) created a dynamic textual narrative based on a simulation of characters in a soap opera. While such a setting provides rich dramatic content, the narrative was again dictated by characters pursuing goals, rather than being dictated by a plot. In more recent work (Calloway, 2001) researchers have created the Author Architecture and the Storybook application, a narrative generation system capable of creating real-time fairy tale text almost on a par with human generated text.

A natural extension of the character driven textual narratives are character-driven VEs. Several VE systems have been built which allow users to interact with lifelike, believable, or emotional agents (Hayes-Roth, 1996). As with the

character-driven textual systems, the results of interacting with these agents may be interesting or believable; but they may not exhibit an overall narrative coherence.

There has also been work on VE environments that seek to provide such coherence. In the OZ Architecture for Dramatic Guidance (Weyhrauch, 1997) a director gives instructions to actors in a VE, seeking to maximize the dramatic potential of a situation. Mimesis (Young, 2001) includes a director that works to detect and prevent potential plot conflicts due to user activities. The Dogmatics project (Galyean, 1995) attempts to direct user attention by manipulating the environment.

AN ARCHITECTURE FOR NARRATIVE VE INTELLIGENT INTERFACE

Building on this prior work, we are developing an architecture for adaptive narrative in VEs. This architecture combines components common to adaptive systems and VE systems and adds data and control structures capable of representing and reasoning about narratives. The architecture includes the following components: Adaptation Manager, Narrative Manager, User Modeler, and a 3D Engine. While other VE systems devoted to narrative presentation have addressed elements of VE architecture, we believe that our approach to adapting events represents a unique contribution to the field. Our narrative VE architecture is illustrated in Figure 1.

3D Engine and World State

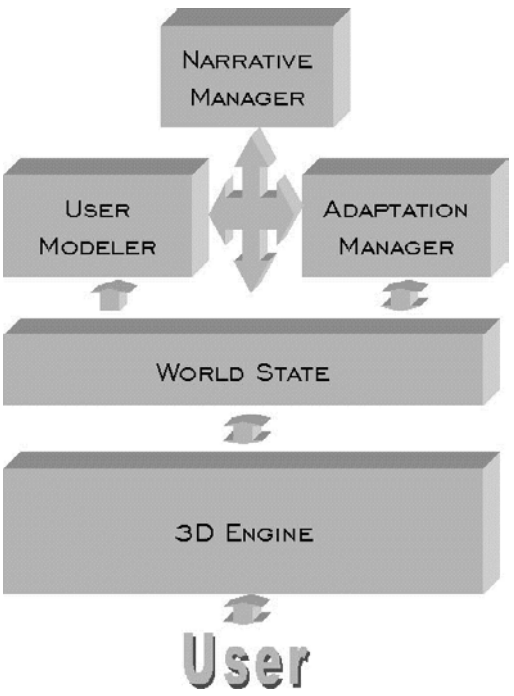
Graphic VEs of the type we have been describing (as opposed to textual VEs such as MUDs and MOOs) rely on a 3D Engine to render the real-time images that make up the visual presentation of the environment. While there are many relevant research topics related to presentation of 3D images, our research focuses primarily upon technologies related to interaction, adaptivity, and narrative. Accordingly, rather than develop our own 3D engine, we have taken advantage of the many powerful VE environments that are now available to researchers and commercial developers. Like a growing number of academic researchers, we have found that the ease of development and flexibility of the current suite of game engines meets our development needs (Lewis, 2002). In particular, we are using the A5 3D game engine from Conitec.

The world state contains information about the object within the world, such as its location and its current status. This information may be maintained within the 3D engine or may be managed by an external data store.

User Modeler

User modeling describes the ability of a system to make observations about a user and to use

Figure 1. Adaptive narrative VE architecture



these observations to adapt the experience to better meet the user's wants or needs. For a narrative VE system, the user model could receive information such as a user profile, a history of user activities within the VE, and information about the activities of others with the VE. Using this information, the User Modeler could provide information regarding the user beliefs about the current story or which aspects of the story appear interesting to the user.

In order to develop reliable inferences, the User Modeler would require a variety of input. This input could include information regarding user information and attributes (e.g., age, occupation, computer experience, hobbies and interests, etc.). The user model would also receive a record of activities performed by the user within the environment. This activity log would be more than just a list of specific interactions (e.g., movement to coordinates X, Y, Z, interaction with object Q, etc.), but would also provide contextual information used to establish the significance of interactions (e.g., moved farther away the threatening dog, interacted with the door to unlock the secret room, etc.). Using this information, the system could generate various "beliefs" about the user, such as the user's goals (the user seeks recreation and intellectual stimulation), the users interests within the narrative VE (the user is seeking treasure and wealth), what the user believes about the narrative or the VE (the user believes there is a treasure in the hidden room or the user believes that the dog is hostile and will attack), and whether the user falls into a recognized "type" (the user is an "explorer" rather than a "fighter").

Narrative Manager

In order to present a story, a VE requires some control mechanism for scheduling and presenting the events that make up the narrative. While simulation-oriented VE have rules for triggering or scheduling events, they do not take into account the narrative purpose of the events, instead focusing on some other guiding structure such as game physics. In the simplest narrative VEs (such as many recent computer games), narrative events are "canned" FSV pieces that occur when certain conditions are met, such as completion of a level, or the solution of a puzzle. In a more robust narrative VE, there would be more variety in the type of events, in the scheduling of events, and in the presentation of events. For example, in addition to or instead of FSV, events might be more contextually inserted into the environment itself. Instead of a pre-recorded FSV showing one character talking to another at a particular location, a real-time animation of the characters can be dynamically created showing their conversation at any location. Instead of narrative events occurring only between levels, narrative events might occur anytime or anywhere within the environment, with the timing, placement, and form of the event being dictated by the storytelling goals of the system (see Adaptation Manager). The basic outline of the narrative (or the plot of the story) could be predefined by a human author or could be generated dynamically by the computer.

In our current implementation, the outline of the story is expressed through narrative events (see Figure 2). Other interactions may take place in the system, but the narrative events are those that have significance to the story, have corresponding triggers, and have their presentation controlled by the Adaptation Manager.

Adaptation Manager

Given an event and contextual information, the system should be capable of modifying the event to maintain plot and logical continuity and to help the user and author achieve their narrative goals. For the author, these goals may include communicating an idea, teaching a lesson, or conveying an emotion. For the user, goals might include entertainment, education, relaxation, or excitement. As input, the Adaptation Manager would use information from the Narrative Manager (narrative events), the User Modeler (user goals or beliefs), and the world state (object loca-

Figure 2. Event data structures

NARRATIVE EVENT		
SLOT	**DESCRIPTION**	
Name	Name of Event	
Location	Location where event should occur	
Time	When event should occur	
Participants	Actors who are involved in event	
Actions	Set of actions that make up the event	
Presentation	The preferred form of communicating the actions, e.g. direct observation, indirect observation, hearing, intermediated, etc.	
Side Effect	Facts or flags that should be set as a result of this event	
NARRATIVE EVENT TRIGGER		
CRITERIA	**DESCRIPTION**	**EXAMPLES**
Time	Events may need to occur at a specific or relative time or in a specific sequence.	`Session-ends` should occur 20 minutes after `session begins;` `Car-breaks-on-ice` should occur immediately after `car-accelerates-past-user`
Location	Events may need to occur when actors (human or computer) arrive at or leave certain locations	`Stoplight-turns-red` should occur when user arrives at corner of main and center
Other	Events may need to occur when other conditions (indicated by flags, often set as a result of a side-effect associated with an event)	`Car-stops` should occur when `car-out-of-gas` is true
ACTION		
SLOT	**DESCRIPTION**	
Actor	Actor or object who is to perform the action	
Action	Specific primitive action that the actor performs (e.g. animation, movement, function, etc.)	
Object (optional)	Actors or object to or on whom the actor performs the action	
Other Parameters (optional)	Any other parameters necessary to specify the Action	

tions). Given a particular event suggested by the Narrative Manager, the Adaptation Manager will select time, place, and representation based on event constraints, narrative goals, and the state of the world.

CURRENT STATUS

Development is proceeding in phases. We have completed a pilot adaptive narrative VE that includes a limited set of events, a scripted narrative, and an active Presentation Manager. We are in the process of conducting user studies comparing user comprehension and satisfaction both with and without presentation management. This feedback will guide us in extending the supported set of events and the types of adaptation supported by the Adaptation Manager. We have also begun work on the User Modeler and plan to turn our attention next to dynamic narrative generation. The following sample interaction provides an

example of some of the current types of adaptation supported by our system.

Sample Interaction

In order to test the Adaptation Manager, our event representation scheme, and our overall framework, we have created a sample narrative. The narrative was constructed to include enough events and complexity to exercise a variety of adaptation techniques. The narrative includes multiple characters, a plot consisting of multiple events (including several events that may occur simultaneously), and the events take place at multiple locations in a 3D VE.

Event: A hungry rabbit eats the last of his carrots and goes looking for something else to eat.
Actions: Animation of rabbit eating carrots. Sounds of rabbit eating carrots.
Adaptations: Amplify sound of rabbit eating carrots (to draw attention to rabbit and convey idea that someone is eating something). (Figure 3)
Event: The rabbit notices a snowman's carrot nose and steals it.
Actions: Animation and sounds of rabbit stealing carrot nose.
Adaptations: Delay actions until user is present at the characters' location (so that user may view and hear this key event). (Figure 4)

Event: The snowman follows the rabbit to the lake, but the rabbit has already eaten the carrot. The only item he can find is a dead fish, so he uses that as a temporary replacement.
Actions: Sounds of snowman and rabbit discussing options. Animation of snowman picking up fish and using it as nose.
Adaptations: If the user was not present to see the event, the rabbit talks to himself and recounts the event within the hearing distance of the user. (Figure 5)

FUTURE TRENDS

If the public's past and current appetite for narrative and interactive technology are any guides, then continued development and use of new narrative technologies such as adaptive VEs is likely to be rapid. This development could usher in a generation of more sophisticated and personalized computer training, communication, and entertain-

Figure 3.

Figure 4.

ment applications, providing more opportunities for people to interact with multimedia technologies. While some may have concerns that such systems could isolate users by providing them with replacements for human interaction, we feel that some of the greatest opportunities for such technologies would be in creating novel and powerful new ways for people to interact with each other. Collaborative narrative VEs could bring users together to explore stories and situations, even if the users were in physically remote locations. In addition to experiencing narratives in new ways, advances in input and output technologies may also allow us to experience narrative in new places. Using augmented or mixed reality technology, a VE could be overlaid on top of the real world, allowing virtual characters and objects to appear side-by-side with real objects. Such technologies would allow us to experience stories anywhere and to incorporate any location into part of an ongoing personal narrative.

CONCLUSION

The application of AI techniques in narrative generation and adaptation to multimedia technologies such as VEs can create new types of experiences for users and authors. We have explored an architecture that supports not only the presentation of a single narrative, but an adaptive capability that would allow narratives to be customized for different users, different goals, and different situations. The development of this pilot application has demonstrated the feasibility of this architecture, and we plan to continue to extend and enhance the capabilities of our system.

Chapter 4.5
Semantically Driven Multimedia Querying and Presentation

Isabel F. Cruz
University of Illinois, Chicago, USA

Olga Sayenko
University of Illinois, Chicago, USA

ABSTRACT

Semantics can play an important role in multimedia content retrieval and presentation. Although a complete semantic description of a multimedia object may be difficult to generate, we show that even a limited description can be explored so as to provide significant added functionality in the retrieval and presentation of multimedia. In this chapter we describe the Delaunay^{View} that supports distributed and heterogeneous multimedia sources and proposes a flexible semantically driven approach to the selection and display of multimedia content.

INTRODUCTION

The goal of a semantically driven multimedia retrieval and presentation system is to explore the semantics of the data so as to provide the user with a rich selection criteria and an expressive set of relationships among the data, which will enable the meaningful extraction and display of the multimedia objects. The major obstacle in developing such a system is the lack of an accurate and simple way of extracting the semantic content that is encapsulated in multimedia objects and in their inter-relationships. However, metadata that reflect multimedia semantics may be associated with multimedia content. While metadata may not be equivalent to an ideal semantic description, we explore and demonstrate its possibilities in our proposed framework. Delaunay^{View} is envisioned as a system that allows users to retrieve multimedia content and interactively specify its presentation using a semantically driven approach.

Delaunay^{View} incorporates several ideas from the earlier systems Delaunay (Cruz & Leveille, 2000) and Delaunay^{MM} (Cruz & James, 1999). In the Delaunay^{View} framework, multimedia content is stored in autonomous and heterogeneous sources

annotated with metadata descriptions in resource description framework (RDF) format (Klyne & Carroll, 2004). One such source could be a database storing scientific aerial photographs and descriptions of where and when the photographs were taken. The framework provides tools for specifying connections between multimedia items that allow users to create an integrated virtual multimedia source that can be queried using RQL (Karvounarakis et al., 2002) and keyword searches. For example, one could specify how a location attribute from the aerial photo database maps to another location attribute of an infrared satellite image database so that a user can retrieve images of the same location from both databases.

In Delaunay^{View}, customizable multimedia presentation is enabled by a set of graphical interfaces that allow users to bind the retrieved content to presentation templates (such as *slide sorters* or *bipartite graphs*), to specify content layout on the screen, and to describe how the dynamic visual interaction among multimedia objects can reflect the semantic relationships among them. For example, a user can specify that aerial photos will be displayed in a slide sorter on the left of the workspace, satellite images in another slide sorter on the bottom of the workspace, and that when a user selects a satellite image, the aerial photos will be reordered so that the photos related to the selected image appear first in the sorter.

In this paper we describe our approach to multimedia querying and presentation and focus on how multimedia semantics can be used in these activities. In "Background" we discuss work in multimedia presentation, retrieval, and description; we also introduce concepts relating to metadata modeling and storage. In "A Pragmatic Approach to Multimedia Presentation", we present a case study that illustrates the use of our system and describe the system architecture. In "Future Work" we describe future research directions and summarize our findings in "Conclusions."

BACKGROUND

A multimedia presentation system relies on a number of technologies for describing, retrieving and presenting multimedia content. XML (Bray et al., 2000) is a widely accepted standard for interoperable information exchange. MPEG-7 (Martinez, 2003; Chang et al., 2001) makes use of XML to create rich and flexible descriptions of multimedia content. Delaunay^{View} relies on multimedia content descriptions for the retrieval and presentation of content, but it uses RDF (Klyne & Carroll, 2004) rather than XML. We chose RDF over XML because of its richer modeling capabilities, whereas in other components of the Delaunay^{View} system we have used XML (Cruz & Huang, 2004).

XML specifies a way to create structured documents that can be easily exchanged over the Web. An XML document contains *elements* that encapsulate data. *Attributes* may be used to describe certain properties of the elements. Elements participate in hierarchical relationships that determine the document structure. XML Schema (Fallside, 2001) provides tools for defining elements, attributes, and document structure. One can define typed elements that act as building blocks for a particular schema. XML Schema also supports inheritance, namespaces, and uniqueness.

MPEG-7 (Martínez, 2003) defines a set of tools for creating rich descriptions of multimedia content. These tools include *Descriptors*, *Description Schemes (DS)* (Salembier & Smith, 2001) and the *Description Definition Language (DDL)* (Hunter, 2001). MPEG-7 descriptions can be expressed in XML or in binary format. Descriptors represent low-level features such as texture and color that can be extracted automatically. Description Schemes are composed of multiple Descriptors and Description Schemes to create more complex descriptions of the content. For example, the MediaLocator DS describes the location of a multimedia item. The MediaLocator

is composed of the MediaURL descriptor and an optional MediaTime DS: the former contains the URL that points to the multimedia item, while the latter is meaningful in the case where the MediaLocator describes an audio or a video segment. Figure 1 shows an example of a MediaLocator DS and its descriptors RelTime and Duration that, respectively, describe the start time of a segment relative to the beginning of the entire piece and the segment duration.

The Resource Description Framework (RDF) offers an alternative approach to describing multimedia content. An RDF description consists of statements about *resources* and their *properties*. An RDF resource is any entity identifiable by a URI. An RDF statement is a triple consisting of subject, predicate, and object. The subject is the resource about which the statement is being made. The predicate is the property being described. The object is the value of this property. RDF Schema (RDFS) (Brickley & Guha, 2001) provides mechanisms for defining resource classes and their properties. If an RDF document conforms to an RDF schema (expressed in RDFS), resources in the document belong to classes defined in the schema. A class definition includes the class name and a list of class properties. A property definition includes domain — the subject of the corresponding RDF triple — and range — the object. The RDF Query Language (RQL) (Karvounarakis et al., 2002) is a query language for RDF and RDFS documents. It supports a select-from-where structure, basic queries and iterators that combine the basic queries into nested and aggregate queries, and generalized path expressions.

MPEG-7 Description Schemes and Delaunay^{View} differ in their approach to multimedia semantics. In MPEG-7, semantics are represented as a distinct description scheme that is narrowly aimed at narrative media. The Semantic DS includes description schemes for places, objects, events, and "agents" — people, groups, or other active entities — that operate within a narrative world associated with a multimedia item. In Delaunay^{View} any description of multimedia content can be considered a semantic description for the purposes of multimedia retrieval. Delaunay^{View} recognizes that, depending on the application, almost any description may be semantically valuable. For example, an aerial photo of the arctic ice sheet depicts some areas of intact ice sheet and others of open water. Traditional image processing techniques can be applied to the photo to extract light and dark regions that represent ice and open water respectively. In the climate research domain, the size, shape, and locations of these regions constitute the semantic description of the image. In MPEG-7 however, this information will be described with the StillRegion DS, which does not carry semantic significance.

Beyond their diverse perspectives on the nature of the semantics that they incorporate, MPEG-7 and Delaunay^{View} use different approaches to representing semantic descriptions: MPEG-7 uses XML, while Delaunay^{View} uses RDF. An XML document is structured according to the tree paradigm: each element is a node and its children are the nodes that represent its subelements. An RDF document is structured according to the directed graph paradigm: each resource is a node and each

Figure 1. MediaLocator description scheme

```
<MediaLocator>
    <MediaURL>http://www.cs.uic.edu/~advis/ex.mpg</MediaURL>
    <MediaTime>
        <RelTime>PT12S</RelTime>
        <Duration>PT34S</Duration>
    </MediaTime>
</MediaLocator>
```

property is a labeled directed edge from the subject to the object of the RDF statement. Unlike XML, where schema and documents are separate trees, an RDF document and its schema can be thought of as a single connected graph. This property of RDF enables straightforward implementation of more powerful keyword searches as a means of selecting multimedia for presentation. Thus using RDF as an underlying description format gives users more flexibility in selecting content for presentation.

Another distinctive feature between MPEG-7 and Delaunay^{View} is the focus of the latter on multimedia presentation. A reference model for intelligent multimedia presentation systems encompasses an architecture consisting of control, content, design, realization, and presentation display layers (Bordegoni et al., 1997). The user interacts with the control layer to direct the process of generating the presentation. The content layer includes the content selection component that retrieves the content, the media allocation component that determines in what form content will be presented, and ordering components. The design layer produces the presentation layout and further defines how individual multimedia objects will be displayed. The realization layer produces the presentation from the layout information provided by the design layer. The presentation display layer displays the presentation. Individual layers interact with a knowledge server that maintains information about customization.

LayLab demonstrates an approach to multimedia presentation that makes use of constraint solving (Graf, 1995). This approach is based on primitive graphical constraints such as "under" or "beside" that can be aggregated into complex visual techniques (e.g., alignment, ordering, grouping, and balance). Constraint hierarchies can be defined to specify design alternatives and to resolve overconstrained states. Geometrical placement heuristics are constructs that combine constraints with control knowledge.

Additional work in multimedia presentation and information visualization can be found in Baral et al. (1998), Bes et al. (2001), Cruz and Lucas (1997), Pattison and Phillips (2001), Ram et al. (1999), Roth et al. (1996), Shih and Davis (1997), and Weitzman and Wittenburg (1994).

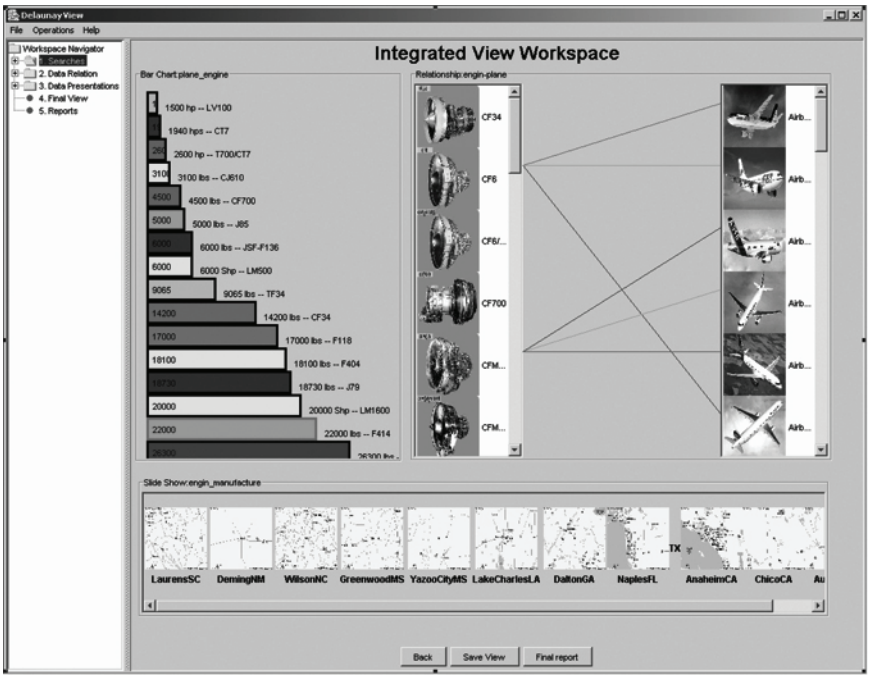
A PRAGMATIC APPROACH TO MULTIMEDIA PRESENTATION

In our approach to the design of a multimedia presentation system, we address the following challenges. Multimedia content is resident in distributed, heterogeneous, and autonomous sources. However, it is often necessary to access content from multiple sources. The data models and the design of the sources vary widely and are decided upon autonomously by the various entities that maintain them. Our approach accommodates this diversity by using RDFS to describe the multimedia sources in a simple and flexible way. The schemata are integrated into a single *global* schema that enables users to access the distributed and autonomous multimedia sources as if they were a single source. Another challenge is that the large volume of multimedia objects presented to the user makes it difficult to perceive and understand the relationships among them. Our system gives users the ability to construct customized layouts, thus making the semantic relationships among multimedia objects more obvious.

Case Study

This case study illustrates how multimedia can be retrieved and presented in an integrated view workspace using as example of a bill of materials for the aircraft industry. A bill of materials is a list of parts or components required to build a product. In Figure 2, the manufacturing of commercial airplanes is being planned using a coordinated visualization composed of three views:

Figure 2. A coordinated integrated visualization



a *bipartite graph*, a *bar chart*, and a *slide sorter*. The *bipartite graph* illustrates the part-subpart relationship between commercial aircrafts and their engines, the *bar chart* displays the number of engines currently available in the inventory of a plant or plants, and the *slide sorter* shows the maps associated with the manufacturing plants.

First, the user constructs a keyword query using the Search Workspace to obtain a data set. This process may be repeated several times to get data sets related to airplanes, engines, and plants. The user can preview the data retrieved from the query, further refine the query, and name the data set for future use.

Then, relationships are selected (if previously defined) or defined among the data sets, using metadata, a query, or user annotations. In the first two cases, the user selects a relationship that was provided by the integration layer. An example of such a relationship would be the connection that is established between the attribute engine of the airplane data set (containing one engine used in that airplane) and the engine data set. Other more complex relationships can be established using an RQL query.

Yet another type of relationship can be a connection that is established by the user. This interface is shown in Figure 3. In this figure and those that follow, the left panel contains the overall navigation mechanism associated with the interface, allowing for any other step of the querying or visualization process to be undertaken. Note that we chose the bipartite component to provide visual feedback when defining binary relationships. This is the same component that is used for the display of *bipartite graphs*.

The next step involves creating the views, which are built using templates. A data set can be applied to different templates to form different views. The interface of Figure 4 illustrates a *slide sorter* of the maps where the manufacturers of aircraft engines are located. In this process, data attributes of the data set are bound to visual attributes of the visual template. For example, the

Figure 3. Relation workspace

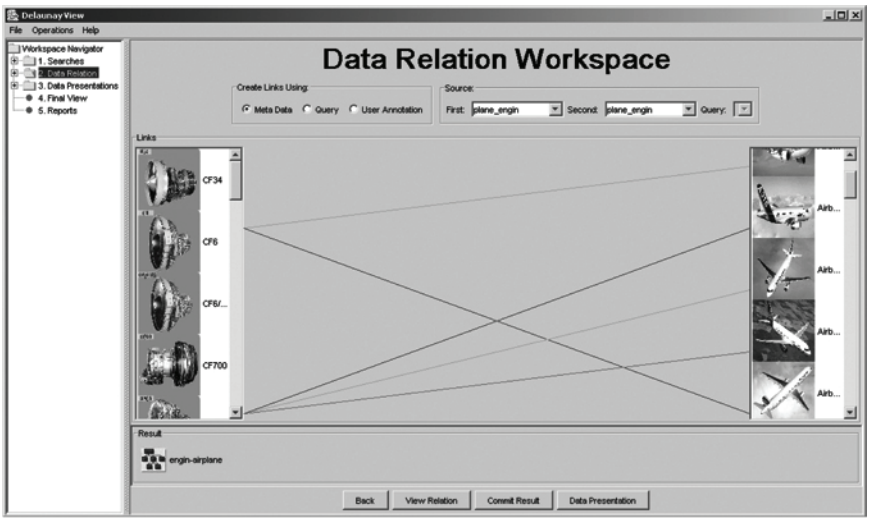


Figure 4. Construction of a view

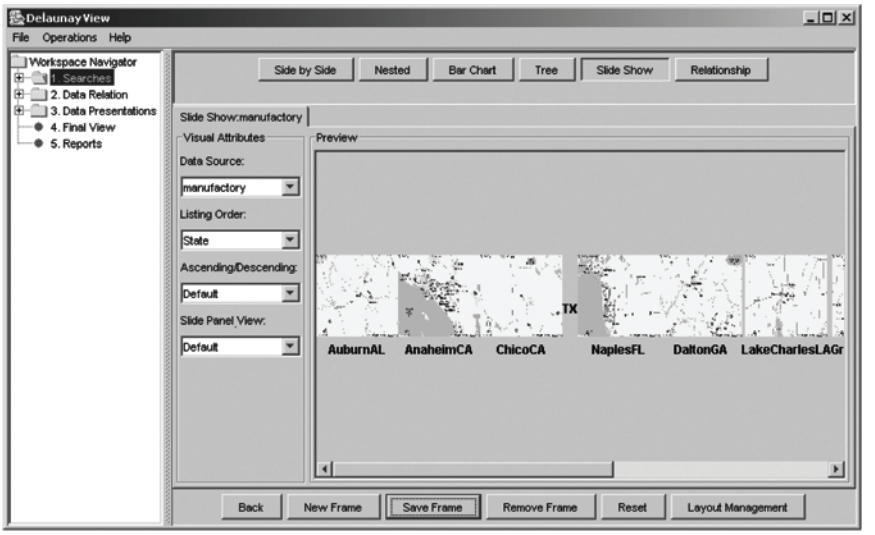
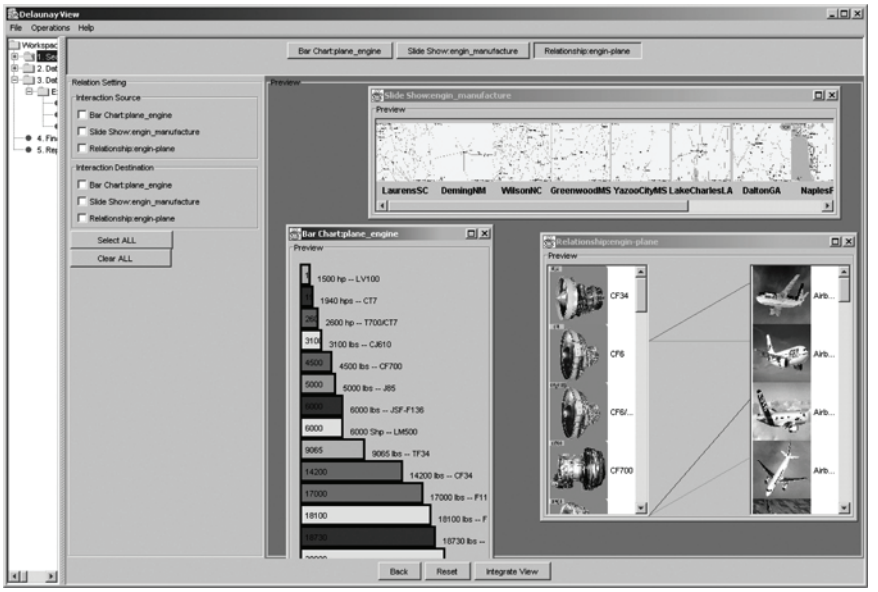


passenger capacity of a plane can be applied to the height of a *bar chart*. The users also can further change the view to conform to their preferences, for example, by changing the orientation of a *bar chart* from vertical to horizontal. The sorter allows the thumbnails to be sorted by the values of any of the attributes of the objects that are depicted by the thumbnails. Individual views can be laid out anywhere on the panel as shown in Figure 5. The user selects the kind of dynamic interaction between every pair of views by using a simple customization panel.

In the integrated view, the coordination between individual views has been established. By selecting a manufacturing plant in the *slide sorter*, the bar displays the inventory situation of the selected plant; for example, the availability of each type of airplane engine. By selecting more

Figure 5. View layout



plants in the sorter, the *bar chart* can display the aggregate number of available engines over several plants for each type of airplane engine.

There are two ways of displaying relationships: they can be either represented within the same visualization (as in the *bipartite graph* of Figure 2) or as a dynamic relationship between two different views, as in the interaction between the bar chart and sorter views. Other interactions are possible in our case study. For example, the *bipartite graph* can also react to the user selections on the sorter. As more selections of plants are performed on the sorter, different types of engines produced by the selected manufacturer(s) appear highlighted. Moreover, the *bipartite graph* view can be refreshed to display only the relationship between the corresponding selected items in the two data sets.

System Architecture

The Delaunay^{View} system is composed of the *presentation*, *integration*, and *data* layers. The data layer consists of a number of autonomous and heterogeneous multimedia data sources that contain images and metadata. The integration layer connects the individual sources into a single *integrated virtual source* that makes multimedia from the distributed sources available to the presentation layer. The presentation layer includes user interface components that allow for users to query the multimedia sources and to specify how the images returned by the queries should be displayed and what should be the interaction among those images.

Data Layer

The data layer is comprised of a number of autonomous *multimedia sources* that contain images annotated with metadata. An image has a number of attributes associated with it. First there are the low-level features that can be extracted automatically. In addition, there are the application-dependent attributes that may include timestamps, provenance, text annotations, and any number of other relevant characteristics. All of these attributes determine the semantics of the image in the application context. Image attributes are described by an RDF schema. When an image is

14      </aerial:image>
15  </rdf:RDF>
```

added to a multimedia source, it is given a unique identifier and stored in a binary string format. A document fragment containing image metadata is created and stored in the database.

Example 1: Let us consider a multimedia source that contains aerial photos of the Arctic ice sheet used in climate research. The relevant metadata attributes include date and time a photo was taken and the latitude and longitude of the location where it was taken. A photo taken on "08/22/2003 14:07:23" at 81°48'N, 1°40'E is represented in the following way: the image file is stored in table arctic (Figure 6) with identifier "QZ297492". The RDF document fragment containing the metadata and referencing the image is shown in Figure 7.

In Figure 7, Line 3 declares namespace aerial which contains the source schema. Lines 5-8 contain the RDF fragment that describes the object-relational schema of table arctic; arctic. imageId contains a unique identifier and arctic. imageValue contains the image itself. Note that only the attributes that are a part of the reference to the image are described; that is, arctic.source is omitted. Lines 9-14 describe the metadata attributes of an aerial photo. They include timestamp, longitude, and latitude. The property reference does not describe a metadata attribute, but rather acts as a reference to the image object.

The source schema is shown in Figure 8. Lines 4-12 define class imageLocation with properties key and value. Lines 13-29 define class image

with properties timestamp, longitude, latitude and reference. Every time an image is added to the source an RDF fragment conforming to this schema is created and stored in the database. Although each fragment will contain a description of table arctic, this description will be stored only once.

We use the RDFSuite (Alexaki et al., 2000) to store RDF and RDFS data. The RDFSuite provides both persistent storage for the RDF and RDFS data and the implementation of the RQL language. The RDFSuite translates RDF data and schemata into object-relational format and stores them in a PostgreSQL database. The RQL interpreter generates SQL queries over the object-relational representation of RDF data and schema and processes RQL path expressions.

Integration Layer

The integration layer combines all multimedia sources into a single *integrated virtual source*. In the context of this layer, a multimedia source is a *local source* and its source schema is a *local schema*. The integrated virtual source is described by the *global schema*, which is obtained as a result

Figure 8. RDFS schema describing arctic photo metadata

```

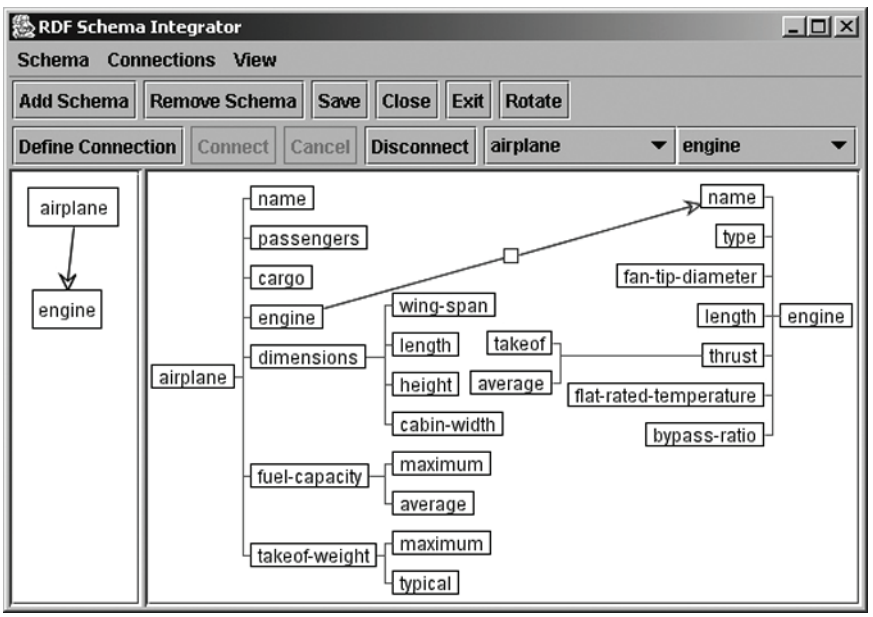
of the integration of the sources. Delaunay^{View} uses foreign key relationships to connect individual sources into the integrated virtual source. Implicit foreign key relationships exist between local sources, but they only become apparent when all local sources are considered as a whole. The global schema is built by explicitly defining foreign key relationships. A sequence of foreign key definitions yields a graph where the local schemata are the subgraphs and the foreign key relationships are the edges that connect them.

The foreign key relationships are defined with the help of the graphical integration tool of Figure 9. This tool provides a simple graphical representation of the schemata that are present in the system and enables the user to specify foreign key relationships between them. When the user imports a source into the system, its schema is represented on the left-hand side panel as a box. Individual schemata are displayed on the right-hand side pane as trees. The user defines a foreign key by selecting a node in each schema that participates in the relationship, and connecting them by an edge. Figure 9 shows how a foreign key relationship is defined between airplane and engine schemata. The edge between engine and name represents that relationship. The graphical integration tool generates an RDF document that describes all the foreign key relationships defined by the user.

The integration layer contains the *mediator engine* and the *schema repository.* The mediator engine receives queries from the presentation layer, issues queries to the data sources, and passes results back to the presentation layer. The schema repository contains the description of the global schema and the mappings from global to local schemata. The mediator engine receives queries in terms of the global schema, *global queries,* and translates them into queries in terms of the local schemata of the individual sources, *local queries*, using the information available from the schema repository. We demonstrate how local queries are obtained by the following example.

Example 2: The engine database and the airplane database are two local sources and engine name connects the local schemata. In the airplane

Figure 9. Graphical integration tool



schema (Figure 10), engine name is a foreign key and is represented by the property power-plant and in the engine schema (Figure 11) it is the key and is represented by the property name. Mappings from the global schema (Figure 12) to the local schema have the form ([global name], ([local name], [local schema])). We say that a class or a property in the global schema, *x*, maps to a local schema *S* when *(x, (y, S))* is in the set of the mappings. For this example, this set is:

(airplane, (airplane, S_1)),
(type, (type, S_1)),
(power-plant, (power-plant, S_1)),
(power-plant, (name, S_2)),
(engine, (engine, S_2)),
(thrust, (thrust, S_2)),
(name, (name, S_2))

All the mappings are one-to-one, except for the power-plant property that connects the two schemata; power-plant belongs to a set of foreign key constraints maintained by the schema repository. These constraints are used to connect the set of results from the local queries.

Figure 10. Airplane schema S1

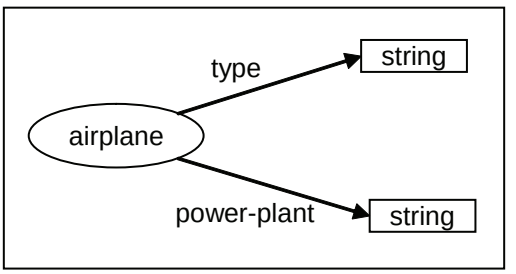


Figure 11. Engine schema S2

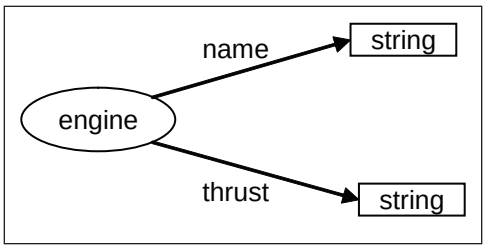

Figure 12. Global schema

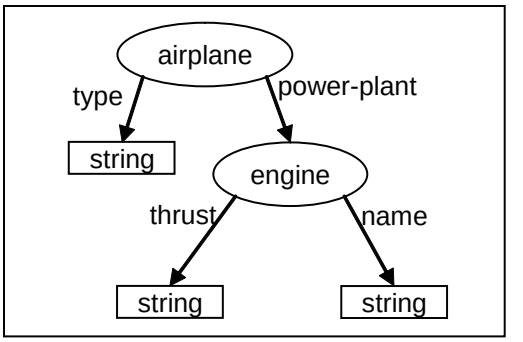

The global query Q^G returns the types of airplanes that have engines with thrust of 115,000 lb:

```
select B
from {A}type{B}, {A}power-plant{C},
{C}thrust{D}
where D = "115000 lbs"
```

The mediator engine translates Q^G into Q^L_1, which is a query over the local schema S_1, and Q^L_2, which is a query over the local schema S_2. The *from clause* of Q^G contains three path expressions: {A}type{B}, which contains property type that maps to S_1 , {A}power-plant{C}, which contains property power-plant that maps both to S_1 and to S_2 , and {C}thrust{D}, which contains property thrust that maps to S_2 .

To obtain the *from clause* of a local query, the mediator engine selects those path expressions that contain classes or properties that map to the local schema. The *from clause* of Q^L_1 is: {A}type{B}, {A}power-plant{C}. Similarly, the *where clause* of a local query contains only those variables of the global *where clause* that appear in the local *from clause*. *D*, which is the only variable in the global *where clause*, does not appear in the *from clause* of Q^L_1, so the *where clause* of Q^L_1 is absent.

The *select clause* of a local query includes variables that appear in the global *select clause* and in the local *from clause*. *B* is a part of the global *select clause* and it appears in the *from clause* of Q^L_1, so it will appear in the *select clause* as well. In addition to the variables from the global *select clause*, a local *select clause* contains variables that are necessary to perform a join of the local results in order to obtain the global result. These are the variables is the local *from clause* that refer to elements of the foreign key constraint set. *C* refers to the value of power-plant, which is the only foreign key constraint, so *C* is included in the local *select clause*. Therefore, Q^L_1 is as follows:

```
select B, C
from {A}type{B}, {A}power-plant{C}
```

The *from clause* of Q^L_2 should include {A}power-plant{C} and {C}thrust{D}; power-plant maps to name and thrust maps to thrust in S_2. Since *D* in the global *where clause* maps to S_2, the local *where clause* contains *D* and the associated constraint: *D* = "115000 lbs". The global *select clause* does not contain any variables that map to S_2, so the local *select clause* contains only the foreign key constraint variable *C*. The intermediate version of Q^L_2 is:

```
select C
from {C}thrust{D}, {A}power-plant{C}
where D = "115000 lbs"
```

The intermediate version of Q^L_2 contains {A}power-plant{C} because power-plant maps to name in S_2. However, {A}power-plant{C} is a special case because it is a foreign key constraint: we must check whether variables A and C refer to resources that map to S_2. A refers to airplane, therefore it does not map to S_2 and {A}power-plant{C} should be removed from Q^L_2. The final version of Q^L_2 is:

```
select C
from {C}thrust{D}
where D = "115000 lbs"
```

In summary, the integration layer connects the local sources into the integrated virtual source and makes it available to the presentation layer. The interface between the integration and presentation layers includes the global schema provided by the integration layer, the queries issued by the presentation layer, and the results returned by the integration layer.

Presentation Layer

The *presentation layer* enables the user to query the distributed multimedia sources and to create complex multicomponent coordinated layouts to display the query results. The presentation layer sends user queries to the integration layer and receives the *data sets*, which are the query results. A *view* is created when a data set is attached to a presentation template that determines how the images in the data set are to be displayed. The user specifies the position and the orientation of the view and the dynamic interaction properties of views in the integrated layout.

Images and metadata are retrieved from the multimedia sources by means of RQL queries to the RDF multimedia annotations stored at the local sources. In addition to RQL queries, the user may issue keyword searches. A keyword search has three components: the keyword, the criteria, and the source. Any of the components is optional. A keyword will match the class or property names in the schema. The criteria match the values of properties in the metadata RDF document. The source restricts the results of the query to that multimedia source. The data sets returned by the integration layer are encapsulated in the *data descriptors* that associate the query, layout, and view coordination information with the data set. The following example illustrates how a keyword query gets translated into an RQL query:

Figure 13. Translation of a keyword search to an RQL query

```
1    SELECT DISTINCT kwResource
2    FROM {kwResource}^@kwProperty{kwValue},
3     {$kwClass}@kwProperty{$rangeClass}
4    WHERE ($kwClass LIKE "*airplane*" OR @kwProperty LIKE "*airplane*")
5            AND kwValue LIKE "*Boeing"
```

Example 3: The keyword search where keyword = "airplane", criteria = "Boeing", and source = "aircraftDataSource" returns resources that are of class "airplane" or have a property "airplane," have the property value "Boeing," and are located in the source "aircraftDataSource". This search is translated into the RQL query of Figure 13 and sent to source aircraftDataSource by the integration layer.

Delaunay^{View} includes predefined presentation templates that allow the user to build customized views. The user chooses attributes of the data set that correspond to template visual attributes. For example, a view can be defined by attaching the arctic photo dataset (see Example 1) to the *slide sorter* template, setting the *order-by* property of the view to the timestamp attribute of the data set, and setting the *image source* property of the view to the reference attribute of the data set. When a tuple in the data set is to be displayed, image references embedded in it are resolved and images are retrieved from multimedia sources.

The user may further customize views by specifying their orientation, position relative to each other, and coordination behavior. Views are coordinated by specifying a relationship between the *initiating view* and the *destination view.* The initiating view notifies the destination view of *initiating events.* An initiating event is the change of view state caused by a user action; selecting an image in a slide sorter, for example.

The destination view responds to initiation events by changing its own state according to the *reaction model* selected by the user. Each template defines a set of initiating events and reaction models.

In summary, semantics play a central role in Delaunay^{View} architecture. The data layer makes semantics available as the metadata descriptions and the local schemata. The integration layer enables the user to define the global schema that adds to the semantics provided by the data layer. The presentation layer uses semantics provided by the data and integration layers for source querying, view definition, and view coordination.

FUTURE WORK

Our future work will further address the decentralized nature of the data layer. Delaunay^{View} can be viewed as a single node in a network of multimedia sources. This network can be considered from two different points of view. From a centralized perspective, the goal is to create a single consistent global schema with which queries can be issued to the entire network as if it were formed by a single database. From a decentralized data acquisition point of view, the goal is to answer a query submitted at one of the nodes. The network becomes relevant when data are required that are not present at the local node.

In the centralized approach, knowledge of the entire global schema is required to answer a query while in the decentralized approach only the knowledge of paths to the required information is necessary. In the centralized approach, the global schema is static. Local sources are connected to each other one by one, resulting in the global schema that must be modified when a local schema is changed. Under the decentralized approach, the integration process can be performed at the

time the query is created (automatically in an ideal system) by discovering the data available at the other nodes. A centralized global schema must resolve inconsistencies in schema and data in a globally optimal manner. Under the decentralized approach inconsistencies have to be resolved only at the level of that node.

The goal of our future work will be to extend Delaunay^{View} to a decentralized peer-to-peer network. Under this architecture, the schema repository will connect to its neighbors to provide schema information to the mediator engine. Conceptually, a request for schema information will be recursively transmitted throughout the network to retrieve the current state of the distributed global schema, but our implementation will adapt optimization techniques from the peer-to-peer community to make schema retrieval efficient. The implementation of the mediator engine and the graphical integration tool will be modified to accommodate the new architecture.

Another goal is to incorporate MPEG-7 *Feature Extraction Tools* into the framework. Feature extraction can be incorporated into the implementation of the graphical integration tool to perform automatic feature extraction on the content of the new sources as they are added to the system. This capability will add another layer of metadata information that will enable users to search for content by specifying low-level features.

CONCLUSIONS

We have discussed our approach to multimedia presentation and querying from a semantic point of view, as implemented by our Delaunay^{View} system. Our paper describes how multimedia semantics can be used to enable access to distributed multimedia sources and to facilitate construction of coordinated views. Semantics are derived from the metadata descriptions of multimedia objects in the data layer. In the integration layer, schemata that describe the metadata are integrated into a single global schema that enables users to view a set of distributed multimedia sources as a single unified source.

In the presentation layer, the system provides a framework for creating customizable integrated layouts that highlight semantic relationships between the multimedia objects. The user can retrieve multimedia data sets by issuing RQL queries or keyword searches. The datasets thus obtained are mapped to presentation templates to create views. The position, the orientation, and the dynamic interaction of views can be interactively specified by the user. The view definition process involves the mapping of metadata attributes to the graphical attributes of a template. The view coordination process involves the association of metadata attributes from two datasets and the specification of how the corresponding views interact. By using the metadata attributes, both the view definition and the view coordination processes take advantage of the multimedia semantics.

Chapter 4.6
OntoMedia:
Semantic Multimedia Metadata Integration and Organization

Bodo Hüsemann
Informationsfabrik GmbH, Münster, Germany

Gottfried Vossen
University of Münster, Germany,
University of Waikato, New Zealand

ABSTRACT

Digital multimedia devices for private usage have nowadays left their analogous counterparts behind. Our homes increasingly incorporate a digital communication infrastructure for interconnecting their various devices inside the house, and this infrastructure also gives access to external information via the Internet. Thus, we now store much of our personal information in digital form and information services like newspaper, radio, or TV are digitally available. The capacity of digital storage devices provides enormous space at affordable prices to save all this digital information into a giant personal multimedia archive; however, as is well known, the more data we store, the less information we have at our disposal. In this article, an approach to personal information management is described that is based on Semantic Web technology. In particular, the design decisions behind, and core features of OntoMedia, a software system based on a multimedia ontology that is intended for personal usage, are presented. OntoMedia supports users organizing personal multimedia archives using ontology powered metadata extraction and integration technology. The application includes a novel, easy to use graphical user interface to organize documents in categories and browse/query the semantic database.

INTRODUCTION

Digital multimedia devices for private usage, including digital cameras, camcorders, or mp3 players, have nowadays left their analogous counterparts behind. Our homes increasingly incorporate a digital communication infrastructure for interconnecting their various devices inside the house, and this infrastructure also gives access to external information via the Internet. Thus,

we now store much of our personal information in digital form and information services like newspaper, radio, or TV are digitally available. The capacity of digital storage devices provides enormous space at affordable prices to save all this digital information into a giant personal multimedia archive (cf. the MyLifeBits project, see Gemmell, Bell, & Lueder, 2006); however, as is well known, the more data we store, the less information we have at our disposal. In this article, we describe an approach to personal information management that is based on Semantic Web (Berners-Lee, Hendler, & Lassila, 2001) technology. In particular, we present the design decisions behind and core features of *OntoMedia*, a software system based on a multimedia ontology that is intended for personal usage. *Personal information management* (PIM) refers to all activities related to the creation, storage, organisation, use, and retrieval of digital information in a personal usage-context. In this article, we focus digital information represented by multimedia documents like digital images, music, texts, or video recordings.

The creation and storage of digital content was never easier, but with increasing volume, the management of multimedia archives turns out to be a non-trivial task with vital research problems. Indeed, ACM's SIGMM ranks "to make capturing, storing, finding, and using digital media an everyday occurrence in our computing environment" one of three major goals for multimedia research for the future (Rowe & Jain, 2005).

With the software application OntoMedia, we address this vision to ease the management of multimedia archives for private users and personal usage (Hüsemann & Vossen, 2004). We have developed this application with two main goals in mind:

1. Automatic extraction and semantic integration of multimedia metadata should be supported.
2. Organisation and search of multimedia documents based on semantic metadata is a necessity.

With *multimedia metadata*, we denote every form of digital information about some multimedia document. The enabling technology to integrate, process, and query metadata for multimedia is delivered by current languages and tools of the Semantic Web.

In Figure 1, we exhibit the schematic evaluation of a user query searching for an instance of concept "person," where the OntoMedia Core Ontology is used to determine semantic relationships to similar concepts in multimedia metadata or the Semantic Web. Basically, this kind of semantic inference is used by OntoMedia to find files related to semantic queries given by the user.

The article is organised as follows: In the second section we briefly review related work. In the third section we describe the OntoMedia application from a user's point of view, and we also explain its system architecture. In the fourth section we study metadata generation and import, and in the fifth section we look at search processes within OntoMedia. With the sixth section, we discuss or experiences with OntoMedia and our approach in general. Finally, we draw some conclusions in the seventh section.

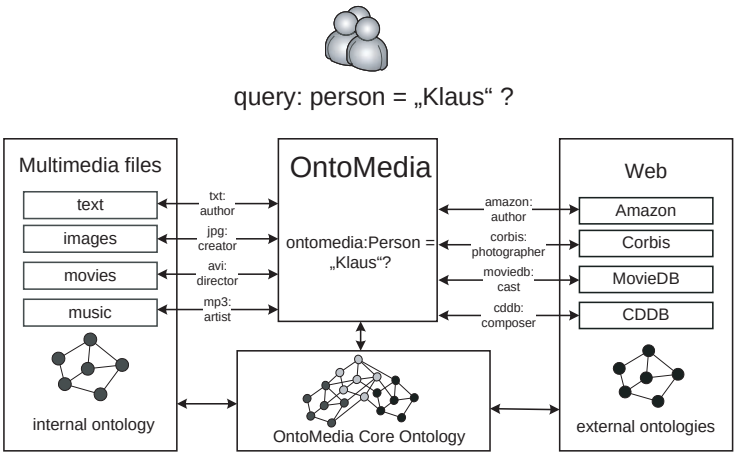
RELATED WORK

The extraction and integration of multimedia metadata has been a central goal for various information systems in the past up to the current hype for desktop indexing and search tools for private users. We summarise the functionality of those systems by the following core features:

- Metadata generation
- Document classification
- Document retrieval

Metadata generation (Handschuh & Staab, 2003) is done with automatic indexing techniques or by manual annotation. There are three different approaches to get metadata for multimedia

Figure 1. Semantic metadata integration with the OntoMedia Core Ontology



documents with software systems: the first approach is content driven where metadata is computed by content analysis mechanisms (e.g., natural language processing of audio data). This analysis produces, for example, text extracts for text documents (Appelt, Hobbs, Bear, Israel, & Tyson, 1993), colour histograms for images (Bimbo, 1999), or frequency histograms for music (Foote, 1997).

The second approach simply extracts already present metadata from a document which is included as part of the document container. This metadata is typically some sort of textual attribute value description for a document. The third is to query external information sources for metadata about a document. This ideally requires a unique identification technique for multimedia documents (e.g., some content dependent hash value, cf. Cano, Batlle, Kalker, & Haitsma, 2005) which can be used to query an external service to retrieve metadata for a document.

For huge personal multimedia archives, manual metadata annotation is very time consuming and content analysis for multimedia documents other than texts is rather ineffective. Thus, OntoMedia follows the second alternative, building a database by automatic metadata extraction. In this article, we will show how we use ontologies to define semantic relations between metadata attributes of different document types with concepts of the multimedia core ontology.

Document classification is a method to associate classes (= categories) with documents. All documents inside a class build a homogeneous set according to some classification criteria. With OntoMedia, we use an ontology-based classification method where documents are directly classified using their metadata. Additionally, the inherent semantics of the ontology provides indirect classifications, which the user can use to query the database. Thus, users can query the database using well-known concepts of the multimedia ontology. Additionally, users manually classify documents and personalise classification structures as they like.

Finally, document retrieval methods select relevant documents of a set of documents according to some retrieval criteria given, for example, by a user defined query. The novel document retrieval feature of OntoMedia is its graphical user interface that supports users to query the database using classes of the multimedia ontology. Users can select a collection of categories with a graphical representation of the ontology and define metadata filters based on properties to search for documents. Given that, OntoMedia

will search for related documents using the formal semantics of the multimedia ontology.

At present, users typically arrange their multimedia collections in file systems, which provide poor naming mechanisms and hierarchical directory structures for organisation and search. Although this approach looks sufficient at first sight there are many problems involved which complicate the management of large multimedia collections (Hüsemann & Vossen, 2004):

- The logical organisation is bound to the underlying physical storage system.
- Categorisation is limited to strict classification hierarchies based on directory structures.
- Document-inherent metadata (e.g., ID3 tags in MP3 files) remains unused and is only available to media-specific applications (e.g., an MP3 player).
- Identification based on file names alone is often not globally consistent (e.g., duplicates are possible).

To overcome these problems, desktop indexing tools try to help users with searching for files. In Table 1, we summarise the functionality provided by desktop indexing tools that are currently available and compare those with OntoMedia.

The tools shown in Table 1 do not support personalised categorisation structures to manu-

ally classify, browse, and search file collections. Along with the automatic classification features of OntoMedia, users can build up their own categorisation structures that can be browsed to categorise and search for files. Thus, users don't need additional software anymore to annotate (e.g., photo-archives by keywords). The categorisation graph of OntoMedia is independent of physical storage structures and not limited to simple hierarchies. Sub-categories can have more than one super-category, which allows for much more powerful organisation structures.

In contrast to the applications shown that use proprietary indexing formats, we use standardised languages of the Semantic Web, which allow for semantic integration of metadata. OntoMedia features a multimedia core ontology to describe all metadata attributes and their semantic connection to enable metadata search processes. The whole information is stored with non-proprietary Resource Description Format (RDF) (cf. Becket, 2004; Lassila & Swick, 2004), which can be exchanged with other Semantic Web enabled applications. Furthermore, the database includes search facilities which feature semantic reasoning capabilities to support the user while searching for relevant attributes inside the ontology. After indexing, OntoMedia initially classifies all documents by rebuilding the current directory structures in the category graph as basis.

ONTOMEDIA FROM A USER'S PERSPECTIVE

In this section, we will use the main user interface of OntoMedia for a guided tour to the functionality of the application. The main user interface of OntoMedia is divided into six different parts shown in Figure 2.

The main part of the user interface between status and menu bar is divided into four different areas where the left half shows schema information of the current ontology and the right half shows instance data about indexed documents in the database.

The left hand side shows the category graph (area 2) and the metadata properties (area 4) of the OntoMedia database. The category graph is a visualisation of the class hierarchy given by the multimedia ontology to categorise files with OntoMedia. The user can navigate, select, and modify the category graph in order to search or organise document collections. The different colours of categories denote different select modes we will explain in detail later. In area 4 (below the category graph), users can define metadata-based search criteria using the displayed metadata property tree. The user can navigate all metadata properties available in the database and define search criteria to filter the results of a search request.

On the right hand side, the user interface shows a tabular listing of files (the file browser) in the

Figure 2. Overview of the OntoMedia user interface

database (area 3), and a playback panel with further file specific details (area 5). The file listing contains all files relevant to the current selection of categories and defined filter criteria. The File Viewer area contains different panels to display all metadata about a selected file, display a set of images, or playback audio/video files selected in the File Browser/Basket.

The menu and toolbar at the top of the user interface (cf. area 1 in Figure 2) provides access to the main functionality concerning data import/export, organisation, and search commands available to the user. The user can export the database in RDF/XML format or import any RDF data to the current database. Thus it is possible to include any RDF based information which is useful (e.g., to import external databases to OntoMedia). The status bar contains information about the current size of the database, and the memory resources used by OntoMedia.

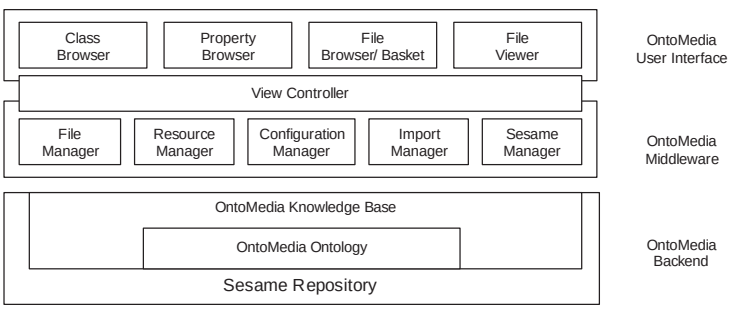
We next give an overview to the software architecture of OntoMedia and some of its external components. The main architecture of OntoMedia is broken down into three major layers that are *user interface*, *middleware*, and *backend*. In principle these parts, which are shown in Figure 3, build a classical three-tier architecture, where all parts could be physically distributed.

Backend: The backend layer performs the centralised data management of the application, which is realised by an external component: the Sesame RDF framework (Broekstra, Kampman, & Harmelen, 2002). The Sesame Framework provides a storage and inference abstraction layer for RDF data. The framework supports different physical data storage options, where users can choose to query and store RDF repositories with memory model stores, native file based stores, or with conventional object relational databases. The backend is completely implemented by Sesame, and can reside on a separate physical system in a multi user environment.

Middleware: The middleware layer of OntoMedia implements high level services of the application which include:

- **File management:** The File Manager provides physical abstraction of files and paths.
- **Configuration management:** the Configuration Manager gives persistent access to global parameters and variables of the application.
- **Resource management:** The Resource Manager is a background process which provides several runtime monitoring services (memory usage, database statistics) to the application.
- **Import management:** The Import Manager handles import processes of the application in a separate thread. It invokes the necessary extractor plugins to scan files for inherent

Figure 3. Overview of the OntoMedia software architecture



metadata, and delivers extracted metadata to the Sesame Manager.

- **Sesame management:** The Sesame Manager is the central access service of the middleware to the OntoMedia backend. The Sesame Manager is subdivided in:
  - Connection Manager to provide physical connection to the backend.
  - Update Manager to perform services with write access to the database.
  - Query Manager to deliver read services evaluating query request.

User Interface: The User Interface Layer (UIL) of OntoMedia consists of several components to browse/query the database and display information about files in the database with related metadata. The UIL is connected to the OntoMedia middleware with the View Controller. The View Controller is a central manager for all user interactions, which need complex process control and communication with the middleware. It delegates queries and changes requests to the backend and handles high level services requests of the UIL through invocation of the other middleware services available.

In detail, the UIL consists of the following main components:

- **Class Browser:** The Class Browser displays a graphical representation of the category hierarchy, and is based on the graphic framework Touchgraph (http://www.touchgraph.com/). The nodes of the graph represent categories, which are connected via directed edges, where edges point from sub categories to super categories. The graph is a non-strict poly hierarchy where sub categories potentially relate to several super categories but form no cycles.

  The Class Browser component uses a spring layout algorithm (Eades, 1984) to display the category graph, which maintains good readability with complex graphs. The layout strategy calculates graph animation based on a force model, where the edges between nodes form ideal rubber bands to drag them to an overall balanced state.

  In Figure 4, we see a simple category graph where the root of the hierarchy is denoted "***" (cf. node 1 in step A).

  The figure illustrates navigation through the animated graph in four subsequent steps A to D, where numbers show the order of category selections in time done by the user. As the user selects a category in the graph, the system expands all its sub categories. To focus the animation on categories of interest the system collapses all categories in the graph which are not part of selected path.

  The user can modify the category graph to fit personal needs, and thus build up own organisation structures which will be discussed in detail later.
- **Property Browser:** The Property Browser component shows the available metadata properties and their hierarchical relation in a tree representation. The property tree is a hierarchical representation of the property hierarchy of the OntoMedia Core Ontology (OMCO). The user can specify property filters by exploring the tree for relevant properties, and defining filter criteria using textual search patterns. In Figure 5, the user has specified a filter "*fire*" on the attribute "External Metadata," and browses the property "Artist" for available values in the database.
- **File Browser/ Basket:** The File Browser shows a tabular listing of files and their associated metadata in the database. The columns of the File Browser represent selected properties of the OMCO, which contain available information to every entry in the current list. The user can change the displayed columns of the table via drag & drop and is able to define property sets,

Figure 4. Navigation of the category hierarchy with the Class Browser

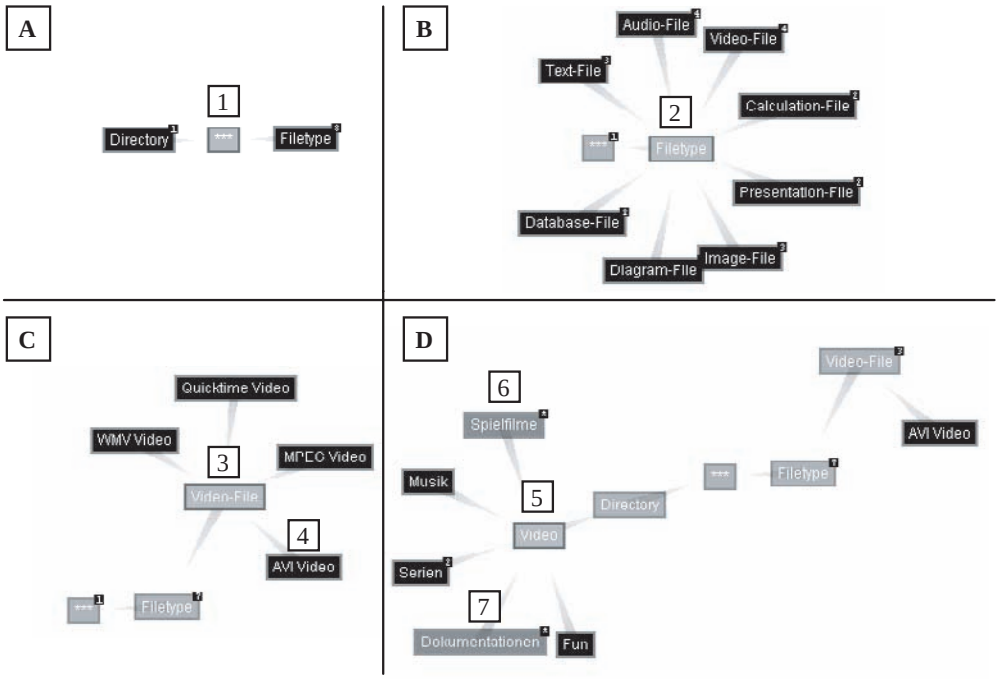


Figure 5. Definition of filter criteria with the Property Browser

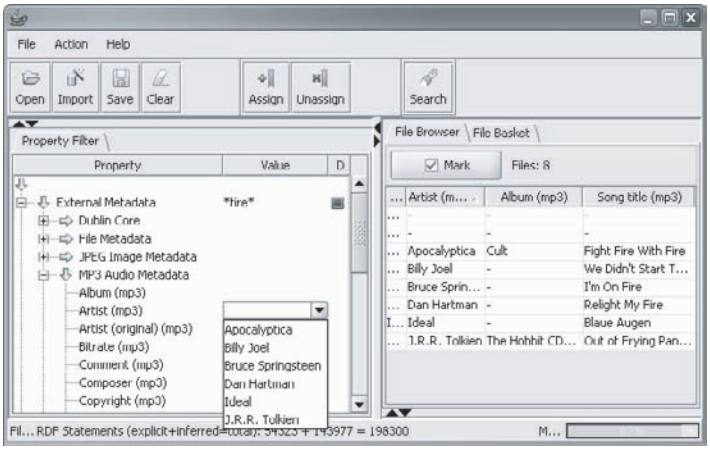


which can be related to hotkeys for quick reference. To change the display of the listing, the user can sort the table by multiple columns or change their order. In addition is possible to group all entries in table by a choosing a grouping property column. The table shows multi valued properties by drop down lists inside the cells. The second file listing available (called File Basket) is a convenience control to help users building file collections with OntoMedia. Users can add selected files from the File Browser to the File Basket in order to iteratively build up file sets with multiple search processes.

- **File Viewer:** After selecting files with the File Browser users choose between dif-

ferent viewers to show more details about associated metadata and their contents. The following components are available:

- **Metadata Viewer:** The metadata viewer shows a list of all available metadata for a selected file. The list shows multi-valued properties with drop down boxes. This list is read only at the moment, but will provide modify access in future versions of OntoMedia.
- **Multimedia Viewer:** The multimedia viewer contains different controls to playback audio and video contents. OntoMedia supports playback of Quicktime, DivX, and MPEG video files within the application using the Java Media Framework (JMF) (http://java.sun.com/products/java media/jmf/index.jsp), and the QuickTime Java SDK (http://www.apple.com/quicktime/qtjava) in conjunction with 3vix decoders (http://www.3ivx.com/). As for audio contents OntoMedia makes use of the JLayer (http://www.javazoom.net/javalayer/javalayer.html) library to play MPEG 1 Layer 3 (MP3) contents. Other uncompressed formats (like WAVE) are handled by JMF. The multimedia viewer includes controls to manage playback queues, volume, and full screen playback.
- **Image viewer:** The image viewer provides simple browsing functionality of image collections in a customisable thumbnail view. The user can control the size of images in the list and switch to a full screen slideshow.

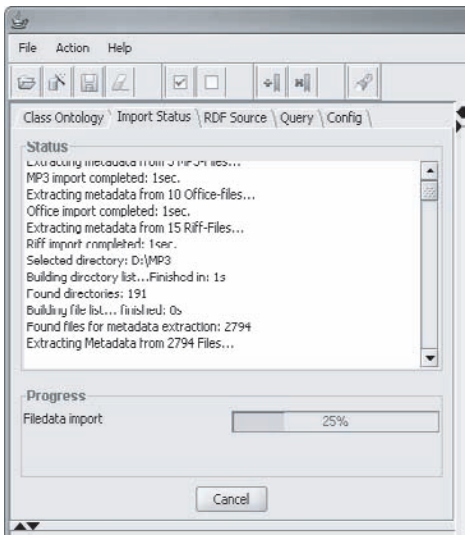
METADATA GENERATION AND IMPORT

Manual annotation of files with metadata is a very time consuming task for voluminous collections. Thus, OntoMedia provides automatic metadata extractors for many file formats, which scan files for included format specific metadata. Once files are scanned with OntoMedia, they can be found by searching the indexed metadata in the database using the OMCO.

The generation and import of metadata is triggered by the user via the tool bar and follows a simple sequential three-step process coordinated by the Import Manager:

1. **Definition of the import task:** The user chooses a directory for the scan process within a conventional file dialog. The system generates an import task for that directory.
2. **Task analysis and preparation:** The selected directory is scanned recursively for files including all inherent subdirectories.

Figure 6. Import status panel which reports progress of metadata import tasks



Every file in the generated file list is queued according to its filename extension to work lists for registered metadata extractors, which can handle files with that extension.

3. **Task processing:** The Import Manager invokes all responsible extractors to process their work list. Every metadata extractor scans all files in its work list for metadata and reports its progress to the import status panel (cf. Figure 6). The extracted metadata will be transformed and integrated according to the OMCO. In the end all extracted, transformed, and integrated metadata is delivered to the Sesame Manager and stored in the database.

The metadata included with files needs to be transformed by an extractor into RDF-based description triples and semantically integrated with the OMCO. For the semantic integration of the imported metadata, the current set of extractors use mappings from specific import ontologies to the OMCO.

In Figure 7, we see a sample of an RDFS import ontology defined by the MP3 metadata extractor used by OntoMedia. The example uses XML entities to encode URL references in XML attribute values where the entity &mp3; (cf. line 1) points to the namespace http://www.ontomedia.de/mp3 of the mp3 extractor and &omco; (cf. line 3) references the OMCO namespace http://www.ontomedia.de/omco. The ontology defines the property &mp3;#copyright which is mapped to the OMCO property &omco;#copyright through the specification of a RDFS subPropertyOf relation (cf. line 3). In addition to this semantic mapping rule the mp3 extractor defines an own application specific RDF property <conv:name> (cf. line 4) which contains a mapping to proprietary attribute name "Copyright" reported by the used mp3 extraction library API. Thus all necessary mappings are defined outside the application code using standardised ontology languages which can be easily processed by RDF aware standard software.

We mention that we have discussed the design of the ontology underlying OntoMedia in an earlier paper (Hüsemann & Vossen 2005).

INFORMATION SEARCH IN ONTOMEDIA

In this section, we will give an introduction to the organisation and search functionality build in with OntoMedia. There are three different types of main management activities, which users will typically invoke with OntoMedia:

1. **Management of categorisation structures:** Users can organise file collections in categories using the category browser. With the management functionality of the category browser, the user can adapt the category graph to their personal needs.

Figure 7. Definition of the RDF property "&mp3;#copyright" and its mapping to OMCO property "&omco;#copyright"

```
1.<rdf:Property about="&mp3;#copyright">
2. <rdfs:subPropertyOf rdf:resource="&mp3;#mp3Metadata"/>
3. <rdfs:subPropertyOf rdf:resource="&omco;#copyright"/>
4. <conv:name>Copyright</conv:name>
5. <rdfs:range rdf:resource="&xsd;#string"/>
6. <rdfs:domain rdf:resource="&omco;#MP3 Audio"/>
7. <rdfs:label xml:lang="de">Copyright (mp3)</rdfs:label>
8. <rdfs:label xml:lang="en">Copyright (mp3)</rdfs:label>
9.</rdf:Property>
```

2. **File categorisation:** Given a category graph, build with the category browser users can manually assign categories to files and thus building a powerful classification system.
3. **File search:** When users have organised their file collections with OntoMedia, they can access the powerful OntoMedia search facilities using the Category Browser or the Property Filter to search for documents.

We will now look at those core activities in more detail, and we will explain some related conceptual design decisions.

Management of Categorisation Structures

The OMCO ontology used by OntoMedia defines basic categories suitable as a generic starting point for building up personalised organisation structures within the category browser. The management of the category graph with OntoMedia is performed by the following action types: manipulation of categories and manipulation of category relations.

Manipulation of Categories

The first thing with building personal categorisation structures using OntoMedia is to add new categories to the graph. New categories can be inserted by selecting a super category with the mouse and dragging away the new category from the selected one (cf. Figure 8a). While accessing the context menu pointing to a selected category, the user can choose further manipulation actions including commands to rename or delete categories from the graph (cf. Figure 8b). If the user deletes a category from the graph, all categories in the related sub hierarchy will be deleted too.

Figure 8. Manipulation of categories adding new categories: (a) and renaming/deleting categories (b) via context menus

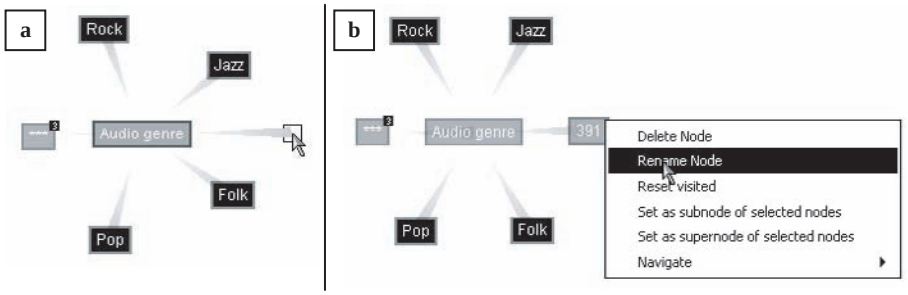


Figure 9. Manipulation of category relations using the context menu to add (a) or delete (b) category relations in the graph

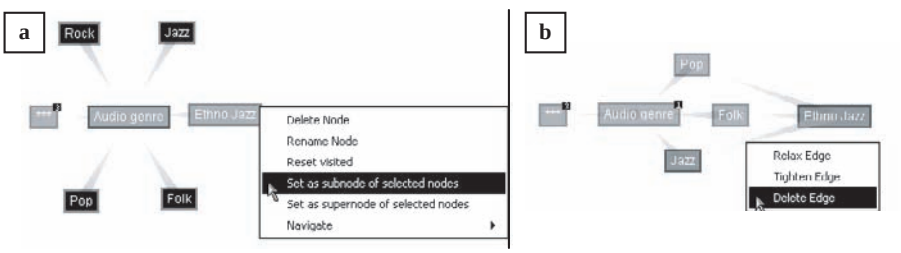


Manipulation of Category Relations

Relationships between categories can be added (cf. Figure 9a) and deleted (cf. Figure 9b) using their context menus in the Category Browser. If the user detaches a sub category from its super category every file in every sub category of the related sub hierarchy will recursively loose its relation to the super category, too.

File Categorisation

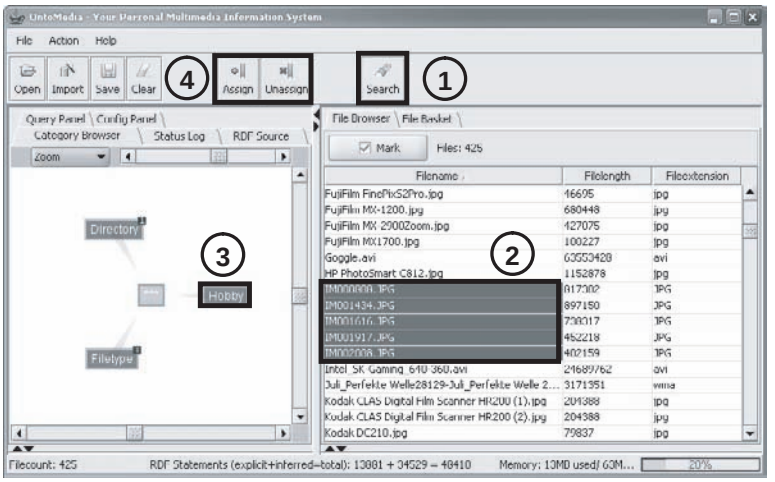
The (de-)categorisation of files with OntoMedia is a simple four step sequential process (cf. Figure 10):

1. **File search:** the user searches for potential relevant files using the file search capabilities of OntoMedia. The File Browser displays the list of all files relevant to the current search criteria defined with the Category Browser and the Property Filter.
2. **File selection:** Using the File Browser or the File Basket users select all files in the current list they want to process within the categorisation process.
3. **Category selection:** The user marks all relevant categories in the graph in order to define the target for the categorisation. All marked categories have red colour in the graph.
4. **Categorisation processing:** With the last step the user triggers the categorisation process by choosing the "Assign" or "Unassign" command in the toolbar.

OntoMedia supports searching in the OntoMedia database by using the Category Browser and the Property Filter to define search criteria. In Figure 11, we can see a simple sequential search process within OntoMedia with the following steps:

1. **Category restriction:** The user restricts the search to a selected set of categories.
2. **Property restriction:** The user specifies textual constraints with the property filter.
3. **Query processing:** The user triggers query evaluation via the search command button.
4. **Result display:** The user retrieves the result which is displayed in the File Browser.

Figure 10. File categorization with OntoMedia



File Search

The user can activate two different select modes in the category browser, which define necessary and optional category for files in the result of a query. All necessary categories are displayed red and all optional categories are displayed green in the graph. Yellow categories get indirectly selected by subcategories or lie on the path to the current active node in the graph. All other categories in the graph have blue colour. In addition to category selections the user can define, textual constrains using the Property Filter in OntoMedia. It is possible to use wildcards in a query indicated by an "*" as commonly used in keyword based retrieval systems.

In Figure 11, we can see the definition of the following sample query with OntoMedia:

Q = "Give me all files which are related to the categories "Audio File" and at least one of the categories "Rock" or "Folk" where the property "Album (mp3) contains the string "the best."

A generic representation of this query using a simple Boolean retrieval model where categorisation is modelled by the attribute "cat" would be as follows:

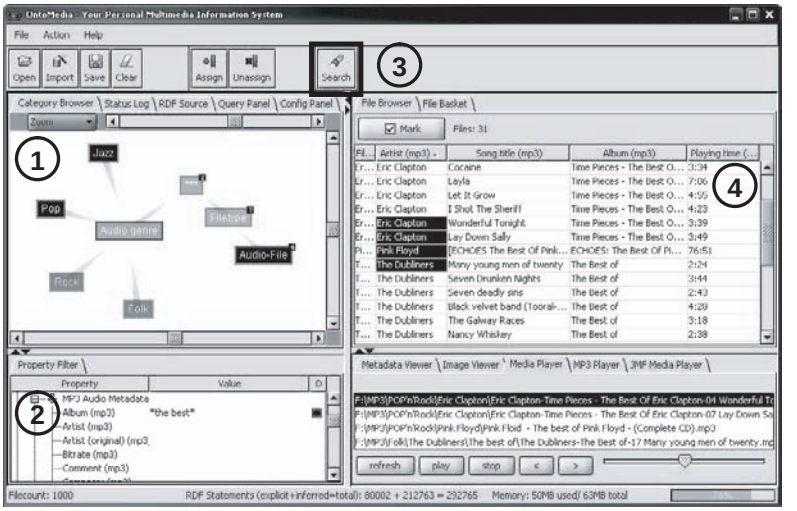
```
Q':= (cat, "Audio File") AND
     ((cat, "Rock") OR (cat, "Folk")) AND
     (Album (mp3), "*the best")).
```

The Sesame Framework uses common RDFS semantics to evaluate queries of OntoMedia. Using RDFS semantics inferencing services will expand user queries to all related sub categories and sub properties defined in a user query using the ontology of the database. If the user queries a super property `artist` the system will expand the query to all related sub properties of artist (e.g., `painter`, `composer`, `and photograph`) too. The same is true for categories where RDFS semantics relates all files in a sub category implicitly to all super categories.

DISCUSSION

OntoMedia is targeted at use case scenarios of private users. We have not done a systematic user evaluation yet, so we will share some general experiences we have gained from conferences and our own use next.

Figure 11. Example search process with OntoMedia



From a functional point, of view users like the category graph to define queries and enjoy its layout animation. Especially non-technical users appreciate the metadata property tree, as they can browse for relevant properties on higher abstraction levels without knowledge of the exact technical denotation typical for detailed metadata.

We consider the graphical user interface very useful to organise medium sized category graphs (< 200 categories, max. 8 levels). If a category has many subcategories (> 30) on the next level the radial layout has disadvantages as we didn't implemented sorting to simplify systematic search by enumeration.

From a technical point of view, we have tested the system with medium-size multimedia archives up to 10,000 files on standard PC equipment. The underlying RDF Framework Sesame performs brilliant at querying persistent memory stores (query evaluation takes less than one second). Nevertheless, the current Sesame implementation has significant performance problems with update operations. So changes of the categorisation graph like deleting categories or modifying document categorisations can be rather slow (update operations can take > 1 minute). Hopefully, the Sesame community will provide some solution to those update performance problems in upcoming releases.

Compared to standard desktop indexing tools, OntoMedia demonstrates the effective use of Semantic Web technology to improve the management of personal multimedia collections. Users can browse the available metadata by exploiting clearly defined semantic relations between available classes and attributes in the multimedia ontology. This approach is much more effective then simple unstructured text queries. The OntoMedia Core Ontology defines a standard vocabulary for the technical properties and content of multimedia. The concepts of the ontology are easy to understand for non-experienced users, which can thus query for documents with an easy to understand vocabulary without expert-knowledge of the metadata included in specific file-formats.

At the moment, OntoMedia targets the multimedia environment of private users while its general architecture and use of Semantic Web technology allows for different usage scenarios, too. We can think of specialised OntoMedia Ontologies for Health Care scenarios, where special extractors index metadata of medical information systems and libraries. Medical staff could use OntoMedia to bridge the semantic gap between different medical databases using a uniform vocabulary to search for documents relevant to specific diseases.

As the manual annotation of documents with metadata is very time consuming, the critical point of the metadata searches in general, and OntoMedia in special, is the quality and amount of metadata available in the documents. If we examine the metadata of MP3-format music, we know that plenty of files are annotated, but the annotation's quality may be poor. Semantic Web technology in itself is not capable to correct the spelling of an artist's name. But along with other technology (e.g., audio fingerprinting to identify music by content analysis) Semantic Web technology provides a standardised platform to describe, exchange, query, and reason about metadata from documents.

CONCLUSION AND OUTLOOK

In this paper, we introduced the application "OntoMedia" which uses Semantic Web technology to implement an ontology driven personal multimedia information system. The main goal of this system was the management of large multimedia collections using semantic integration techniques for metadata by applying state of the art ontology driven Semantic Web technology to the multimedia domain. As compared to competitive systems, OntoMedia provides the following core advantages:

- Semantic metadata integration using standardised ontology languages to define semantic mappings between different ontologies and proprietary formats.
- Semantic query evaluation using inference techniques based on RDFS semantics.
- An innovative graphical user interface using poly hierarchies to organise categorisation structures which provide multiple classifications based on standardised RDFS semantics.
- An overall extensible platform independent architecture which allows for easy data exchange interfaces using RDF as an extensible base for both semantic schema information and instance data.

OntoMedia was built using platform independent Java Technology, which provides an easy test ride of the application without complicated installation procedures using the Java WebStart access point at http://www.ontomedia.de/webstart.

Future versions of OntoMedia will include better access to external metadata sources providing by web databases such as Musicbrainz (http://www.muscibrainz.org), Internet Movie Database (http://www.imdl.org), or FreeDB (http://www.freedb.org). In addition, the current prototype is not well tuned to help personalisation of the presented metadata. We will include usage feedback mechanisms to adapt the presentation of the category graph to user behaviour by statistical analysis. Doing this, OntoMedia will calculate often used navigation paths in the categorisation graph and adapt its presentation of the graph. In addition, we might include content specific indexing functionality in future versions, which will be easy for textual content but is still a problem analyzing audio visual media.

Chapter 4.7
Semantic Multimedia Information Analysis for Retrieval Applications

João Magalhães
Imperial College London, UK

Stefan Rüger
Imperial College London, UK

ABSTRACT

Most of the research in multimedia retrieval applications has focused on retrieval by content or retrieval by example. Since the classical review by Smeulders, Worring, Santini, Gupta, and Jain (2000), a new interest has grown immensely in the multimedia information retrieval community: retrieval by semantics. This exciting new research area arises as a combination of multimedia understanding, information extraction, information retrieval, and digital libraries. This chapter presents a comprehensive review of analysis algorithms in order to extract semantic information from multimedia content. We discuss statistical approaches to analyze images and video content and conclude with a discussion regarding the described methods.

INTRODUCTION: MULTIMEDIA ANALYSIS

The growing interest in managing multimedia collections effectively and efficiently has created new research interest that arises as a combination of multimedia understanding, information extraction, information retrieval, and digital libraries. This growing interest has resulted in the creation of a video retrieval track in TREC conference series in parallel with the text retrieval track (TRECVID, 2004).

Figure 1 illustrates a simplified multimedia information retrieval application composed by a multimedia database, analysis algorithms, a description database, and a user interface application. Analysis algorithms extract features from multimedia content and store them as descriptions of that content. A user then deploys these indexing descriptions in order to search the multimedia

Figure 1. A typical multimedia information retrieval application

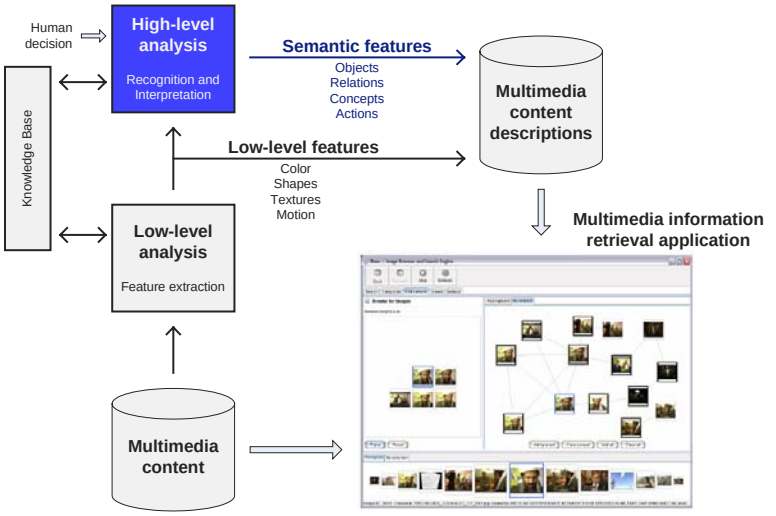

Figure 2. Syntactic and semantic structure of video

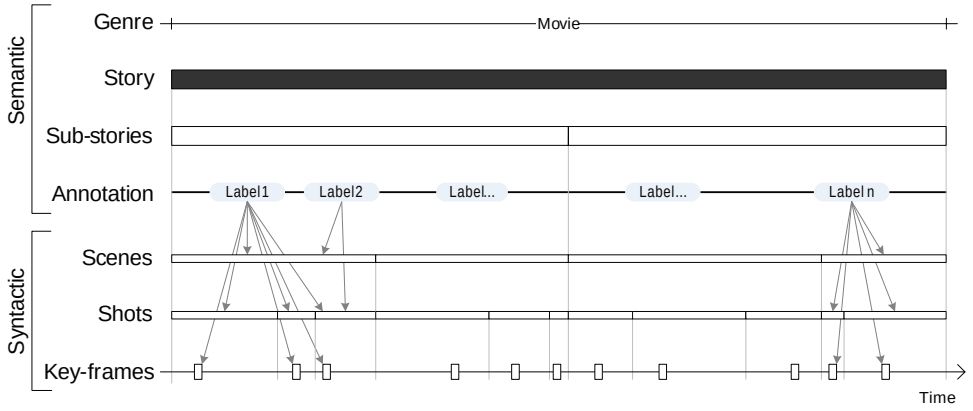


database. A semantic multimedia information retrieval application (Figure 1) differs eminently from traditional retrieval applications on the low-level analysis algorithms; its algorithms are responsible for extracting semantic information used to index multimedia content by its semantic. Multimedia content can be indexed in many ways, and each index can refer to different modalities and/or parts of the multimedia piece. Multimedia content is composed of the visual track, sound track, speech track, and text. All these modalities are arranged temporally to provide a meaningful way to transmit information and/or entertainment.

The way video documents are temporally structured can be distinguished in two levels: semantic and syntactic structure (Figure 2).

At the syntactic level, the video is segmented into shots (visual or audio) that form a uniform segment (e.g., visually similar frames); representative key-frames are extracted from each shot, and scenes group neighboring similar shots into a single segment. The segmentation of video into its syntactic structure of video has been studied widely (Brunelli, Mich, & Modena, 1999; Wang, Liu, & Huang, 2000).

At the semantic level, annotations of the key-frames and shots with a set of labels indicate the presence of semantic entities, their relations, and attributes (agent, object, event, concept, state, place, and time (see Benitez et al., 2002, for details). Further analysis allows the discovery of logical sub-units (e.g., substory or subnarrative), logical units (e.g., a movie), and genres. A recent review of multimedia semantic indexing has been published by Snoek and Worring (2005).

The scope of this chapter is the family of semantic-multimedia analysis algorithms that automate the multimedia semantic annotation process. In the following sections, we will review papers on multimedia-semantic analysis: semantic annotation of key-frame images, shots, and scenes. The semantic analysis at the shot and scene level considers independently the audio and visual modalities and then the multi-modal semantic analysis. Due to the scope of this book, we will give more emphasis to the visual part than to the audio part of the multimedia analysis and will not cover the temporal analysis of logical substories, stories, and genres.

KEY-FRAME SEMANTIC ANNOTATION

Image analysis and understanding is one of the oldest fields in pattern recognition and artificial intelligence. A lot of research has been done since (Marr, 1983), culminating in the modern reference texts by Forsyth and Ponce (2003) and Hartley and Zisserman (2004). In the following sections we discuss different types of visual information analysis algorithms: single class models fit a simple probability density distribution to each label; translation models define a visual vocabulary and a method to translate from this vocabulary to keywords; hierarchical and network models explore the interdependence of image elements (regions or tiles) and model its structure; knowledge-based models improve the model's accuracy by including other sources of knowledge besides the training data (e.g., a linguistic database such as WordNet).

Single Class Models

A direct approach to the semantic analysis of multimedia is to learn a class-conditional probability distribution $p(w \mid x)$ of each single keyword w of the semantic vocabulary, given its training data x (see Figure 3). This distribution can be obtained by using Bayes' law:

$$p(w \mid x) = \frac{p(x \mid w)\, p(w)}{p(x)}.$$

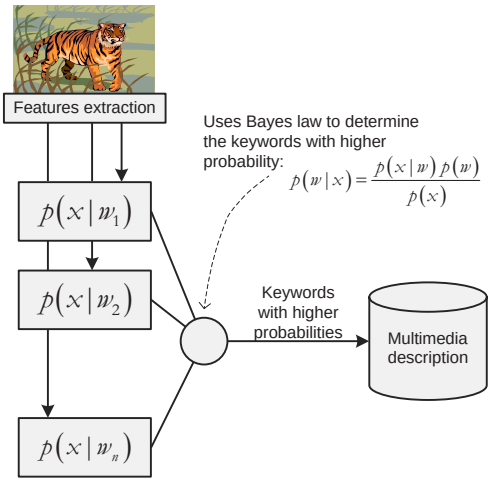
The data probability $p(x)$ and the keyword probability $p(w)$ can be computed straightforward, and the $p(x \mid w)$ can be computed with very different data density distribution models.

Several techniques to model the $p(x \mid w)$ with a simple density distribution have been proposed: Yavlinsky, Schofield, and Rüger (2005) used a nonparametric distribution, Carneiro and Vasconcelos (2005) a semi-parametric density estimation, Westerveld and de Vries (2003) a finite mixture of Gaussians, and Mori, Takahashi, and Oka (1999), Vailaya, Figueiredo, Jain, and Zhang (1999), and Vailaya, Figueiredo, Jain, and Zhang (2001) different flavors of vector quantization techniques.

Yavlinsky et al. (2005) modeled the probability density of images, given keywords as a nonparametric density smoothed by two kernels: a Gaussian kernel and an Earth Mover's Distance kernel. They used both global and 3×3 tile color and texture features. The best reported mean average precision (MAP) results with tiles achieved 28.6% MAP with the dataset of Duygulu, Barnard, de Freitas, and Forsyth (2002) and 9.2% with a Getty Images dataset.

Yavlinsky et al. (2005) showed that a simple nonparametric statistical distribution can perform as well or better than many more sophisticated techniques (e.g., translation models). However, the

Figure 3. Inference of single class models



nonparametric density nature of their framework makes the task of running the model on new data very complex. The model is the entire dataset meaning that the demands on CPU and memory increase with the training data.

Westerveld and de Vries (2003) used a finite-mixture density distribution with a fixed number of components to model a subset of the DCT coefficients:

$$p(x|\theta)=\sum_{m=1}^{k}\alpha_m p(x|\mu_m,\sigma_m^2),$$

in which k is the number of components, θ represents the complete set of model parameters with mean μ_m, covariance σ_m^2, and component prior α_m. The component priors have the constraints $\alpha_1,...,\alpha_k \geq 0$ and $\sum_{m=1}^{k}\alpha_m = 1$. Westerveld (2003) tested several scenarios to evaluate the effect (a) of the number of mixture components, (b) of using different numbers of DCT coefficients (luminance and chrominance), and (c) of adding the coordinates of the DCT coefficients to the feature vectors. The two first factors produced varying results, and optimal points were found experimentally. The third tested aspect, the presence of the coefficients position information, did not modify the results.

Marrying the two previous approaches, Carneiro and Vasconcelos (2005) deployed a hierarchy of semi-parametric mixtures to model $p(x \mid w)$ using a subset of the DCT coefficients as low-level features. Vasconcelos and Lippman (2000) had already examined the same framework in a content-based retrieval system.

The hierarchy of mixtures proposed by Vasconcelos and Lippman (1998) can model data at different levels of granularity with a finite mixture of Gaussians. At each hierarchical level *l*, the number of each mixture component k^l differs by one from adjacent levels. The hierarchy of mixtures is expressed as:

$$p(x|w_i)=\frac{1}{D}\sum_{m=1}^{k^l}\alpha_{i,m}^{l}p(x|\theta_{i,m}^{l}).$$

The level *l=1* corresponds to the coarsest characterization. The more detailed hierarchy level consists of a nonparametric distribution with a kernel placed on top of each sample. The only restriction on the model is that if node *m* of level *l+1* is a child of node *n* of level *l*, then they are both children of node *p* of level *l-1*. The EM algorithm computes the mixture parameters at level *l*, given the knowledge of the parameters at level *l+1*, forcing the previous restriction.

Carneiro and Vasconcelos (2005) report the best published retrieval MAP of 31% with the dataset of Duygulu et al. (2002). Even though we cannot dissociate this result from the pair of features and statistical model, the hierarchy of mixtures appears to be a very powerful density distribution technique.

Even though the approaches by Carneiro and Vasconcelos (2005) and Westerveld and de Vries (2003) are similar, the differences make it difficult to do a fair comparison. The DCT features are used in a different way, and the semi-parametric hierarchy of mixtures can model classes with very few training examples.

The relationship between finite-mixture density modeling and vector quantization is a well-studied subject (see Hastie, Tibshirani, &

Friedman, 2001). One of the applications of vector quantization to image retrieval and annotation was realized by Mori et al. (1999). Given the training data of a keyword, they divide the images into tiles and apply vector quantization to the image tiles in order to extract the codebook used to estimate the $p(x \mid w)$ density distribution. Later, they use a model of word co-occurrence on the image tiles in order to label the image. The words with the higher sum of probabilities across the different tiles are the ones assigned to that image.

Vailaya et al. (1999) and Vailaya et al. (2001) describe a Bayesian framework using a codebook to estimate the density distribution of each keyword. They show that the Minimum Description Length criterion selects the optimal size of the codebook extracted from the vector quantizer. The features are extracted from the global image, and there is no image tiling. The use of the MDL criterion makes this framework quite elegant and defines a statistical criterion to select every model parameter and without any user-defined parameters.

Translation Models

All of the previous approaches employ a direct model to estimate $p(x \mid w)$ with image global features and/or image tiles features. In contrast to this, the vector quantization (usually k-means) approach generates a codebook of image regions or image tiles (depending on the segmentation solution). The problem then is formulated as a translation problem between two representations of the same entity: English-Esperanto, word-blob codebook, or word-tile codebook.

Inspired by machine translation research, Duygulu et al. (2002) developed a method of annotating image regions with words. First, regions are created using a segmentation algorithm like normalized cuts (Shi & Malik, 2000). For each region, features are computed, and then blobs are generated by clustering the regional image features across an image collection. The problem then is formulated as learning the correspondence between the discrete vocabulary of blobs and the image keywords. The model consists of a mixture of correspondences for each word of each image in the collection:

$$p\left(w_j \mid I_n\right) = \sum_{i \in \{\text{blobs in } I_n\}} p\left(a_{nj} = i\right) p\left(w = w_{nj} \mid b = b_i\right),$$

in which $p(a_{nj} = i)$ expresses the probability of associating word j to blob i in image n, and $p(w = w_{nj} \mid b = b_i)$ is the probability of obtaining an instance of word w given an instance of blob b. These two probability distributions are estimated with the EM algorithm. The authors refined the lexicon by clustering indistinguishable words and ignoring the words with probabilities $p(w \mid b)$ below a given threshold.

The machine translation approach, the thorough experiments, and the dataset form strong points of this chapter (Duygulu et al., 2002). This dataset is nowadays a reference, and thorough experiments showed that (a) their method could predict numerous words with high accuracy, (b) increasing the probability threshold improved precision but reduced recall, and (c) the word clustering improved recall and precision.

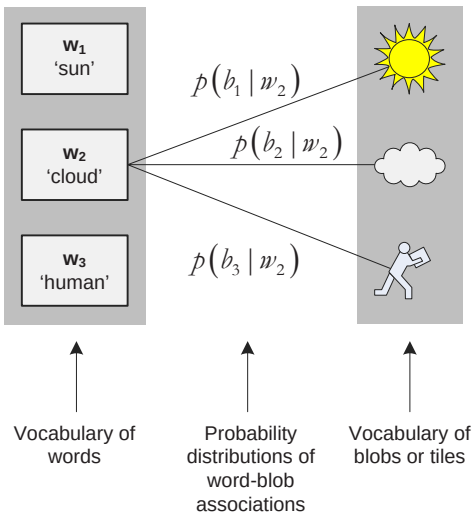
Following a translation model, Jeon, Lavrenko, and Manmatha (2003), Lavrenko, Manmatha, and Jeon (2003), and Feng, Lavrenko, and Manmatha (2004) studied a model in which blob features $b_I^{(r)}$ of an image I are assumed to be conditionally independent of keywords w_i, that is:

$$\begin{aligned} p\left(w_i, b_I\right) &= \sum_{J \in D} P(J) P\left(w_i \mid J\right) P\left(b_I \mid J\right) \\ &= \sum_{J \in D} P(J) P\left(w_i \mid J\right) \prod_{r \in I} P\left(b_I^{(r)} \mid J\right) \end{aligned}$$

Note that $b_I^{(r)}$ and w_i are conditionally independent, given the image collection D and that $J \in D$ act as the hidden variables that generated the two distinct representations of the same process (words and features).

Jeon et al. (2003) recast the image annotation as a cross-lingual information retrieval problem,

Figure 4. Translation models



applying a cross-media relevance model based on a discrete codebook of regions. Lavrenko et al. (2003) continued their previous work (Jeon et al., 2003) and used continuous probability density functions $p(b_l^{(r)} \mid J)$ to describe the process of generating blob features and to avoid the loss of information related to the generation of the codebook. Extending their previous work, Feng et al. (2004) replaced blobs with tiles and modeled image keywords with a Bernoulli distribution. This last work reports their best results, a MAP of 30%, with a Corel dataset (Duygulu et al., 2002).

Latent semantic analysis is another technique of text analysis and indexing; it looks at patterns of word distributions (specifically, word co-occurrence) across a set of documents (Deerwester, Dumais, Furmas, Landauer, & Harshman, 1990). A matrix *M* of word occurrences in documents is filled with each word frequency in each document. The singular value decomposition (SVD) of matrix *M* gives the transformation to a singular space in which projected documents can be compared efficiently.

Hierarchical Models

The aforementioned approaches assumed a minimal relation among the various elements of an image (blobs or tiles). This section and the following section will review methods that consider a hierarchical relation or an interdependence relation among the elements of an image (words and blobs or tiles).

Barnard and Forsyth (2001) studied a generative hierarchical aspect model, which was inspired by Hofmann and Puzicha's (1998) hierarchical clustering/aspect model. The data are assumed to be generated by a fixed hierarchy of nodes in which the leaves of the hierarchy correspond to soft clusters. Mathematically, the process for generating the set of observations O associated with an image I can be described by Box 1, in which c indexes the clusters, o indexes words and blobs, and l indexes the levels of the hierarchy. The level and the cluster uniquely specify a node of the hierarchy. Hence, the probability of an observation $p(o \mid l, c)$ is conditionally independent given a node in the tree. In the case of words, $p(o \mid l, c)$ assumes a tabular form, and in the case of blobs, a single Gaussian models the regions' features. The model is estimated with the EM algorithm.

Blei and Jordan (2003) describe three hierarchical mixture models to annotate image data, culminating in the correspondence latent Dirichlet allocation model. It specifies the following joint distribution of regions, words, and latent variables (θ, z, y):

Box 1.

$$p(O \mid I) = \sum_c \left(p(c) \prod_{o \in O} \left(\sum_l p(o \mid l, c)\, p(l \mid c, I) \right) \right), \quad O = \{w_1, \ldots, w_n, b_1, \ldots, b_m\}$$

$$p(r,w,\theta,z,y)=p(\theta\mid\alpha)\left(\prod_{n=1}^{N}p(z_n\mid\theta)p(r_n\mid z_n,\mu,\sigma)\right)\cdot\left(\prod_{m=1}^{M}p(y_m\mid N)p(w_m\mid y_m,z,\beta)\right).$$

This model assumes that a Dirichlet distribution θ (with α as its parameter) generates a mixture of latent factors: z and y. Image regions r_n are modeled with Gaussians with mean μ and covariance σ, in which words w_n follow a multinomial distribution with a β parameter.

This mixture of latent factors then is used to generate words (y variable) and regions (z variable). The EM algorithm estimates this model, and the inference of $p(w\mid r)$ is carried out by variational inference. The correspondence latent Dirichlet allocation model provides a clean probabilistic model for annotating images with multiple keywords. It combines the advantages of probabilistic clustering for dimensionality reduction with an explicit model of the conditional distribution from which image keywords are generated.

Li and Wang (2003) characterize the images with a hierarchical approach at multiple tiling granularities (i.e., each tile in each hierarchical level is subdivided into smaller sub-tiles). A color and texture feature vector represents each tile. The texture features represent the energy in high-frequency bands of wavelet transforms. They represent each keyword separately with two-dimensional, multi-resolution hidden Markov models. This method achieves a certain degree of scale invariance due to the hierarchical tiling process and the two-dimensional multiresolution hidden Markov model.

Network Models

In semantic-multimedia analysis, concepts are interdependent; for example, if a house is detected in a scene, then the probability of existing windows and doors in the scene are boosted, and vice-versa. In other words, when inferring the probability of a set of interdependent random variables, their probabilities are modified iteratively until an optimal point is reached (to avoid instability, the loops must exist over a large set of random variables [Pearl, 1988]). Most of the papers discussed next model keywords as a set of interdependent random variables connected in a probabilistic network.

Various graphical models have been implemented in computer vision to model the appearance, spatial relations, and co-occurrence of local parts. Markov random fields and hidden Markov models are the most common generative models that learn the joint probability of the observed data (X) and the corresponding labels (Y). These models divide the image into tiles or regions (other approaches use contour directions, but these are outside the scope of our discussion). A probabilistic network then models this low-level division in which each node corresponds to one of these tiles or regions and its label. The relation among nodes depends on the selected neighboring method. Markov random fields can be expressed as:

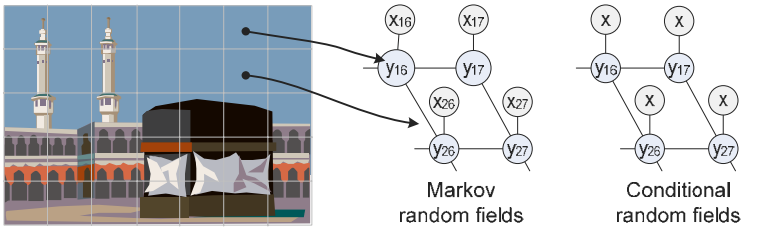
$$P(x,y)=\frac{1}{Z}\cdot\prod_{i}\left(\phi_i(x_i,y_i)\cdot\prod_{j\in N_i}\varphi_{i,j}(y_i,y_j)\right),$$

in which i indexes the image's tiles, j indexes the neighbors of the current i tile, ϕ_i is the potential function of the current tile x_i, and its possible labels y_i, and $\varphi_{i,j}$ are the interaction functions between the current tile label and its neighbors. Figure 5 illustrates the Markov random field framework.

The Markov condition implies that a given node only depends on its neighboring nodes. This condition constitutes a drawback for these models, because only local relationships are incorporated into the model. This makes it highly unsuitable for capturing long-range relations or global characteristics.

In order to circumvent this limitation, Kumar and Herbert (2003a) propose a multi-scale random field (MSRF) as a prior model on the class

Figure 5. Two types of random fields



labels on the image sites. This model implements a probabilistic network that can be approximated by a 2D hierarchical structure such as a 2D-tree. A multiscale feature vector captures the local dependencies in the data. The distribution of the multiscale feature vectors is modeled as a mixture of Gaussians. The features were selected specifically to detect human-made structures, which are the only types of objects that are detected.

Kumar and Herbert's (2003) second approach to this problem is based on discriminative random fields, an approach inspired on conditional random fields (CRF). CRFs, defined by Lafferty, McCallum, and Pereira (2001), are graphical models, initially for text information extraction, that are meant for visual information analysis in this approach. More generally, a CRF is a sequence-modeling framework based on the conditional probability of the entire sequence of labels (Y), given the all image (X). CRFs have the following mathematical form:

$$P(y|x)=\frac{1}{Z}\cdot\prod_{i}\left(\phi_i(y_i,x)\cdot\prod_{j\in N_i}\varphi_{i,j}(y_i,y_j;x)\right),$$

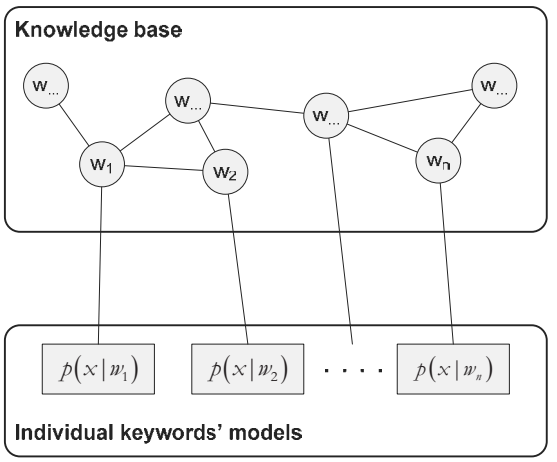
in which i indexes the image's tiles, j indexes the neighbors of the current i tile, ϕ_i is the association potential between the current tile and the image label, and $\varphi_{i,j}$ is the interaction potential between the current tile and its neighbors (note that it is also dependent on the image label). Figure 5 illustrates the conditional random field framework. The authors showed that this last approach outperformed their initial proposal of a multiscale random field as well as the more traditional MRF solution in the task of detecting human-made structures.

He, Zemel, and Carreira-Perpiñán (2004) combine the use of a conditional random field and data at multiple scales. Their multiscale conditional random field (mCRF) is a product of individual models, each model providing labeling information from various aspects of the image: a classifier that looks at local image statistics; regional label features that look at local label patterns; and global label features that look at large, coarse label patterns. The mCRF is shown to detect several types of concepts (i.e., sky, water, snow, vegetation, ground, hippopotamus, and bear) with classification rates better than a traditional Markov random field.

Quattoni, Collins, and Darrell (2004) extend the CRF framework to incorporate hidden variables and combine class-conditional CRFs into a unified framework for part-based object recognition. The features are extracted from special regions that are obtained with the scale-invariant feature transform or SIFT (Lowe, 1999). The SIFT detector finds points in locations at scales in which there is a significant amount of variation. Once a point of interest is found, the region around it is extracted at the appropriate scale. The features from this region then are computed and plugged into the CRF framework. The advantage of this method is that it needs fewer regions by eliminating redundant regions and selecting the ones with more energy on high-frequency bands.

One should note that all these approaches require a ground truth at the level of the image's

Figure 6. Knowledge-based models



tiles/regions as is common in computer vision. This is not what is found traditionally in multimedia information retrieval datasets in which the ground truth exists rather at a global level.

Knowledge-Based Models

The previous methods have only visual features as training data to create the statistical models in the form of a probabilistic network. Most of the time, these training data are limited, and the model's accuracy can be improved by other sources of knowledge. Prior knowledge can be added to a model either by a human expert who states the relations between concept variables (nodes in a probabilistic network) or by an external knowledge base in order to infer the concept relations (e.g., with a linguistic database such as WordNet) (Figure 6).

Tansley (2000) introduces a multimedia thesaurus in which media content is associated with appropriate concepts in a semantic layer composed by a network of concepts and their relations. The process of building the semantic layer uses Latent Semantic Indexing to connect images to their corresponding concepts, and a measure of each correspondence (image concept) is taken from this process. After that, unlabeled images (test images) are annotated by comparing them with the training images using a *k*-nearest-neighbor classifier. Since the concepts' interdependences are represented in the semantic layer, the concepts' probability computed by the classifier are modified by the others concepts.

Other authors have explored not only the statistical interdependence of context and objects but also have used other knowledge that is not present in multimedia data, which humans use to understand (or predict) new data. Srikanth, Varner, Bowden, and Moldovan (2005) incorporated linguistic knowledge from WordNet (Miller, 1995) in order to deduce a hierarchy of terms from the annotations. They generate a visual vocabulary based on the semantics of the annotation words and their hierarchical organization in the WordNet ontology.

Benitez and Chang (2002) and Benitez (2005) took this idea further and suggested a media ontology (MediaNet) to help to discover, summarize, and measure knowledge from annotated images in the form of image clusters, word senses, and relationships among them. MediaNet, a Bayesian network-based multimedia knowledge representation framework, is composed by a network of concepts, their relations, and media exemplifying concepts and relationships. The MediaNet integrates classifiers in order to discover statistical relationships among concepts. WordNet is used to process image annotations by stripping out unnecessary information. The summarization process implements a series of strategies to improve the images' description qualities, for example using WordNet and image clusters to disambiguate annotation terms (images in the same clusters tend to have similar textual descriptions). Benitez (2005) also proposes a set of measures to evaluate the knowledge consistency, completeness, and conciseness.

Tansley (2000) used a network at the concept level, and Benitez (2005) used the MediaNet network to capture the relations at both concept and feature levels. In addition, Benitez (2005) utilized

WordNet, which captures human knowledge that is not entirely present in multimedia data.

Summary

The described algorithms vary in many different aspects such as in their low-level features, segmentation methods, feature representation, modeling complexity, or required data. While some concepts require a lot of data to estimate its model (e.g., a car), others are very simple and require just a few examples (e.g., sky). So, we advocate that different approaches should be used for different concept complexities.

Single-class models assume that concepts are independent and that each concept has its own model. These are the simplest models that can be used and the ones with better accuracy (e.g., Yavlinsky et al., 2005).

Translation models, hierarchical models, and network models capture a certain degree of the concept's interdependence (co-occurrence) from the information present in the training data. The difference between the models is linked to the degree of interdependence that can be represented by the model. In practice, when interdependencies information is incorporated in the model, it also inserts noise in the form of false interdependencies, which causes a decrease in performance. So, the theoretical advantage of these models is in practice reduced by this effect.

All these models rely exclusively on visual low-level features in order to capture complex human concepts and to correctly predict new unlabeled data. Most of the time, the training data are limited, and the model's accuracy can be improved by other sources of knowledge. Srikanth et al. (2005) and Benitez (2005) are two of the few proposals that exploit prior knowledge that is external to the training data in order to capture the interdependent (co-occurrence) nature of concepts.

At this time, knowledge-based models seem to be the most promising semantic analysis algorithms for information retrieval. Text information retrieval already has shown great improvement over exclusively statistical models when external linguistic knowledge was used (Harabagiu et al., 2000). Multimedia retrieval will go through a similar progress but at a slower pace, because there is no multimedia ontology that offers the same knowledge base as WordNet offers to linguistic text processing.

SHOT AND SCENE SEMANTIC ANNOTATION

Shot and scene semantic analysis introduces the time dimension to the problem at hand. The time dimension adds temporal frames, resulting in more information to help the analysis. To take advantage of the sequential nature of the data, the natural choices of algorithms are based on hierarchical models or network models. The section is organized by modality, and within each modality, we don't detail the algorithms by technique due to space constraints. This way, we shed some light on multimodality shot and scene semantic analysis and keep the chapter's emphasis on visual information analysis.

Audio Analysis

Audio analysis becomes a very important part of the multimodal analysis task when processing TV news, movies, sport videos, and so forth. Various types of audio can populate the sound track of a multimedia document, the most common types being speech, music, and silence. Lu, Zhang, and Jiang (2002) propose methods to segment audio and to classify each segment as speech, music, silence, and environment sound. A *k*-nearest neighbor model is used at the frame level followed by vector quantization to discriminate between speech and nonspeech. A set of threshold-based rules is used in order to discriminate among silence, music, and environment sound. The authors also describe a speaker change detection algorithm

based on Gaussian-mixture models (GMM); this algorithm continuously compares the model of the present speaker's speech with a model that is created dynamically from the current audio frame. After a speaker change has been detected, the new GMM replaces the current speaker's GMM.

In most TV programs and sport videos, sound events do not overlap, but in narratives (movies and soap operas), these events frequently occur simultaneously. To address this problem, Akutsu, Hamada, and Tonomura (1998) present an audio-based approach to video indexing by detecting speech and music independently, even when they occur simultaneously. Their framework is based on a set of heuristics over features histograms and corresponding thresholds. With a similar goal, Naphade and Huang (2000) define a generic statistical framework based on hidden Markov models (Rabiner, 1989) in order to classify audio segments into speech, silence, music, and miscellaneous and their co-occurrences. By creating an HMM for each class and every combination of classes, the authors achieved a generic framework that is capable of modeling various audio events with high accuracy.

Another important audio analysis task is the classification of the musical genre of a particular audio segment. This can capture the type of emotion that the director wants to communicate (e.g., stress, anxiety, happiness). Tzanetakis and Cook (2002) describe their work on categorizing music as rock, dance, pop, metal, classical, blues, country, hip-hop, reggae, or jazz (jazz and classical music had more subcategories). In addition to the traditional audio features, they also use special features to capture rhythmic characteristics and apply simple statistical models such as GMM and KNN to model each class' feature histogram. Interestingly, the best reported classification precision (61%) is in the same range as human performance for genre classification (70%).

All these approaches work as a single class model of individual classes/keywords. Note that the hidden Markov model is, in fact, a probabilistic network for modeling a single temporal event that corresponds to a given concept/keyword. So, even though it is a network model, it is used as a single class model.

Visual Analysis

Many of the visual video analysis methods are based on heuristics that are deduced empirically. Statistical methods are more common when considering multimodal analysis. Most of the following papers explore the temporal evolution of features to semantically analyze video content (e.g., shot classification, logical units, etc.). Video visual analysis algorithms are of two types: (a) heuristics-based, in which a set of threshold rules decides the content class, and (b) statistical algorithms that are similar to the ones described in Section 2.

Heuristic methods rely on deterministic rules that were defined in some empirical way. These methods monitor histograms, and events are detected if the histogram triggers a given rule (usually a threshold). They are particularly adequate for sport videos because broadcast TV follows a set of video production rules that result in well-defined semantic structures that ease the analysis of the sports videos. Several papers have been published on sports video analysis, such as football, basketball and tennis, in order to detect semantic events and to semantically classify each shot (Li & Sezan, 2003; Luo & Huang, 2003; Tan, Saur, Kulkarni, & Ramadge, 2000).

Tan et al. (2000) introduced a model for estimating camera movements (pan, tilt, and zoom) from the motion vectors of compressed video. The authors further showed how camera motion histograms could be used to discriminate various basketball shots. Prior to this, the video is segmented into shots based on the evolution of the intensity histogram across different frames. Shots are detected if the histogram exceeds a predefined threshold; then, they are discriminated based on (a) the accumulated histogram of cam-

era motion direction (fast breaks and full-court advances), (b) the slope of this histogram (fast breaks or full-court advances), (c) sequence of camera movements (shots at the basket), and (d) persistence of camera motion (close-ups).

Other heuristic methods deploy color histograms, shot duration, and shot sequences to automatically analyze various types of sports such as football (Ekin, Tekalp, & Mehrotra, 2003) and American football (Li & Sezan, 2003).

The statistical approaches reviewed previously can be applied to the visual analysis of video content with the advantage that shapes obtained by segmentation are more accurate due to the time dimension. Also, analyzing several key-frames of the same shot and then combining the results facilitate the identification of semantic entities in a given shot.

Luo and Hwang's (2003) statistical framework tracks objects within a given shot with a dynamic Bayesian network and classifies that shot from a coarse-grain to a fine-grain level. At the course-grain level, a key-frame is extracted from a shot every 0.5 seconds. From these key-frames, motion and global features are extracted, and their temporal evolution is modeled with a hierarchical hidden Markov model (HHMM). Individual HHMMs (a single-class model approach) capture a given semantic shot category. At the fine-grain level analysis, Luo and Hwang (2003) employ object recognition and tracking techniques. After the coarse-grain level analysis, segmentation is performed on the shots to extract visual objects. Then, invariant points are detected in each shape to track the object movement. These points are fed to a dynamic Bayesian network to model detailed events occurring within the shot (e.g., human body movements in a golf game).

Souvannavong, Merialdo, and Huet (2003) used latent semantic analysis to analyze video content. Recall that latent semantic analysis algorithm builds a matrix M of word occurrences in documents, and then the SVD of this matrix is computed to obtain a singular space. The problem with multimedia content is that there is no text corpus (a vocabulary). A vector quantization technique (k-means) returns a codebook of blobs, the vocabulary of blobs from the shots' key-frames. In the singular feature space, a k-nearest-neighbor ($k=20$) and a Gaussian mixture model technique are used to classify new videos. The comparison of the two techniques shows that GMM performs better when there is enough data to correctly estimate the 10 components. The k-nn algorithm has the disadvantages of every nonparametric method—the model is the training data, and for the TRECVID dataset (75,000 key-frames), training can take considerable time.

Multimodal Analysis

In the previous analysis, the audio and visual modalities were considered independently in order to detect semantic entities. These semantic entities are represented in various modalities, capturing different aspects of that same reality. Those modalities contain co-occurring patterns that are synchronized in a given way because they represent the same reality. Thus, synchronization and the strategy to combine the multimodal patterns is the key issue in multimodal analysis. The approaches described in this section explore the multimodality statistics of semantic entities (e.g., pattern synchronization).

Sports video analysis can be greatly improved with multimodal features; for example, the level of excitement expressed by the crowd noise can be a strong indicator of certain events (foul, goal, goal miss, etc). Leonardi, Migliotari, and Prandini (2004) take this into account when designing a multimodal algorithm to detect goals in football videos. A set of visual features from each shot is fed to a Markov chain in order to evaluate their temporal evolution from one shot to the next. The Markov chain has two states that correspond to the goal state and to the nongoal state. The visual analysis returns the positive pair shots, and the shot audio loudness is the criterion to rank the

pair shots. Thus, the two modalities never are combined but are used sequentially. Results show that audio and visual modalities together improve the average precision when compared only to the audio case (Leonardi et al., 2004).

In TV news videos, text is the fundamental modality with the most important information. Westerveld, et al. (2003) build on their previous work described previously to analyze the visual part and to add text provided by an Automatic Speech Recognition (ASR) system. The authors further propose a visual dynamic model to capture the visual temporal characteristics. This model is based on the Gaussian mixture model estimated from the DCT blocks of the frames around each key-frame in the range of 0.5 seconds. In this way, the most significant moving regions are represented by this model with an evident applicability to object tracking. The text retrieval model evaluates a given $Shot_i$ for the queried keywords $Q = q_1, q_2, q_3, ...\}$ (see Box 2).

This measure evaluates the probability that one or more queried keywords appear in the evaluated shot, $p(q_k \mid Shot_i)$, or in the scene, $p(q_k \mid Scene_i)$, under the prior $p(q_k)$. The λ variables correspond to the probabilities of corresponding weights. This function, inspired by language models, creates the scene-shot structure of video content. The visual model and the text model are combined under the assumption that they are independent; thus, the probabilities are simply multiplied. The results with both modalities are reported to be better than using just one.

Naphade and Huang (2001) characterize single-modal concepts (e.g., indoor/outdoor, forest, sky, water) and multimodal concepts (e.g., explosions, rocket launches) with Bayesian networks. The visual part is segmented into shots (Naphade et al., 1998), and from each key-frame, a set of low-level features is extracted (color, texture, blobs, and motion). These features then are used to estimate a Gaussian mixture model of multimedia concepts at region level and then at frame level. The audio part is analyzed with the authors' algorithm described previously (Naphade & Huang, 2000). The outputs of these classifiers are then combined in a Bayesian network in order to improve concept detection. Their experiments show that the Bayesian network improves the detection performance over individual classifiers. IBM's research by Adams et al. (2003) extend the work of Naphade and Huang (2001) by including text from Automatic Speech Recognition as a third modality and by using Support Vector Machines to combine the classifiers' outputs. The comparison of these two combination strategies showed that SVMs (audio, visual, and text) and Bayesian networks (audio and visual) perform equally well. However, since in the latter case, speech information was ignored, one might expect that Bayesian networks can, in fact, perform better. More details about IBM's research work can be found in Naphade and Smith (2003), Natsev, Naphade, and Smith (2003), and Tseng, Lin, Naphade, Natsev, and Smith (2003).

The approach by Snoek and Worring (2005) is unique in the way synchronization and time relations between various patterns are modeled explicitly. They propose a multimedia semantic analysis framework based on Allen's (1983) temporal interval relations. Allen showed that in order to maintain temporal knowledge about any two events, only a small set of relations is needed to represent their temporal relations. These relations, now applied to audio and visual patterns, are the following: precedes, meets, overlaps, starts, dur-

Box 2.

$$RSV\left(Shot_i\right)=\frac{1}{|Q|}\sum_{k=1}^{|Q|}\log\left(\lambda_{Shot}\,p\left(q_k \mid Shot_i\right)+\ _{Scene}\,p\left(q_k \mid Scene_i\right)+\lambda_{Coll}\,p\left(q_k\right)\right)$$

ing, finishes, equals, and no relation. The framework can include context and synchronization of heterogeneous information sources involved in multimodal analysis. Initially, the optimal pattern configuration of temporal relations of a given event is learned from training data by a standard statistical method (maximum entropy, decision trees, and SVMs). New data are classified with the learned model. The authors evaluate the event detection on a soccer video (goal, penalty, yellow card, red card and substitution) and TV news (reporting anchor, monologue, split-view and weather report). The differences among the various classifiers (maximum entropy, decision trees, and SVMs) appear to be not statistically significant.

Summary

When considering video content, a new, very important dimension is added: time. Time adds a lot of redundancy that can be explored effectively in order to achieve a better segmentation and semantic analysis. The most interesting approaches consider time either implicitly (Westerveld et al., 2003) or explicitly (Snoek & Worring, 2005).

Few papers show a deeper level of multimodal combination than Snoek and Worring (2005) and Naphade and Huang (2001). The first explicitly explores the multimodal co-occurrence of patterns resulting from the same event with temporal relations. The latter integrates multimodal patterns in a Bayesian network to explore pattern co-occurrences and concept interdependence.

Natural language processing experts have not yet applied all the techniques from text to the video's extracted speech. Most approaches to extract information from text and combine this with the information extracted from audio and video are all very simple, such as a simple product between the probabilities of various modalities' classifiers.

CONCLUSION

This chapter reviewed semantic-multimedia analysis algorithms with special emphasis on visual content. Multimedia datasets are important research tools that provide a means for researchers to evaluate various information extraction strategies. The two parts are not separate, because algorithm performances are intrinsically related to the dataset on which they are evaluated.

Major developments in semantic-multimedia analysis algorithms will probably be related to knowledge-based models and multimodal fusion algorithms. Future applications might boost knowledge-based model research by enforcing a limited application domain (i.e., a constrained knowledge base). Examples of such applications are football game summaries and mobile photo albums.

Multimodal analysis algorithms already have proven to be crucial in semantic multimedia analysis. Large developments are expected in this young research area due to the several problems that wait to be fully explored and to the TRECVID conference series that is pushing forward this research area through a standard evaluation and a rich multimedia dataset.

We believe that semantic-multimedia information analysis for retrieval applications has delivered its first promises and that many novel contributions will be done over the next years. To better understand the field, the conceptual organization by different statistical methods presented here allows readers to easily put into context novel approaches to be published in the future.

Chapter 4.8
Principles of Educational Software Design

Vassilios Dagdilelis
University of Macedonia, Greece

ABSTRACT

Despite the generalized use of information and communication technologies (ICT) in teaching, their educational applications have not yet been standardized: a general consensus does not exist on how ICT can be applied to teaching nor on how educational software must be constructed. In this chapter, it is argued in favor of educational software construction being guided by a didactic problematique. In this framework we consider as a promising software category mindtools and, in particular, the so-called open microworlds. Their design must be guided by a number of principles: the tool logique, the multiple interface and the multiple representations principles. In this chapter, a detailed critique of these principles is also presented.

INTRODUCTION

From the time computers were invented until today, this latest decade has been intensely characterized, more than any of the previous ones, by the infiltration of the so-called new technologies in everyday life. Information and communication technologies (ICT) are also being integrated into education at all levels. In fact, this integration is a two-way process, as it has consequences for the educational system in which ICT are integrated. The influence of ICT on the way lessons are planned and conducted, on the administration of teaching institutions (schools, universities, and others), on existing teaching methodologies, on evaluation, and finally on the educational system in general, is so deep rooted, that ICT is likely to be the cause of a complete restructuring of the entire educational system.

Despite their use in teaching, which is constantly expanding, as well as the important influence they have on transforming current curricula, the educational applications of ICT have not yet been standardized, meaning that a general consensus does not exist on how ICT can be applied to teaching and a consensus does not exist that can be used as a general guideline for the development of educational software.

More specifically, concerning those points where a consensus of opinion does not exist, the following could be stated:

- **The characteristics of educational software:** There are many categories of educational software, which correspond to the different characteristics of that educational software as well as what its most appropriate use might be. The general characteristics of the software and its use are based on, explicitly or implicitly, learning theories, and pedagogic and didactic assumptions; therefore, these different points of view may be incompatible.
- **The usefulness of computers and educational software:** In certain situations, the effects of ICT on the educational system are obvious. For example, ICT have enabled long-distance learning to be reorganized based on new foundations due to the creation of computing networks and communication mechanisms among users at multiple levels (synchronous or asynchronous, with images, sound, video).
  In the majority of cases, even though the use of ICT is considered imperative, because, theoretically at least, ICT improve the lesson, this improvement, however, has not been amply documented. In other words, even though a basic reason for the use of ICT in education is the hypothesis that they improve both teaching and learning, the conditions that render teaching more effective are not actually known, and often, related research does not highlight any significant difference in the quality of the lessons based on ICT (http://teleeducation.nb.ca/nosignificantdifference/). Opinions have also been expressed which indirectly question the overall usefulness of ICT as a means of teaching support (Cuban, 2001; Stoll, 2000).
- **The validity and theoretical support of experimental data:** All over the world, experimental teaching methods and research studies are being carried out in order to discern the particular uses that will be most effective from a teaching perspective. One part of the research, as well as one section of the international literature related to the pedagogic uses of ICT, is geared at describing the characteristics of successful educational software. Unfortunately, research on teaching in the last few years, even though numerous, is not usually accompanied by a satisfactory theoretical background and thus has not managed to come up with substantial data to enable the design of adequate educational software and organize effective didactic situations.
- **The absence of a method for the construction of educational software:** Nowadays, two major categories appear to exist in the way educational software is constructed, each of which comprises several subcategories. In the first, the focus is on technology, meaning the technical features of the software and its construction method. In the second, the starting point is the teaching/learning process the software will support.

In this chapter, it is argued in favor of educational software construction being guided by a *didactic problématique*. Further, educational software must be created according to the most up-to-date learning theories and, more specifically, constructivism.

In this framework, the most promising software category is *mindtools* and, in particular, the so-called *open microworlds.*

The research to date, in conjunction with the large number of available educational software and, in general, digitalized educational material, have contributed to the relative progress that has taken place, but only in certain fields. Thus, concerning these mindtools, we have at our disposal a know-how that allows us to design, but only in certain situations, educational software and more general educational environments with notable functional features. This know-how can be sum-

marized in the form of general design principles on which an educational environment can be based (or at least some sections of it).

These principles are the following:

- The principle of *tool logic*: Computers and ICT in general, should be used as tools in order to make learning easier.
- The principle of multiple interface: The interface should offer the users the ability to express themselves not only by direct manipulation of objects but also with an active formulation of commands and instructions.
- The principle of multiple representations: Knowledge within the context of educational environments should be expressed in many ways, through multiple frameworks that are interconnected and equivalent from a functional point of view.

In the following paragraphs, a detailed critique of these principles is also presented.

EDUCATIONAL SOFTWARE DEVELOPMENT METHODS

Educational software was an area in which a medium level of production existed 20 years ago, however, in the last decade, in which time the graphical user interface (GUI) was established, production has become intense. Educational software originated mainly from two different sources, which in many cases cooperated: one source was software-producing companies and the other was the academic institutions, such as university laboratories or research centers and institutes (Harvey, 1995; van der Mast, 1995). This dual source essentially corresponds to the fact that in the last decade there has been significant progress, both in the level of technological know-how as well as in teaching theory, because current teaching know-how, despite the serious drawbacks pointed out in the introduction, has greatly improved in comparison to 20 years ago.

As was natural, the large amount of production gradually led to the development of various models of educational software, which can be used as guidelines in the creation of new educational software; a creation which, very likely may, in turn, lead to the improvement or even to a radical revision of existing models. Needless to say, this cycle can continue for a long period of time.

In the international literature, numerous models on the construction of educational software have been proposed, such as that described by Lage et al. (2002). This representative model proposes the use of "an incremental prototype life cycle" of 11 stages along general lines that must be followed for the construction of educational software. It is obvious that this model has been influenced by the general methodology of software engineering and attempts to adapt its general characteristics to educational software.

This type of methodology, as well as others like it, even though they might be considered effective from the point of view of developing software, is independent of both its *content* and its *didactic use*. This model, which is structured according to the principles of software engineering, does not actually focus on the most important aspect of educational software, namely, its teaching characteristics. Therefore, the models in this category are useful in describing the process for the development of educational software but have little value as tools for analyzing how useful particular educational software is for teaching purposes.

Another method used generally in the design of educational means and environments (Instructional Design) can also be used, such as the model ADDIE (Analysis, Design, Development, Implementation, Evaluation). This category is usually referred to as *tutorial* software.

One final category we often come across is that which proposes lists of practical advice or checklists covering certain aspects of educational

software (Beale & Sharples, 2002), with the drawback that it does not present a comprehensive set of principles on which this type of environment can be constructed.

The development of models or methods for the construction and use of educational software is, as a rule, either oriented toward the rationale of software engineering, or, consequently lacking in teaching parity, refers to the teaching characteristics of the software and is thus often fragmentary.

It is obvious that the construction of educational software should be based on some method, otherwise it is in danger of failing, of costing too much, or of being greatly delayed. This method, however, should be subject to the didactic rationale and not the other way round (Reusser, 1994). The basic characteristic of educational software should be its didactic efficiency rather than its technological supremacy, even though this, of course, is also desired.

KNOWLEDGE THEORIES AND DIDACTIC PROBLÉMATIQUE

Behaviorism and Constructivism

The many types of contemporary educational environments are certainly well-known: from the simplest drill-and-practice-type software to the more complex educational microworlds, a gamut of educational applications exists with a wide range of technical features, the interface, the audience they are geared to, and the goals aimed at. The wealth of environments is enormous, and their categorizations can be based on numerous criteria. It is generally accepted that the design of educational environments, whether digital or not, is guided, even at a subconscious level, by the pedagogic theories of the manufacturers. The choice of a theory is so important that most times it determines, directly or indirectly, the characteristics of the educational environment or even its type. Therefore, a large section of the educational applications with essential aims to convey knowledge and skills, many e-books for instance, belong to the behaviorist school (Collins, 1996).

Behaviorism and constructivism are two widely spread learning theories that are fundamentally different in their outlooks.

Behaviorism, which appears at an international level to be waning, assumes that learning is the result of a stimulus–response process. Learning is seen largely to be a passive procedure, where the subject attempts to adapt to the environment.

The constructivist approach, at polar ends with the behaviorist, is based on the hypothesis that subjects construct their own, personal knowledge through interaction with the environment; while learning essentially consists of a teaching methodology based on assimilating new information and then adapting the subject's mental structures in such a way as to be compatible with the new data. In the constructivist learning model, the subject, in attempting to explain or to examine questions, formulates hypotheses; searches for ways to verify or disprove these hypotheses; interacts with his or her environment (both material and human); redirects the results of experiences; and constantly reconstructs intellectual structures, the mental shapes, in such a way as to integrate them with the new data. Therefore, the educational environments of the constructivist paradigm differ greatly from those based on the behaviorism, because they favor active learning, cooperation between learners, investigation, formulation of hypotheses, as well as their verification or disproof. In other words, they promote actions and activities similar to scientific work, even though in reality, scientists' work is fundamentally different than that of students' work.

The Constructivist Approach

To a large extent, the various categories of educational software correspond to those of learning

theories, which they are based on. For this reason, there is no general consensus on educational software. On the contrary, these various categories coexist. As is natural within the framework of the various schools of thought, extended argumentation has been put forward from all sides.

The main argument for the preference of the constructivist approach and, subsequently, for cognitive tools, can be expressed by borrowing the characteristic metaphor of Resnick et al. (1996), who, arguing in favor of the "constructivist" environments, claim that all parents would prefer their children to learn to play the piano rather than learn to use a stereo. Even though it is much easier to use a stereo, the experience offered in learning to play a musical instrument as well as the likelihood of composing musical scores is incomparably richer than merely using even the most advanced electronic device.

Of course, the counterargument to this is that if someone wants to listen to high-quality music, 99 times out of 100, they will use a stereophonic system rather than attempt the arduous task of learning to play the piano. Moreover, it is almost certain that even those people who know how to play the piano own some kind of stereophonic system.

Nevertheless, a basic part of the authors' reasoning remains indisputable: the richest experiences are not gained by the simplest means, perhaps the opposite occurs—experiences are usually analogous to *the power of expression* the means offers the user. In this way, learning the piano decisively contributes to the creation and development of a relationship between the person and music that is rich in feelings. It must be admitted, however, that sometimes this relationship requires the use of devices that reproduce rather than produce sound, that is, the stereo, not the piano.

What then, if any, is the conclusion? We could say that the choice of the *means* is determined by the type of *use* one requires. This is also the case for educational software—its characteristics depend on the use for which it was made.

Mindtools

Throughout human history, technology has obviously contributed to the development of the human intellect and especially to that of learning. Pea (1985) defined *cognitive technology* as "any medium that helps transcend the limits of the mind, such as memory, in activities of thinking, learning and problem solving." Within this more general framework, certain computing environments, more precisely the environments and their didactic use, are usually characterized as *cognitive tools* (Collins, 2000) or even as *mindtools* (Jonassen, 2000), i.e., "computer-based tools and learning environments that have been adapted or developed a function as intellectual partners with the learner in order to engage and facilitate critical thinking and higher order learning" (p. 9). This category of educational environments presents certain significant didactic features.

There are numerous definitions and a relatively adequate amount of literature on cognitive tools or mindtools. According to Jonassen, Peck, and Wilson (1999), an educational environment should support knowledge construction, explorations, learning by doing, learning by conversing, intellectual partners that support learning by reflecting. On the basis of this analysis, therefore, it is possible to evaluate the various sections and functions of educational software, or more precisely, of an educational environment. Those sections and functions that serve or support the above-mentioned uses are thus more desirable. For example, the existence of a system of written communication between learners is a desirable characteristic if it is a prerequisite for the creation of communication and subsequently a type of social interaction between learners; this, however, is a characteristic of particular significance in the development of knowledge on the subject according to current didactic theories (Laborde, 1983). It should be emphasized that this criterion is too broad and, as a consequence, has only limited usability.

The choice of a specific group of software and the knowledge theory supporting it, unavoidably creates a generalization of design principles or, more precisely, a generalized criterion: if the end result is the creation of an educational software, of an educational environment intended to function as a cognitive tool, then its various sections and their functions must also be in accordance with this same rationale.

OPEN ENVIRONMENTS AND OPEN MICROWORLDS

Cognitive tools are not defined in any one way, and there are many types of software that fall into this category. The principles of their design have a general character, and although they cannot be applied to all types of educational environments, they are nevertheless useful as guides in the design of many such environments.

Cognitive tools, by their nature, are *open environments*. Those environments that do not have predetermined lessons or activities that the learner must follow but allow for the free development of activities within the framework of an area of knowledge can be considered as open environments.

There are many types of such environments, from Logo to the current ones such as the environments of so-called Dynamic Geometry (Bellemain, 1992) and others that are based on the synthesis of preexisting components (Rochelle et al., 1999). They have a number of characteristics in common that characterize them as mindtools and that have been "well-established" and, up to a point, have a theoretical basis.

Despite the fact that in recent years, open environments have been recognized as valuable learning environments, certain reservations have also been stated. Collins (2000) asked whether the environment should encourage guided learning or exploratory learning, and highlighted the fact that open environments actually allow the learner to "play around" with the software. He, himself, however, argued in favor of environments which in the beginning are rather guided until the learners gain a certain level of skill in order to be able to use them on their own and who gradually will be liberated. In reality, however, all educational software functions within the particular context of a *teaching situation*. As a rule, learners are required to solve a problem or to explore the various angles of a problem. So, it is unlikely that they "play around" (Hoyles & Noss, 1993).

A special category of software with a large teaching potential includes the so-called *open microworlds*, that is, the environments in which predetermined activities and lessons do not exist, but where learners can define new objects (programs, geometric shapes, functions, natural laws) as well as the relationships between them, in order to experiment (Hoyles & Noss, 1993; Bellemain, 1992; Tinker, 1993).

The developments of open environments, which favor experimental learning and problem solving, have proliferated in recent years. In these environments, a specified teaching scenario or route does not exist; the teaching material that accompanies these environments simply indicates the type of didactic situation.

The potential of these environments is of particular importance to teaching: the ability to choose to decrease the teaching noise (that is, undesirable side effects such as extremely long calculations that can totally overshadow the real objective of the lesson), the intelligent help (in conjunction with intelligent messages), and the programming by demonstration (Bellemain, 1992; Cypher, 1994).

Furthermore, these environments allow learners to express their ideas, even if erroneous, and apply them until they come to a dead-end or to an obviously wrong conclusion (Dagdilelis et al., 2003). If we accept the basic principles of constructivism (Balacheff, 1986; translation from French), these are necessary conditions in order "to provoke a knowledge confrontation and thus

develop learners' perceptions." Resnick et al. (1996) considered data that make the environment familiar to also be important. This familiarity does not aim at giving the learner motives but rather is necessary in order for the learner to be able to use a representational model in order to find the solution to the proposed problem. Such tools enable learners to represent their thought processes in external models for examination and reflection, and may further help them to improve these processes (Emrah, 1995).

The general principles described below are related to open environments designed with the rationale characteristic of the bulk of mindtools.

The Principle of *Tool Logic*

By nature, cognitive tools consist of environments in which the learner can explore phenomena from various angles and, by experimenting with these, reach certain conclusions. They are connected, either directly or indirectly, with possibly more than one field of knowledge (for example, working with Excel on a certain kind of problem requires a combination of programming and mathematics). They often provide the learner with the representation of a microworld, either natural or intellectual, and at the same time a series of tools needed for its exploration. For example, the so-called Dynamic Geometry environments [such as Cabri-Geometer (Bellemain, 1992) or Geometer Sketchpad (Roschelle & Jackiw, 2000)] consist of a simulation of Euclidian space (a totally mental construction that does not exist in reality), whereas the environments for the study of natural phenomena (such as Interactive Physics, 2003) represent natural space in which Newton's laws hold.

An important issue that arises is one concerning the dichotomy between an environment of "physical and epistemological faithfulness" (Collins, 2000). A true natural representation means that the educational environment depicts the actual situation, whereas an epistemological one means that in the educational environment, the same laws (mathematical, natural, etc.) apply, which also exist in nature. The most appropriate choice for either one or the other situation, or to be more precise, the necessity for natural faithfulness, because the other option is regarded as imperative, depends on the use the software is geared for. For example, the study of space from a geometric perspective might demand its simulation in order for the learner to be able to relate to and solve geometric problems under "real" conditions, such as measuring the distances of two points, which between them are not visible, or measuring the area of a golf course, which has an odd shape with a small lake in the middle. On the other hand, where the object of study might be the so-called theoretical (Euclidian) geometry, in which case the environment must "simulate" Euclidian space that, as stated above, does not actually exist because it is simply an intellectual construction, scientific faithfulness is adequate and sufficient.

The existence of natural faithfulness is a significant factor in the learning of concepts and relationships on account that it contains elements familiar to the learner. Furthermore, the existence of natural faithfulness makes it easier to apply the principle of *authenticity*, in other words, the teaching requirement for contextualized learning in an environment that is as close as possible to reality (Collins, 2000). Even though this principle has validity, the main object of research in a cognitive tool is not so much natural faithfulness as epistemological faithfulness, that is, the agreement of the environment and the reactions with the simulated system (Resnick et al., 1996).

Epistemological or physical faithfulness is not, however, a sufficient condition to justify the use of ICT. For example, an environment in which simply the construction of geometric shapes is possible does not make it a cognitive tool. The criterion is the principle of tool logic and its *didactic economy.* An educational environment contains a particular tool that supports a teaching method or the learn-

ing of certain concepts, and it should be designed as such. In addition, however, the potential of the teaching environment should be higher than that of usual environments. For example, software for physics should offer greater possibilities than that available in an actual laboratory. In other words, the design of an educational environment should be based on specific teaching needs, which are revealed by research on teaching or from the experience of teachers, rather than the other way around. This, of course, does not mean that the educational environment cannot break into new possibilities, but rather that in some way, the educational software should comprise the best possible means for the teaching of a concept or a technique.

Tool logic can, of course, vary as to its exact content from one area of knowledge to another and from one software program to another. Nevertheless, certain characteristics of educational environments, considered as cognitive tools for the learner, seem to play important roles in the learning process:

1. The environment should combine conviviality and usability. This means that the educational software should be simple and easy-to-use. An environment that requires complex procedures often forces the learner to focus on technical details instead of concentrate on the problem at hand. Novice programmers, for instance, often focus on dealing with the syntactic errors instead of with the construction of the algorithm—this is precisely the kind of *teaching noise* mentioned above. This fact has led to the creation of simpler languages in order to introduce learners to programming. A practical measure of usability is the effort and time needed to accomplish a task. More generally, the key criterion of a system's usability is the extent to which it enables people who use it to understand it, to learn and to make changes (Nielsen & Mack, 1994).
2. The possibility of avoiding *teaching noise* focuses on the essence (Tall, 1993). Teaching noise does not only come from a nonoptimal interface, as was the case in the above paragraph, but also from the use of methods and procedures that are inappropriate for the user. An essential function of educational environments is that in solving a problem, the user does not get caught up in any time-consuming processes that are counterproductive to learning. For example, a software such as Excel executes complex calculations with high precision and thus avoids teaching noise. This means that any in-between procedures that might take a lot of time and do not benefit learning are done away with. Usually, teaching noise can initially be an *object of learning*, which evolves into a means; and teaching economy often imposes its marginalization in the process of problem solving (Douady, 1993). For instance, basic calculations are an object of learning in the first years of schooling, which however, become the means to solving complex problems in physics and mathematics in the 11^{th} or 12^{th} year of school. Now, if a software allows the problems to be completed quickly, then this releases the learner from a tedious process that has no learning benefit (only the execution of many basic calculations). For this reason, in many software programs, the available information or representations can be increased or reduced, depending on the needs of the lesson (Bellemain, 1992; Dagdilelis et al., 2003).
3. The environment's large potential for expression is revealed in stages through the possibility of creating composite structures, with more specific and stronger tools. The procedures in Logo, the macroconstructions in the environments of dynamic geometry, and the formulae in Excel and the other spreadsheets, are examples of this type, because they offer the user the possibility to

compose new objects of the corresponding space (construction processes, geometric shapes, and algebraic relationships, respectively) based on the software's relatively simple primitives.

4. The possibilities to adapt to the user's needs and provide teaching help are given. This is perhaps the most difficult prerequisite from a technical point of view, because adapting to the needs of the user is materialized at multiple levels. For example, a module of the system can offer intelligent guidance in the use of the software. But, adaptation can be extended to more interesting teaching fields. For instance, in a contemporary educational environment, recordability, that is, the ability to continuously record the user's actions, is now a common option that presents interesting possibilities (Bellemain, 1992). Besides the obvious use of these records by the teacher, who, at times, with the help of the software itself, can analyze the learners' actions and gain valuable insights and results, the system can diagnose certain characteristics of the learners and offer them the necessary help by showing them the weaknesses in their solutions or even help them solve the problem in a variety of ways. In certain environments (such as Cabri-Geometer; Bellemain, 1992) of this type, the software can decide on, for the accuracy or not of a question the learner is formulating (e.g., are these points on the same straight line?), whether to point out the possible weaknesses of a program or to propose improvements or even correct solutions reached by the learner.
5. The possibility of communication is provided. Contemporary constructivist theories believe that humans do not learn in isolation but construct their knowledge through interacting with their environment, which consists of other people, including co-learners and teachers. The progress of network technology in the last decade has created the preconditions for the development of communication systems, even between learners and teachers who are geographically separated. However, it must be emphasized that, despite all its progress, technology is not yet adequately functional, and despite the theories that support the value of communication, we have but a few satisfactory examples of use that surpass the level of being commonplace.

Within tool logic, teaching economy imposes the integration into the environment of those elements that have a meaning from a teaching point of view. Therefore, the parts that characterize the environment, such as the multimedia elements, should serve some teaching goal and should not exist merely for effect.

The most important consequence of the principle of tool logic, however, is the need for educational software to be incorporated *into teaching.* This fact means that it is essential for educational software to be accompanied by a description of the corresponding didactic situations, within the framework in which the application will be used. This is necessary because even the best software is meaningless if it does not function within the context of a didactic situation (Brousseau, 1986a, 1986b). On the other hand, software exists that, although not educational, can be used as a cognitive tool within teaching, such as Excel and spreadsheets generally, as well as mathematics software such as Mathematica and the like.

The opposite phenomenon can, of course, be assumed, of the use of extremely rich software in an elementary way, especially in the situation where a corresponding didactic problématique does not exist.

ROLE OF THE INTERFACE AND THE PRINCIPLE OF MULTIPLE INTERFACE

The interface of contemporary educational environments plays an incredibly significant role in the process of learning, because it essentially determines the way in which learners will formulate their ideas. In this way, the interface indirectly determines an environment's expressive power (Climaco et al., 1993). The expressive power of an environment indicates how quickly and simply the tools enable a description of situations the users can immediately perceive in terms of existing goals and needs. It stands to reason that the environment should support a means of expression that will be simple but at the same time have the ability to formulate complex concepts. These two requirements can, however, be antithetical. In reality, there are at least two different systems that serve them.

Modern interface is characterized by the existence of graphics (GUI). In these new graphic environments the specific elements are the "*image-action*" and the *objectification* metaphor: actions are substituted by the duo *icons* and *actions with the mouse* (for example, clicking on the icon of a diskette has the result of saving the active file). This progress of the interface, in turn, leads to the development of a very interesting ability, that of direct manipulation (Bellemain & Dagdilelis, 1993). With direct manipulation, the user can "handle" objects (their representations) on the monitor, using a mouse directly on the image of the "object." An obvious characteristic of direct manipulation is, of course, that it does not require any kind of formulation on the part of the user. In order to destroy a file, all that is needed is to "throw it away" and to "empty" the "recycling bin." This, however, does not necessarily mean that the nonexplicitly expressed commands in every environment are direct use: in the *e-examples* of NCTM (National Council of Teachers of Mathematics), for instance, there is also a tiny programming environment for primary school children that does not require any written formulation—they use an iconic language—while in the past, there were other software with similar characteristics. In modern graphic environments, concepts and their relationships acquire a pseudomaterial basis, they appear to be—and behave as though they are—materials; for example, in the environments of Dynamic Geometry, the straight-line sections act as though they were elastic (they can elongate or shrink simply by dragging and dropping their ends), and in certain environments of Dynamic Algebra, the graphic representations function as though they are wire (they too permit modifications such as parallel transformation or flexure simply by drag and drop; Function Probe, 1999).

Direct manipulation, in this way, acquires particular importance as a teaching possibility, because it allows the user to express, in a direct way, relationships and choices that, in everyday terms, are unclear, because usually the user can *act* on them but not *express* them. In this way, direct manipulation gives the ability to choose a shade of color from a palette, the free-hand design of a shape, or the construction of a digital object, activities that are possibly familiar to the user but cannot easily be described (Eisenberg, 1996). Moreover, the conflict between "I do" and "I explain how to do" (Duchateau, 1992), is well-known as one of the common difficulties of novice programmers. For example, novice programmers can easily understand the design rule of a recursive shape, such as embedded squares or Koch's snowflakes, but they come up against great difficulty when they attempt to construct a recursive procedure that designs them (Carlisle, 2000; Dalit, 2001).

The advantage that direct manipulation has on teaching is particularly obvious in the cases where it is an essential *teaching variable*, that is, a factor that can greatly affect the teaching and learning processes by being present or absent. Early educational software for geometry, for in-

stance, which were mainly based on the explicit formulation of commands (such as GEOMLAND; Sendov & Sendova, 1995), turned out to be more difficult to use by young learners. In certain cases, the use of the "objects" or at least certain elements of the system is carried out through intermediate iconic mechanisms, such as sliders, of which Microworlds Pro and Avakeeo are well-known examples (Microworlds Pro, 1999; Koutlis & Hatzilacos, 1999). Nowadays, technology even allows for commands to be given indirectly to computers by demonstration (Bellemain, 1992; Cypher, 1994).

Direct manipulation comprises one end of the scale, while on the other end are the explicit formulation environments (such as Logo). Nevertheless, the inexplicit manipulation of objects is not the only solution and can coexist with the explicit expression of commands. International research shows (di Sessa et al., 1995; Hoyles, 1995; Sendov & Sendova, 1995; Laborde & Laborde, 1995) that direct manipulation is neither the only means nor the most appropriate solution for all situations. If direct manipulation offers ease in expression, explicit formulation offers the possibility to express composite concepts and relationships. Written formulation offers a large expression potential to the user, who can describe sophisticated relationships such as recursion or patterns with much greater ease than with either direct or indirect manipulation. In reality, the formulation of definitions, properties, and relationships is a component of the concepts themselves; it requires specialized knowledge that should be cultivated in the learner (Laborde, 1983).

The majority of typical languages, which enables a high degree of structure, are usually programming languages of some sort. Programming languages, of course, have their own teaching value but are, in some way, incredibly decontextualized, which means that they function in abstract and, thus, are often difficult to learn. On the contrary, in recent years, a generation of specific languages has appeared that has been adapted to the particularity of the environments in which they function. Thus, languages are being developed that allow the formulation of geometric or other causal dependencies (Sketchpad, 2003). In fact, the existence of these languages can make the software much more functional, because up to now, the tendency has been for software development to constantly add new features and tools, resulting in the creation of environments with scores of abilities but with problematic in-depth use (Eisenberg, 1996). It is worth noting that this problem as well as its suggested solution were highlighted 30 years ago in the area of programming. Dijkstra (1972) characterized certain languages as "baroque monstrosities" and argued in favor of languages with a small repertory of commands but that had a high possibility of composing new ones.

Particular teaching problems, such as the choice of functional syntax and the appropriate formalism arise due to the existence of specific descriptive languages. However, with the use of various techniques, these problems can nowadays be dealt with to a satisfactory degree.

So, as current research shows, each of the methods of expression (manipulation or formulation) has its advantages and disadvantages; therefore, the best construction strategy for educational environments is to incorporate both methods that have the capacity to be used for contemporary needs. Perhaps the best examples are computers and their operating systems. The two most popular systems (Windows and Unix in various forms) coexist, serving different groups of users and converging to become a "double" nature, as it were—Windows has written commands, while for the Unix-like systems, X-Windows have now become an important component.

MULTIPLE REPRESENTATIONS

The progress of technology (high-analysis monitors, fast processors and graphic cards, effective

algorithms, etc.) has enabled, to a great extent, the development of technical illustrations with animated or unanimated images or video. Current educational environments are using these new means all the more extensively: animated images that are also interactive. The particularly significant role of images has often been emphasized in the international literature (Tall, 1993; Kaylan, 1993).

The progress of technology has also increased the potential of another section of educational environments, namely, that of *multiple representations*. A representation, in this case, is a system that symbolizes certain knowledge. For example, a mathematical function can be represented as a formula or as a graph; an algorithm can be represented in the form of diagrams or in a textual programming language.

Support multiple representational forms enable the learner to represent concepts and meaningful relationships between concepts both verbally and pictorially (Kozma, 1992) and allow the learner access to the different representations simultaneously, so that interrelationships are directly available (Emrah, 1995).

Multiple representations are not necessarily totally based on pictures. According to Beale et al. (2002), they include interactive systems of "external representations. External representations are observable, and often manipulatable, structures, such as graphs, tables, diagrams or sketches that can aid problem solving or learning" (p. 18). Here, external representations are regarded in the broad sense of the term, including in them *textual representations*, in other words, subordinate texts. The importance of external representations is that each one can comprise a significant teaching aid for the learner, because it contains important information. For example, these types of representations can make obvious the relationship between data-producing sets with common characteristics, tendencies, or properties. Of course, these representations have the disadvantage that, although they make certain properties of the concepts under study obvious, they leave out certain others. Often, one type of external representation is particularly useful in order to solve a certain category of problems but is inappropriate for all the others. This drawback is overcome by the existence of multiple external representations.

Of particular interest are those external representations that are dynamic and interconnected and in fact bidirectional. In other words, they present *symmetrical possibility*. In educational environments, one form of expressing a concept or relationship is often preferred over another, due to the particular *didactic contract* (Brousseau, 1986) that commonly exists in school environments or simply due to technical reasons. Thus, a graphic representation of a function can often result from its analytical expression, and the change to the analytical expression causes a modification of the curve but not the opposite. This modification has been previously pointed out (Bellemain & Dagdilelis, 1993; Schwarz, 1993) and integrated into earlier pilot software or more recently, into well-known software (such as Function Probe, 1999). However, this possibility is limited, as it can be used only for certain categories of functions that are known beforehand. At school, most explored functions are known beforehand, so this is not a concern.

Recent research studies on teaching in various scientific fields have shown (Douady, 1993; Tall, 1993) that *multiple representations* clearly have teaching value. For example, the representation of a mathematical function in an analytical, graphical, and numerical way with the ability of direct interaction between the various frameworks of expression allows the learner to produce more complete images of the concept being examined and to develop significant notions on it, even when lacking basic knowledge (Tall, 1993). Environments should offer the option of choice between one or multiple representations, depending on the teaching needs at the time. In this way, for instance, multiple representations for computing

programs executed simultaneously on DELYS (Dagdilelis et al., 2003)—a software developed by the University of Macedonia (Thessaloniki, Greece) for the teaching of programming—the user can decide which functions will be visible and which will not.

SYNTHESIS

In the above paragraphs, three basic principles for the design of modern educational environments were presented: the principle of tool logic, the principle of multiple interfaces, and the principle of multiple representations. Although the number of such principles has not been exhausted, as the research data show, they contribute significantly to the development of educational environments with high didactic specifications.

The rationale behind the examination of these design principles was focused on their teaching functions rather than on the logic of software engineering. This is the reason why general principles related to those categories of educational software that appear to be the most promising, that is, cognitive tools, were chosen. The main conclusion from the study of these educational environments is that a basic factor for their effective use in teaching is the *didactic situation in which they are applied*. The value of cognitive tools lies precisely in their ability to support situations with a rich teaching potential. With few exceptions, research on teaching does not seem to have progressed at the same rate as that on the technology of educational software. This fact explains the general impression, which exists internationally, that educational software has not yet succeeded in achieving its goal to improve teaching to the level expected. This is a direction that should be followed in order to succeed in the design and construction of even better quality educational environments and also simultaneously to make better use of existing software.

Chapter 4.9
Online Multimedia Educational Application for Teaching Multimedia Contents:
An Experiment with Students in Higher Education

Alcina Prata
Higher School of Management Sciences (ESCE), Portugal

Pedro Faria Lopes
Higher Institute of Labour and Business Studies (ISCTE), Portugal

ABSTRACT

This chapter describes an experiment undertaken with higher education level students, which consists of utilizing an online multimedia educational application as an aid in teaching organizational multimedia. This course is taught to fourth year students at the Escola Superior de Ciências Empresariais (Higher School of Management Sciences, Setúbal, Portugal), where the first author teaches. This chapter also describes the educational software model used for the planning, development and evaluation of the above-mentioned application. This model is the result of the integration of the model presented in the first author's Master's thesis with methods, methodologies and guidelines proposed by others. As for the resulting application, the manner in which it was applied and its evaluation are also presented in this document. The results obtained are then interpreted and future developments proposed.

INTRODUCTION

The use of information technology currently plays an important part in the day-to-day of the majority of public and private institutions. The traditional educational system also has had to adapt to this new way of doing things (Chambel et al., 1998) and has benefited significantly from the contribution of these types of technological applications (Azevedo, 1997; Hartley, 1999; McCarthy, 1995). Likewise, the reigning "professional philosophy"

has also evolved towards the notion of life-long learning (Ryan et al., 2000). Professional careers are becoming increasingly demanding, implying a rapid adaptation to new circumstances and constant acceleration in education, preferably without dismissing employees (Abbey, 2000; Chute et al., 1999). All this leads us to e-learning: a teaching method which utilizes Internet technologies to supply, at a distance, a range of solutions for the acquisition and/or updating of knowledge (Machado, 2001; Rosenberg, 2001; Ryan et al., 2000).

The main reason for the growing popularity of this teaching method is the fact that it combines the advantages of using information technology in education (Azevedo, 1997) with the advantages of distance learning (Machado, 2001; Rosenberg, 2001), namely, access to information using the new instructional model "anytime, anyplace and anybody" (Aggarwal, 2000). This was, therefore, the main reason for choosing to develop and use an Online Multimedia Educational Application (OMEA) to serve as an aid in the teaching of *Organizational Multimedia*, a course taken by fourth year students at the Higher School of Management Sciences. As this is a compulsory course, the classes tended to be very heterogeneous, bringing together students from five different academic areas. Given that the students had different schedules and study constraints, this naturally implied a few difficulties when teaching the course. So, with OMEA, the main goal was to solve this problem, and render access to information easier for anybody, anytime and anyplace. At the same time, we were expecting to benefit from the advantages of using information technology (namely Web-based technology) as a teaching support inside and outside classroom and, finally, to contribute to the modernization of study methods used by students. Other goals were to acquire more experience in planning, developing and evaluating online educational applications and to research the critical process of developing real educational, multimedia and interactive online applications. Unfortunately, in spite of all the advantages associated with the use of information technology (namely Web-based technology) as teaching support, we still have a long way to go in the planning and development of real educational, multimedia and interactive online applications. As a recent and supposedly lucrative phenomenon, e-learning is now concentrating all the efforts of the majority of teaching institutions (Palloff et al., 2001). However, this effort is mainly concentrated on the search for the "ideal" platform, instead of the "ideal" content. So, it is usual to find technologically strong platforms supporting very poor content. In a study to evaluate the online educational applications delivered by some university e-learning platforms (Prata et al., 2003a), we saw that the majority:

- Are not interactive
- Are mainly text-based
- Are not planned and developed by following adequate educational software models and educational and pedagogical rules
- Are made available, at least initially, without being properly tested, namely by getting some feedback from the target population

In the development process of the OMEA, which was supposed to serve as an aid in the teaching of the *Organizational Multimedia* course, we tried to overcome the problems mentioned above, namely by creating an online application:

- That could act as a substitute for the face to face classes that the students could not attend
- That would allow the students to achieve the same results they would achieve by attending the face to face classes
- That would correspond to the target population's expectations and needs
- That would be motivating
- As well as interactive
- And pedagogically adequate

- Which would include different types of media components, namely, text, image, graphics, sound, animation and video
- Which would follow an adequate educational software model for its planning, development and evaluation
- That would be appropriately tested
- That could be integrated as an help/support tool in the classroom
- That could be used by the students as a regular tool/support to their study
- That could be available on the Web on a short-term basis, and later easily adapted to the school-specific intranet and e-learning platforms
- That could be adapted to any standardized e-learning platform (LMS)

In the following sections of this chapter we will justify in more detail the need for this kind of study and its contribution to the resulting OMEA. We will also explain the characteristics of the OMEA developed, present the educational software model used for the planning, development and evaluation of this OMEA and explain the evaluation method used to assess it. Finally, the results obtained will be presented and interpreted, and future developments will be proposed.

BACKGROUND

In recent years information technology has become more commonplace in many areas partly due to government initiatives such as society digitalization, and due to the general public's growing awareness of the Internet as a privileged vehicle for obtaining information. The utilization of these technologies (online and off-line multimedia contents) is presently part of the day-to-day of the vast majority of public and private institutions. Traditional education systems also felt the need to adapt to this new society (Chambel et al., 1998) and have benefited significantly from the contributions of these types of contents (Azevedo, 1997; Hartley, 1999; McCarthy, 1995). Some studies made in order to evaluate the impact, in general terms, of using computers and multimedia in teaching, demonstrate that these types of environments promote creative rationalization, problem solving approaches, strategy formulation, and persistence in the pursuit of goals. Since they promote the use of different sensorial channels, they also represent substantial gains in terms of learning, retention and understanding of issues (Azevedo, 1997; McCarthy, 1995). In other words, they are a more stimulating and involving study method than traditional materials since they imply increased adaptability to different styles of learning, greater involvement of students in the learning process and, also, offer equal advantages for students with or without previous knowledge of information technology. In short, computers and multimedia are a consistent teaching method and, on a worldwide scale, a new learning model (Könyves-Tóth et al., 1995).

Another issue widely discussed nowadays, although not a recent phenomenon, is Long Distance Learning (LDL), which is characterized as an educational event where learning is undertaken by a physical separation (geographical and/or temporal) between students and teachers (Santos, 2000). LDL has emerged as a way of bringing flexibility to educational resources and of leaving less mobile populations the option of continuing their studies/further education. Increasingly, with time, that less mobile population has grown. The "professional philosophy" has also evolved towards a notion of life-long learning (Ryan et al., 2000), and professional careers in most institutions are becoming increasingly demanding, requiring rapid adaptation to new circumstances and constant education, preferably without employee absence to achieve these objectives (Abbey, 2000; Chute et al., 1999). LDL has become the only alternative for many. This teaching method has also evolved with time. What first started as an educational project by means of the post, or tele-school in the

1960s (classes broadcast over the traditional TV network) and CD-ROM based media in the 90s, is now often based on e-learning systems (which have been continuously refined since the Internet's appearance about 10 years ago) (Machado, 2001). E-learning can be defined as a teaching method which utilizes Internet technology to supply a set of solutions at a distance (Online Multimedia Educational Applications) for the acquisition and/or updating of knowledge, and there are many authors involved in its refinement (Machado, 2001; Rosenberg, 2001; Ryan et al., 2000).

According to Elliot Masie, one of the most respected and recognized specialists in this area, the excitement and commitment with which some countries, such as Portugal, embrace e-learning will make them progress at the speed of light (Machado, 2001). Steve Ryan believes that the development of e-learning, which is occurring in all types and at all levels of educational organizations (public and private), all around the world, is highly significant (Ryan et al., 2000). Whereas Marc Rosenberg considers that nowadays, almost all traditional American institutions for higher education are developing e-learning systems (Rosenberg, 2001), such systems are not limited only to higher education because, according to LeBaron, Laurel Springs High School was the first of its kind to implement all of its courses online (LeBaron, 2001).

The main reason for the growing popularity of this teaching method is the fact that it combines the advantages of using information technology in education (Azevedo, 1997) with the advantages of distance learning (Machado, 2001; Rosenberg, 2001); namely, access to information using the new instructional model "anytime, anyplace and anybody" (Aggarwal, 2000). These advantages, in relation to traditional study methods, are on the level of accessibility. Information:

- Is accessible to anybody at any time, anywhere (Aggarwall, 2000; Machado, 2001; Rosenberg, 2001)
- Is accessible through multimedia contents (Machado, 2001)
- Is ready to evolve at the student's individual rate (Machado, 2001)
- Uses hypertext (Machado, 2001)
- Focuses on the student – who is an active participant (Machado, 2001)
- Is available in module form (Machado, 2001)
- Relies on a flexible electronic infrastructure (Machado, 2001)
- Allows for simple and rapid updating (Machado, 2001; Rosenberg, 2001)
- Allows for a great diversity of operators (Machado, 2001)
- Works on individual programs (Machado, 2001)

The general advantages also pointed out are:

- Low cost (Machado, 2001; Rosenberg, 2001)
- Efficient proximity to an unlimited number of people (Aggarwall, 2000; Machado, 2001; Rosenberg, 2001)
- Feasibility of personalization (Machado, 2001; Rosenberg, 2001)
- Permanent availability (Machado, 2001)
- Ease of use. Does not require too much previous knowledge (Machado, 2001; Rosenberg, 2001)
- Universality, since it is based on Internet protocols which operate under standard protocols (Machado, 2001; Rosenberg, 2001)
- Promotion of the emergence of communities with common interests, functioning as a motivating factor (Machado, 2001; Rosenberg, 2001)
- Scalability, as it always allows inclusion of another person (Machado, 2001; Rosenberg, 2001)
- Promotion of a better collaborative environment (Machado, 2001)

- Justification and maximization of investments in intranet and Internet networks (Rosenberg, 2001)

In short, summarizing all that has been mentioned previously, and considering:

- All the advantages of utilizing multimedia and information technology in teaching
- The increasing importance of courses delivered through LDL
- The specific advantages of using e-learning systems
- The testimony of a wide range of known authors

… we can easily conclude that e-learning is here to stay and that it constitutes, on a worldwide scale, a new way of teaching that is redefining the concept of learning as we know it. That is, we are in the presence of an issue that offers great research prospects.

However, it is important to understand that technology is a tool and not a means in itself. It is absolutely vital that, in conjunction with technological investments, efforts be made to find methodologies, rules, guidelines and educational principles that are appropriate to the planning, development and evaluation of contents of this new way of teaching. The non-observance of this basic rule may lead to the development of systems that are technologically perfect but unable to fulfill their role from an educational point of view. This situation, for example, occurred in Portugal, when in the mid-nineties, companies concerned only with filling market niches started mass producing CD-ROMs, many of which were of low quality from a pedagogical point of view (Prata, 2000). In relation to e-learning, that imbalance is visible. It is noticeable that, with the majority of institutions (companies and schools, public and private) that have begun developing or are currently using e-learning solutions, the dominant concern has been essentially technological. That is, they have focused on developing the ideal platform in detriment of the educational slope, which should always be considered first when planning and developing contents for education.

One of the largest difficulties, despite more than four decades of research in human-computer interface areas, is that multimedia system architectures are still missing essential rules and guidelines for the association of different multimedia components. The use of contents with several types of multimedia components, such as text, graphics, image, sound, animation and video, is normally very attractive to users and helps retain their attention and interest during long periods of time. However, this is not the fundamental issue. What truly matters is to understand the real impact, in terms of efficiency and efficacy, these contents will have at the level of information processing and in the acquisition of knowledge. To achieve the desired efficiency and efficacy it is necessary, whilst developing the content, to consider the following factors:

- The way human beings learn
- The personal and cultural characteristics of the target population. Personal, amongst other things, in terms of age, education, previous knowledge, desires and expectations. Cultural, in terms of "certain cultural and policy cross-border peculiarities" (LeBaron, 2000)
- The specific characteristics of each component used (which, obviously, impedes to group or associate components randomly) (Chambel et al., 1998)
- The advantages and disadvantages of each component (for instance, video is, amongst all components, the most powerful in generating attitudes and emotions) (Guimarães et al., 2001)
- The specific characteristics inherent in the issues being presented (e.g., not appropriate to use the same methodology to explain such

different issues as literature and information technologies)
- The need to accommodate several different styles of learning (Chambel et al., 1998)
- The importance of interactivity and of active participation by the user (Chambel et al., 1998)
- The need for a virtual environment (learning environment) which facilitates the learning process. A learning environment is an active environment that infuses the user with a sense of mission that leads him or her to participate actively and to do things. It is an interactive environment (Abbey, 2000; Chambel et al., 1998).
- The learning process is a continuous one and not a set of sporadic and disconnected events (Machado, 2001).

In recent years, due to the growing success of the Internet, some authors have developed studies of generic rules/guidelines for the development of educational multimedia contents for the Web. Several universities have multimedia laboratories where these studies are made. Some of the most important are: the laboratories of the University of Alberta in Canada (Driedger, 1999), the University of Toronto (Drenner, 1998), Yale University (Lynch et al., 1999), the British Open University (OU) in England (Santos, 2000) and Universidad Nacional de Educación a Distancia (UNED) in Spain (Santos, 2000). However, the rules/guidelines defined by these institutions for the development of multimedia environments are few, generic, highly varied and constantly changing. From a study to compare different Web style guides it was possible to conclude that "sometimes they make quite similar recommendations for developing a web site, sometimes they disagree, and sometimes they emphasize different design considerations" (Berk, 1996). Specific rules which are defined and accepted world-wide do not even exist yet (DISA, 1995), which means that some empirical research is needed in order to determine/identify which design criteria will facilitate different online tasks.

This considerably aggravates some considerations/concerns previously pointed out as fundamental to the efficiency and efficacy of content development. These regard the selection of multimedia components to be used but more importantly the manner in which these components can be combined in user-friendly graphical interfaces and, simultaneously, be efficient from an educational point of view. The size and the implications of this deficit allow us to conclude that this is an area where a lot of development is needed and where any advance will be heartily welcome.

With the development of the OMEA our main goal was to facilitate access to information for anybody at anytime and anyplace; that is, to solve the students' problems in attending the face to face classes. Simultaneously, we were expecting to benefit from the advantages of using Web-based technologies as a teaching support inside and outside the classroom and to contribute to the modernization of the study methods used by students. Another goal was to acquire more experience in planning, developing and evaluating online educational applications. Taking into account the above-mentioned difficulties, we also committed to doing some research into the complex process of developing real educational, multimedia and interactive online applications.

ONLINE MULTIMEDIA EDUCATIONAL APPLICATION (OMEA)

As mentioned before, the OMEA main goal is to solve the students' problems in attending the face to face classes by facilitating access to information for anybody at anytime and anyplace. Thus, students who could not attend the *Organizational Multimedia* face to face classes were considered to be the target group for the OMEA and the most

important factor was to develop an OMEA that could best compensate for a student's absence. However, and since we also intended to use the application as a study support inside and outside the classroom, the application was developed so that the general student population could also use it.

All classes in the course are laboratory-based and last three hours. The first hour and a half is dedicated to theory (theory-based) and the remainder to practice (practice-based), that is, to the presentation of practical cases. Given that the educational software model used for the planning, development and evaluation of the OMEA relies on the initial development of a prototype (which, if proven efficient, will serve as the basis for the subsequent development of the final educational application), the OMEA will be, from this point forward, designated as a prototype.

However, the extension/diversity of the course content, which comprises classes covering six different themes, namely text, graphics, image, sound, animation and video, also had to be considered. There are lots of theories and experiments about learning at a distance, especially if we consider research conducted by the British Open University over the last 30 years (Santos, 2000). However, there are some difficulties inherent to the development of this type of OMEA. A universal "formula" capable of guaranteeing the success of applications does not exist and, in order to be properly presented, each theme has its own specifications and methodologies, especially with regards to practice-based classes where the differences appear the greatest. These were the reasons that led us to opt for the development of more than one prototype. As the approach to some of the above mentioned themes was similar, the decision was taken to implement four prototypes in the following order: the first with a practice-based class on image (Prata, 2003), the second with a practice-based class on sound (Prata et al., 2003b), the third with a practice-based class on animation (Prata et al., 2003d) and the fourth with a practice-based class on video (Prata et al., 2003c).

The prototypes were not developed simultaneously because:

- We wanted to learn from the different experiments; therefore a new prototype only began to be developed after the previous one had been concluded and tested
- From a technological point of view, the prototypes include components with different levels of complexity. In terms of manipulation, representation, storage, and types of resources needed, components may be classified in the following ascending level of complexity: image, sound, animation and video. Therefore, we decided to implement the prototype with a class on image first, and the prototype with a class on video last. This way we could count on some experience gained from our previous work. It is important to say that this last prototype was doubly challenging given that video is the most complex component, and although a great deal has been achieved in terms of improving compression algorithms and increasing bandwidth/access speeds to the Internet, we are still far from achieving the ideal
- We wanted to include as many groups of students as possible in the evaluation process. In fact, each prototype was evaluated by a different group of students. We paid particular attention to this question because we did not always want to bother the same students and we wanted each prototype to be evaluated by a new group that had never seen the previous prototypes. All the prototypes were evaluated by students taking the *Organizational Multimedia* course during the 2002/2003 academic year, both semesters.

Each of the four prototypes comprises three different sections: one section with the content of a practice-based class about a specific theme (image, sound, animation or video), the Frequently Asked Questions section (FAQs) and the exercise section (which includes solutions).

In conclusion, it is important to realize that the main goal of our work is to develop a final OMEA, which will include all the classes on the *Organizational Multimedia* course. However, as supported by the model we have used, we must start by developing and testing a prototype. As mentioned before, the content of the *Organizational Multimedia* course comprises six different chapters and our first thought was to develop a prototype for each chapter. Yet, after a detailed analysis we came to realize that some chapters included components with similar characteristics, so the final decision was to develop four prototypes: a first prototype with a practice-based class on image (Prata, 2003), a second one with a practice-based class on sound (Prata et al., 2003b), a third one with a practice-based class on animation (Prata et al., 2003d), and finally, a fourth one with a practice-based class on video (Prata et al., 2003c).

As part of a major project, the educational software model used for the planning, development and evaluation of the prototypes as well as the evaluation method used were the same in all four prototypes. Both the educational software model and the evaluation method used will be described in the next sections.

EDUCATIONAL SOFTWARE MODEL

Origins of this Model

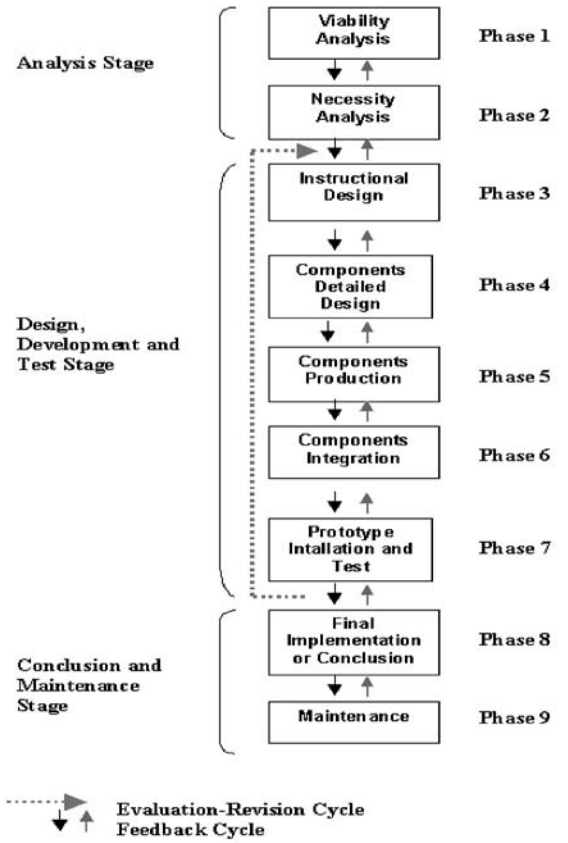
The model used for the planning, development and evaluation of the OMEA was a result of the integration of the model presented in the first author's Masters thesis (Prata, 2000; Prata et al., 2002) with methods (Sutcliffe, 1999), methodologies and guidelines proposed by other authors (Drenner, 1998; Driedger, 1999; Fernandez, 2000; Lynch et al., 1999; McGloughlin, 2001; Nielsen, 2000; Olsina et al., 1999; Salmon, 2000; Tsai, 2000; Vaughan, 1998; Vrasidas, 2000). The final model is composed of nine phases grouped in three different stages and, in very general terms, marks the initial development of a prototype, which, if proven efficient, will serve as the basis for the subsequent development of the final OMEA.

Structure of the Model

The final model, which can be seen in more detail in Figure 1, is composed of nine phases grouped in three different stages, namely: the analysis stage (phases of viability and necessity analysis), the design, development and test stage (instructional design, components detailed design, components production, components integration and prototype installation and test phases) and, finally, the conclusion and maintenance stage (final implementation or conclusion, and maintenance phases).

In general terms, the model marks the initial development of a prototype, which, if proven efficient, will serve as the basis for subsequent development of the final educational application. The software evolves according to an organized sequence of phases, in which the output of a given phase constitutes the input of the following phase. Each of these phases is composed of a varying number of tasks, which should be totally completed before moving onto the next phase. In an ideal situation the software would be developed following all phases of the model, in the exact order presented, and an efficient prototype would probably be obtained on the first trial. Unfortunately, things do not usually work out this well in practical terms. In reality, what happens is that it is frequently necessary to return to previous phases. These situations are also foreseen in the model, namely through the presence of feedback cycles in all phases. The tests or evaluations occur during

Figure 1. Detailed structure of the model



all phases and constitute the so-called formative evaluation. The final tests or summative evaluation only occur at the end of phase 7 and are meant to test the efficiency of the developed prototype. If the prototype is confirmed as efficient, then the remaining models are implemented following the same process. If the prototype is not efficient then we return to phase 3 of the model, or rather, we enter a evaluation-revision cycle.

It was noted that in all analyzed development models (lifecycle models and models for the development of educational multimedia software) there are phases and tasks, which, though bearing different designations, are common to most of the models. After analyzing each of these phases, their relevance to this work and the order in which they should be included in relation to the other phases, we reached the following final result:

1. Phase 1 – Viability Analysis
   - **Goal:** Analyze the viability of the project.
   - **Input:** Students' needs.
   - **Tasks:** Define without going into great detail:
     - The goals; the target population; the subject or domain; the choice of medium; tasks, resources, constraints and costs; alternative implementation strategies
   - **Output:** A viability report considering the alternatives.
2. Phase 2 – Necessity Analysis
   - **Goal:** Description of the situation and of the learning goals.
   - **Input:** Initial needs identified in the viability report.
   - **Tasks:** Detailed defining:
     - The make-up of the working and executive groups; a survey of field conditions; target population descriptions (knowledge, motivation, capacities, objectives and exceptions) and the choice of evaluation groups; learning necessities analysis and a hierarchy of learning objectives; subject analysis, problem description, objective and generic selection of components; selection of development environment (educational software model); analysis and multimedia tools selection.
   - **Output:** Needs specification; contents learning/educational structure (learning model).
3. Phase 3 – Instructional Design
   - **Goal:** Conceptual instructional design.
   - **Input:** Specific needs and learning model.

- **Tasks:** Instructional design (navigation, colors, background and feedback among others); contents structuring (division into hierarchical levels and prototypical schemes); instructional events identification and sequence (navigation maps, for instance).
- **Output:** General schemes of content structure and sequence of instructional events.

4. Phase 4 – Components Detailed Design
   - **Goal:** Detailed design the several structures.
   - **Input:** General schemes of content structure and sequence of instructional events.
   - **Tasks:** Creation of a detailed design of the several structures (general base layouts); also, creation of a detailed design of instructional events (base layouts for instructional events).
   - **Output:** Functional specification (detailed design of the base interface).
5. Phase 5 – Components Production
   - **Goal:** Collect all the components that are to be used.
   - **Input:** Functional specification.
   - **Tasks:** Distribute contents through base layouts; identification and detailed study of said components (general design of the prototype's interface); collect and/or produce the different components (editorial work) and script (detailed design of prototype's interface); proceed to final selection of the authoring system.
   - **Output:** All multimedia components that are to be used, alternatives, and script (detailed design of the prototype's interface).
6. Phase 6 – Components Integration
   - **Goal:** Conclude the prototype.
   - **Input:** Functional specification script and all multimedia components that are to be used.
   - **Tasks:** The integration of all collected and/or produced components.
   - **Output:** Concluded prototype.
7. Phase 7 – Prototype Installation and Test
   - **Goal:** To install the prototype, evaluate its efficiency and identify weak points.
   - **Input:** Concluded prototype.
   - **Tasks:** Prototype installation; prototype evaluation (to detect errors and evaluate its efficiency).
   - **Output:** The results of the prototype evaluation.
     - **NOTE:** If the prototype is not efficient, it is necessary to go back to the instructional design phase in order to proceed to its adjustment. This process is called the evaluation-revision cycle and it does not imply that all phases have to be repeated with the same degree of detail. Depending on the types of weak points and/or faults identified during the evaluation it is necessary to ascertain which phases need revision.
8. Phase 8 – Final Implementation or Conclusion
   - **Goal:** Conclude the educational application.
   - **Input:** Documents resulting from all previous phases, as well as the prototype.
   - **Tasks:** The correction of faults detected during the prototype's evaluation; the incorporation of any remaining modules in the prototype.
   - **Output:** Final educational application.

9. Phase 9 – Maintenance
    - Regular maintenance of the educational contents of the application is necessary in order to keep it up to date.

As a working philosophy, we decided to adopt an inherent characteristic of the Carrie Heeter model, that is, letting creativity decide the course of the software's design (Scarlatos, 1997).

The evaluation referred to in phase seven concerns the final tests to be conducted on the prototype. However, and even though this is not schematically represented in the model, intermediate tests should be carried out for all phases.

EVALUATION METHOD

Each one of the four developed prototypes underwent two kinds of evaluation:

- Formative Evaluation – which was based on the tests conducted during the entire development process (intermediate tests). This kind of evaluation was carried out by a team of two people from the work team, 10 people belonging to the target population, and four people belonging to a potential target population, that is, students from another Higher School, who also take multimedia classes. The goal of this kind of evaluation was to identify and correct problems during a preliminary phase and at the same time, to understand the students' expectations and preferences;
- Final Evaluation – which consisted of a final test or experiment and also of the handing out of a questionnaire, as will be described in the next subsections.

Final Test or Experiment

Students from the target population participated in this experiment, the goal of which was to evaluate the efficiency of the prototype as a substitute for the *Organizational Multimedia* face to face classes. The experiment is described below:

- As mentioned in previous sections, the *Organizational Multimedia* classes are laboratory-based and last three hours: one and a half hours are dedicated to theory and the other hour and a half is set aside for practice. Thus, to begin with, all students participated in a one and a half hour theory-based face to face class on the theme covered by the prototype.
- After that, there was an attempt to place the students in four categories: students with experience using the Internet (and with experience using the multimedia components used on the prototype), students with experience using the Internet (and with no experience using the multimedia components used on the prototype), students with no experience using the Internet (and with experience using the multimedia components used on the prototype) and students with no experience using the Internet (and with no experience using the multimedia components used on the prototype).
- After being placed in categories, the students were then distributed into two groups. Each group comprised the same number of students from different categories and occupied a separate classroom.
- One of the groups was submitted to the other hour and a half face to face class, which corresponded to the practice-based class (practical part of the laboratory-based class). Meanwhile, in the other group, each student for an hour and a half had access to the prototype which was meant to act as the substitute for the practice-based face to face class being attended by the others. This group of students used the prototype under the supervision of a teacher in order to guarantee obedience to the established rules.

During the practice-based face to face class we tried not to convey more essential information than was covered by the prototype. Thus, the students who used the prototype did not access less essential information than those who attended the practice-based face to face class did. What they did have, however, was access to a different teaching method with different characteristics.

- The prototype was installed on a public server and each user achieved speeds similar to those of a 56Kb-modem connection (the most frequent type of connection speed amongst the student population).
- Afterwards, all students were submitted to the same individual practical exercises.
- The next step was the analysis of results.

The students chosen were considered natural because they were in the last year of their degrees and, at the time, all of them were taking the *Organizational Multimedia* course.

By separating the student population into two groups and submitting each group to a specific situation (one of the groups having only studied using the prototype and the other group having attended the practice-based face to face class), we used an experimental methodology of the *between-groups* type, which seemed to most appropriate (Santos et al., 1999).

However, with the goal of improving the experiment, we considered the possibility of performing it in two different phases:

A first phase would be exactly what is described above and a second phase would involve changing groups: having the group that initially studied with the prototype now attend the practice-based face to face class, and having the group that initially attended the practice-based face to face class now study with the prototype. The studied contents could be:

- The same in both phases of the experiment, but in this case, it would not be the first time that the students were exposed to the subject matter, which would therefore carry a learning situation from the first phase of the experiment to the second. To solve this type of situation, what we could do would be to carry out the second part of the experiment after some time. However, that solution would have been impossible in this case as the students, who were in the last year of their courses, were about to finish school and obviously were not very committed to coming back later to participate in a new experiment. However, even if the experiment were possible, the experience of these students in using the Internet would not be the same, because the majority of them have easy access to these technologies and strong motivation to use them.
- Different in two phases of the experiment – if the contents used on the second phase of the experiment were different from the ones used in the first phase, then the second phase of the experiment could be conducted immediately after the first one. However, as the complexity level of the contents varies from theme to theme, and as the multimedia structure of the different themes is also different, the result will not be reliable. Another possibility would be to consider the population as an individual group and submit them to both situations: all students would be supposed to attend the practice-based face to face class and after that use the prototype, or vice versa. This methodology, of the "inside-groups" type, did not seem to be very appropriate because, from one situation to another, we will have situations of learning.

We can therefore conclude that the options referred to above work as a new experiment, similar to the first one, but not as a complement to it.

Questionnaire

The second part of the final evaluation was the use of a questionnaire. We were expecting to capture the students' reactions to the prototype, find out their opinions about it, detect technical failures, and collect some suggestions in order to improve it. As we wanted to include all the students in this evaluation, we had to partially repeat the final test or experiment. That is to say, after finishing the practical exercises, the groups were switched around. The group that had initially studied with the prototype attended a practice-based face to face class, and the group that had initially attended the practice-based face to face class studied with the prototype. After that, they were all able to voice an opinion about the prototype's characteristics and fill out the questionnaire.

We asked them to give their opinion freely (in writing and anonymously) concerning all details that they particularly liked and disliked. The students were encouraged to navigate around all the prototype's paths. No information was given (not even a manual or any previous tips) about using the prototype. While the students were using the prototype, they were observed in a passive manner. This gave us the opportunity to collect information about their reactions, expressions and behaviors.

RESULTS OBTAINED

Prototype with a Class on Image

In the final evaluation of the prototype, which focused on a practice-based class about image, 54 students participated (38 of whom with previous experience in using the Internet and 16 with no experience using the Internet). All the students experienced in using the Internet also had experience using image files). After the experiment and the submission of the questionnaire, the results were analyzed as follows:

Experiment Results

In relation to the experiment, in general terms, all students solved the exercises easily. However, the results obtained were different, as presented in Table 1.

In both situations (students with experience and students with no experience using the Internet) we tried to verify if the variables of grade obtained in the exercises and method of study used were or not co-related (dependent). As the sample size was considered small, we used Fisher's Test (Everitt, 1997) and we verified that the variables were not independent. That is to say that, in both situations, the grade obtained in the exercises was not independent of the study method used.

The experiment showed us that the majority of the students feel quite enthusiastic about using this type of online application and that its use may

Table 1. Average grades obtained by the students

	Students who initially used the **prototype**	Students who initially attended the **practice-based class**
With experience using the Internet and image files (**38** students)	**14**	13
With no experience using the Internet (**16** students)	13	13

have better results than previously expected. In fact, as this application is meant to be a substitute for attending classes, the main goal is to achieve the same results that we achieve with the classes, and this happened in the group of students with no experience in using the Internet. However, the results obtained in the group experienced in using the Internet were a little better amongst students who initially only used the prototype than the results obtained amongst those who initially attended the practice-based class (at an average of 14 against an average of 13). This probably happened because the class was about image, which is simple to represent and did not occupy too much space, when compared with more complex media such as sound, animation or video. In fact, the prototype, which was very easy to use and relatively fast, worked very well in terms of motivation. These results prove the efficiency of the prototype and are a good incentive to continue this work.

Questionnaire Results

As for the questionnaire, the direct answers are summarized as presented in Table 2.

It was noted, as expected, that the 38 students with experience in using the Internet were more demanding and, in fact, they are amongst the ones who classified the prototype as slow. Another factor was that although all students considered this type of prototype to be a good (51 out of 54) or medium (three out of 54) substitute for attending classes, only 45 out of 54 considered the studied prototype good enough to replace the class entirely. This probably indicates that there are still

Table 2. Answers obtained on the questionnaire

About the prototype:	Very	More Or Less	A Little	Very Little
1. Has an attractive design	42	11	1	0
2. The information is well organized	45	7	2	0
3. Navigation is simple and intuitive	37	10	7	0
4. The subject is clearly presented	49	5	0	0
5. Easy to use	44	10	0	0
6. Motivating	50	4	0	0
	Good	Medium	Weak	Poor
7. Number of examples presented	51	3	0	0
8. Number of exercises presented	41	10	3	0
9. FAQs section	53	3	8	0
10. Speed	29	16	9	0
11. Constitutes good method of replacing attended class	51	3	0	0
12. Global evaluation	40	11	3	0
	Yes		No	
13. A good enough substitute for the attended class?	45		9	

some improvements to be made to the prototype. In relation to the open-ended questions, students were asked to identify the strong points, the weak points and to suggest ways of improving the prototype. The strong points mentioned were that it helped students who could not attend classes (50 out of 54), that it was accessible from anywhere (51 out of 54), that it was motivating (49 out of 54), enjoyable (32 out of 54) and different from other study methods (43 out of 54). The weak points mentioned were average navigational structure (16 out of 54) and slowness (23 out of 54).

The majority of students considered that the prototype had an attractive design, that the information was well organized, that navigation was simple and intuitive, that subjects were clearly presented, that it was easy to use and motivating, that it presented an adequate number of examples and exercises and that it was a good substitute for attending classes. In fact, the only problems pointed out were a degree of slowness in downloading the prototype and an average navigational structure.

Prototype with a Class on Sound

In the final evaluation of the prototype, which included a practice-based class on sound, we had the participation of 82 students (16 students experienced at using Internet and sound files, 40 students experienced at using the Internet but with no experience of using sound files and 26 students with no experience of using Internet or sound files). After conducting the experiment and applying the questionnaire, the results were analyzed as follows.

Experiment Results

As for the experiment, in general terms, all students solved the exercises easily. However, the results obtained were different, as presented in Table 3.

With Fisher's test (Everitt, 1997) we verified that the variables (grade obtained in the exercises and study method used) were indeed co-related (not independent). That is to say that the grade obtained in the exercises did relate to the study method used.

As for the results obtained by students who initially attended the practical class and results obtained by students who initially used the prototype, there were some differences, namely:

- The results obtained among students with no previous experience of using the Internet

Table 3. Average grades obtained by the students

	Students who initially used the **prototype**	Students who initially attended the **practice-based class**
With experience using the Internet and sound files (**16** students)	14	**16**
With experience using the Internet but with no experience using sound files (**40** students)	13	13
With no experience using Internet and with no experience using sound files (**26** students)	12	12

or sound files (26 out of 82) and the results obtained among students with experience of using the Internet but with no experience of using sound files (40 out of 82) were more or less the same for both groups.

- The results obtained among students experienced in using the Internet and sound files (16 out of 82) were very good and even better among those who attended the class (an average of 16 against an average of 14). These students already had previous knowledge of sound subject matter and, as it was probably an interesting subject for them participated quite actively in class by asking several questions and expressing doubts, which were immediately clarified. Those who used the prototype may also have had their doubts but as they were not immediately clarified (they had to resort to the FAQ Section), their results were slightly worse.

These results were encouraging because in both groups (the group that attended the practice-based class and the group that only used the prototype) the majority of students achieved similar scores. The only category of students to achieve better averages in the group that attended the class (as compared to the average obtained by the group that only used the prototype) was the one with previous experience using the Internet and sound files (16 out of 82). However, these higher averages were the result of the personality and attitude of these particular students, who prefer asking the professor direct questions and obtaining rapid answers, rather than browsing

Table 4. Answers obtained on the questionnaire.

About the prototype:	Very	More Or Less	A Little	Very Little
1. Has an attractive design	58	18	6	0
2. The information is well organized	63	16	3	0
3. Navigation is simple and intuitive	68	12	2	0
4. The subject is clearly presented	69	13	0	0
5. Easy to use	67	13	2	0
6. Motivating	79	3	0	0
	Good	Medium	Weak	Poor
7. Number of examples presented	75	7	0	0
8. Number of exercises presented	50	22	10	0
9. FAQs section	72	5	5	0
10. Speed	4	34	36	8
11. Constitutes good method of replacing attended class	78	4	0	0
12. Global evaluation	51	30	1	0
	Yes		No	
13. A good enough substitute for the attended class?	68		14	

around the prototype looking for the answer. We consider that this problem can be solved with a more friendly and personalized FAQ Section.

Questionnaire Results

The answers are summarized in Table 4.

As we can see from Table 4, some attention needs to be paid to the results relating to the prototype lack of speed. It was noted, as expected, that the 56 students experienced in using the Internet were more demanding and, in fact, were among those who classified the prototype as slow. Another discovery was that although all students considered this type of prototype to be a "good" (78 out of 82) or "average" (four out of 82) substitute for attended classes, only 68 out of 82 considered the studied prototype good enough to replace the class. This indicates that there are still some improvements to be made to the prototype in order to make it more efficient and comparable to the attended classes.

In relation to the open-ended questions, students were asked to identify the strong points and weak points of the prototype and to suggest ways of improving it. The strong points mentioned were: the fact that it helps students who cannot attend classes (80 out of 82); it is accessible from anywhere (75 out of 82); it is motivating (79 out of 82) and it is a novel and original study method (73 out of 82). The only weak point mentioned was slowness (44 out of 82).

We saw that the students believed the prototype gave them autonomy (80 out of 82), flexibility (75 out of 82) in regard to their studies, and classified it as a motivating (79 out of 82) and novel (73 out of 82) teaching/learning process.

Prototype with a Class on Animation

In the final evaluation of the prototype, which included a practice-based class on animation, 68 students participated (16 students with Internet and animation file experience, 34 students with Internet experience but with no experience in using animation files and 18 students with no experience of using the Internet or animation files). After conducting the experiment and applying the questionnaire, the results were analyzed as follows:

Experiment Results

As for the experiment, in general terms, all students solved the exercises easily. However, the results obtained were different, as presented in Table 5.

With Fisher's test (Everitt, 1997), we saw that the variables (grade obtained on the exercises and study method used) were indeed co-related

Table 5. Average grades obtained by the students.

	Students who initially used the **prototype**	Students who initially attended the **practice-based class**
With Internet and animation file experience (**16** students)	14	**15**
With Internet experience but with no experience using animation files (**34** students)	13	13
With no experience of the Internet or animation files (**18** students)	11	11

(dependent). That is to say that the grade obtained on the exercises did relate to the study method used.

As for the results obtained by students who initially attended the practice-based class and results obtained by students who initially only used the prototype, there were some differences, namely:

- The results obtained by students with no Internet experience (18 out of 68) were the same in both groups.
- The results obtained by students with Internet experience but with no previous knowledge of animation (34 out of 68) were more or less the same for both groups.
- The results obtained by students with Internet experience and previous knowledge of animation (16 out of 68) were very good, and better among those who sat through the attended class. These students already had previous knowledge of animation and participated quite actively in class by asking questions and expressing doubts, which were immediately clarified. Those who used the prototype may also have had questions but as these were not immediately clarified (they had to use the FAQs section) the result was a slightly worse score.

These results were optimistic because in both groups (the one that attended the practical class and the one that only used the prototype) the majority of students achieved similar scores. The only category of students to achieve a better average in the group that attended the class, when

Table 6. Answers obtained on the questionnaire

About the prototype:	Very	More Or Less	A Little	Very Little
1. Has an attractive design	47	18	3	0
2. The information is well organized	60	7	1	0
3. Navigation is simple and intuitive	58	8	2	0
4. The subject is clearly presented	61	7	0	0
5. Easy to use	56	10	0	0
6. Motivating	63	5	0	0
	Good	Medium	Weak	Poor
7. Number of examples presented	60	7	1	0
8. Number of exercises presented	19	36	13	0
9. FAQs section	57	6	5	0
10. Speed	0	21	37	10
11. Constitutes good method of replacing attended class	59	9	0	0
12. Global evaluation	44	15	9	0
	Yes		No	
13. A good enough substitute for the attended class?	49		19	

compared with the average obtained by the group that only used the prototype, was the one with previous Internet and animation file experience (16 out of 68). As with the prototype with the class on sound, we believe that this higher average was the result of the personality and attitude of these particular students, who prefer asking the professor direct questions and thus obtaining rapid answers, rather than browsing around the prototype looking for answers. Probably, this problem will be solved with a more friendly and personalized FAQ Section.

Questionnaire Results

The answers are summarized in Table 6.

As we can see from Table 6, the majority of students considered the prototype "good" in general terms. However, some attention needs to be paid to the results relating to the prototype lack of speed. As with the previous prototypes, we also noted that although all students considered this type of prototype to be a "good" (59 out of 68) or "average" (nine out of 68) substitute for attending classes, only 49 out of 68 considered it good enough to replace the class. This indicates that there are still some improvements to be made to the prototype in order to make it more efficient and comparable to attending class.

In relation to the open-ended questions, students were asked to identify the strong points and the weak points of the prototype and to suggest ways of improving it. The strong points mentioned were the fact that it helped students who could not attend classes (58 out of 68), that access was possible from anywhere at any time (61 out of 68), that it was motivating (62 out of 68) and that it was a novel and original study method (36). The only weak point mentioned was slowness (47out of 68).

Prototype with a Class on Video

In the final evaluation of the prototype, which involved a practice-based class on video, 32 students participated (14 students with Internet experience and 18 students with no Internet experience). None of them had any previous experience of video files. As the size of the sample population was very small (because we were at the end of the semester), the results should be considered no more than a mere indicator, useful essentially for improving the prototype.

After conducting the experiment and applying the questionnaire, the results were analyzed as follows:

Experiment Results

As for the experiment**,** in general terms, all students solved the exercises easily. However, the results obtained were different, as presented in Table 7.

With Fisher's test (Everitt, 1997) we saw that the variables (grade obtained in the exercises and study method used) were indeed co-related

Table 7. Average grades obtained by the students

	Students who initially used the **prototype**	Students who initially attended the **practice-based class**
With Internet experience (**14** students)	12	**13**
With no Internet experience (**18** students)	10	**12**

(dependent). That is to say that the grade obtained on the exercises did relate to the study method used.

In general terms, both groups solved the exercises easily. However, in both groups, the results obtained among students who initially only used the prototype were worse than the results obtained among those who initially attended the practice-based class. These inferior results were especially noticeable among the students with no Internet experience. It was noted, as expected, that the 14 students with Internet experience were more demanding. However, they were much more tolerant of slowness while downloading the prototype components than the students with no Internet experience.

Questionnaire Results

The answers are summarized in Table 8.

As we can see from Table 8, the majority of students considered that the prototype had an attractive design, that information was well organized, navigation was simple and intuitive, that subjects were clearly presented, that it was motivating, that it presented a sufficient number of examples and exercises, and that it was a good substitute for attending classes. However, although all students considered this kind of prototype to be a "good" (27 out of 32) or "average" (five out of 32) substitute for attending classes, only 13 out of 32 considered the studied prototype good enough to substitute for the class. This indicates that there

Table 8. Answers obtained on the questionnaire

About the prototype:	Very	More Or Less	A Little	Very Little
1. Has an attractive design	25	4	3	0
2. The information is well organized	16	10	6	0
3. Navigation is simple and intuitive	11	17	4	0
4. The subject is clearly presented	23	9	0	0
5. Easy to use	3	11	18	0
6. Motivating	21	10	1	0
	Good	Medium	Weak	Poor
7. Number of examples presented	28	4	0	0
8. Number of exercises presented	26	6	0	0
9. FAQs section	24	6	2	0
10. Speed	0	9	17	6
11. Constitutes good method of replacing attended class	27	5	0	0
12. Global evaluation	3	16	13	0
	Yes		No	
13. A good enough substitute for the attended class?	13		19	

are still serious improvements to be made to this prototype in order to make it more efficient.

As for the open-ended questions, students were asked to identify strong and weak points and to suggest ways of improving the prototype. Strong points mentioned were the fact that it helped students who could not attend classes (20 out of 32), that it could be accessed from anywhere (26 out of 32), that it was motivating (17 out of 32) and that it was a novel study method (27 out of 32). The weak points mentioned were difficulties in using the prototype (25 out of 32), average navigational structure (15 out of 32) but, especially, slowness (24 out of 32).

From observing the students directly, we were able to see a great deal of enthusiasm when they started using the prototype. However, after some time they lost part of their enthusiasm and showed some impatience with the prototype's slowness.

For the first time in the course of these experiments, the results obtained among students (of all categories) who initially used the prototype were worse than the results obtained among those who initially attended the practice-based class. This probably happened because the class was about video, which is very difficult to represent/implement and resulted in a slow prototype. In this particular case, with all categories of students, the face to face class was more effective than the application.

FUTURE TRENDS

Regarding future work, we expect to conclude the implementation of the final OMEA with all the classes of the *Organizational Multimedia* course. This final OMEA, which is currently being implemented, as mentioned before is meant to substitute, in the best possible way, the face to face classes students could not attend. During the first phase the OMEA will be made available on the Internet, meaning it can be accessed by anyone, anywhere and at anytime (as an example, please check MIT's open courses, available at *http://ocw.mit.edu/index.html*). As the OMEA's main goal is to be an efficient substitute for the face to face classes, its contents are very complete and detailed, as to exactly reproduce the subjects delivered in those classes. The only thing that is different is the way in which the information is presented, because, obviously, it is adapted to be displayed in an online educational application. With this application, the student will be able to access from anyplace at anytime the content corresponding to classes that he or she missed. Creating this OMEA was the quickest and most efficient solution found to solve problems/difficulties inherent to student absences.

The Higher School of Management Sciences currently has several projects in place, namely, the implementation of an intranet and an e-learning system. Thus, and considering the OMEA's future integration in both systems, its contents are being developed in a modular fashion. This kind of development will allow the OMEA's integration with both projects' platforms and will also permit different ways to associate the contents/modules considering the required level of difficulty in each case.

Concluding, the goal is that in the future the OMEA is to be integrated and made available, in the following order, through the following systems:

- The Internet (which will help us to provide an educational environment that we classified as "online anytime, anyplace, anybody" model).
- The school's intranet (which will help us to provide an educational environment that we classified as "online in the studyplace" model).
- The school's e-learning system, and in that case it will have to be adapted to the teaching model being used (blended or exclusively online).

- Other standardized e-learning systems (LMS). In order to achieve this goal, the modules will have to be portable (multi-platform), interoperable and reusable, which is, according to Elliot Masie from the Masie Center, the present market tendency (Masie, 2004). However, and as this standardization process is already in a early stage and far from achieve universal and wide-world accepted standards (Holley, 2003), the integration of our application with other standardized systems will be the last part of the entire work.

The following describes the way in which the OMEA is supposed to be used:

1. **As a complete online substitute for the face to face classes students could not attend.** Pedagogically speaking, this is a learning model where students are at the center of the model, and we can call it online "anytime, anyplace, anybody". Some functionalities are currently being studied as to be implemented on a later stage of this work. Those functionalities include: "virtual post-its" that allow students to add their own comments and notes on the contents, exercise sections including exercises with answers and others only with the final result (solution), evaluation tests section, which will be automatically corrected by the system's application, FAQs section and personalized classes. These personalized classes will be manually or automatically generated using modules in which the student has shown most weakness with. Manually – through information obtained directly from students via an online form, where he or she notes the modules found to be the hardest; or automatically – generated by the application that analyzes results obtained on exercises and evaluation tests sections. Obviously, this last solution will only be available after obtaining some input on the student through the resolution of exercises and/or evaluation tests.
2. **As a tool to help/support the face to face classes.** In this learning model, which we can call "online in a classroom," the professor will be in control and is the center of the model. In fact this is like a traditional face to face class where the online educational application is made available not only as a background material but is integrated with classroom instruction as a classroom tool.
   Apart from the motivation associated with this learning model, one of the biggest advantages is that students learn with the professor how to use the application and thus need not do it on their own.
   The application will be used in the classroom to support the following tasks:
   - Examples demonstration – through the use of the application the students will, more rapidly, easily and efficiently understand the theoretical concepts. In our OMEA, and considering that the course classes are on multimedia, with a simple click students will, for instance, hear, see and compare sound and video files recorded using different quality parameters; see and compare the visual differences obtained after resizing images and after resizing graphics; compare the quality of an image recorded with different color palettes and compression algorithms; and so on.
   - Exercises resolution – through the use of the exercises section.
   - Evaluation tests – through the use of the evaluation tests section.
3. **In students' evaluation processes.** Through the evaluation tests section, and similarly to what can be achieved with the WebCT, once all students are connected, the application will allow them to solve the same test.

However, and in order to avoid any cheating, the questions will be presented in a different order to every one of them. The tests will be automatically corrected by the system's application, which brings some obvious advantages: the results will be quickly known and the professor will have more time to spend with more important tasks such as supporting and helping students with their learning process.

4. **As a regular study tool/support.** Which will be very useful for students because the application includes an exercise section, evaluation tests section and a FAQ's section.

   Another advantage may be what we have decided to call the "dejá vu learning advantage": the application's contents are made available in the exact same order and level of complexity as the contents presented at the face to face classes, thereby making it easier to remember and memorize these when studying.

CONCLUSIONS

Mainly in order to make information easier for students to access at any time from any place, we decided to develop an Online Multimedia Educational Application (OMEA) to aid in the teaching of the *Organizational Multimedia* course. Others goals were to benefit from the advantages of using information technologies (namely Web-based technologies) as a teaching support inside and outside the classroom, to contribute to the modernization of study methods used by students and, finally, to acquire more experience in planning, developing and evaluating OMEA. The *Organizational Multimedia* course is taught to students in their fourth year at the Higher School of Management Sciences, where the first author teaches. In order to plan, develop and evaluate this type of application, the use of adequate models is highly recommended. The model followed and described in this chapter involves the initial development of a prototype, which, if proven efficient, will serve as the basis for subsequent development of the final application. As the *Organizational Multimedia* course is made up of six different chapters: text, image, graphics, sound, animation and video, our first thought was to develop a prototype for each chapter. However, after more detailed analysis, we noticed that some chapters include components with similar characteristics. Thus, the final decision was to develop four prototypes in the following order: a first prototype with a practice-based class on image, a second one with a practice-based class on sound, a third one with a practice-based class on animation, and finally, a fourth one with a practice-based class on video.

As part of a major project, the model used to plan, develop and evaluate the prototypes as well as the evaluation method used were the same in all four prototypes. Both the model and the evaluation method used have been described in this chapter.

The final evaluation of the prototypes was made up of two parts: an experiment and a questionnaire, both requiring the participation of different categories of students. However, as the sample size was considered medium or small in all four experiments, the results achieved should be considered merely indicative, and useful for improving the prototypes.

In general terms, the experiments (four: one for each prototype) showed us that the majority of students felt quite enthusiastic about using this type of application and that it may have better results than expected. In fact, as this application is meant to be a substitute for attending classes, the main goal is to achieve the same results we achieve with face to face classes, and that happened with the majority of the prototypes and categories of students, as we can see in Table 9.

As we can see from Table 9, in general terms, the prototypes were efficient with 70% (54.5% +

Table 9. Results obtained for all four prototypes.

	Number of students whose results with the prototype were worse than results achieved with the face to face class	Number of students whose results with the prototype and the face to face class were the same	Number of students whose results with the prototype were better than results achieved in face to face class
Prototype with a class on image: (tested by 54 students)	0 (0%)	**16 (29.6%)**	**38 (70.4%)**
Prototype with a class on sound: (tested by 82 students)	16 (19,5%)	**66 (80.5%)**	0 (0%)
Prototype with a class on animation: (tested by 68 students)	16 (23,5%)	**52 (76.5%)**	0 (0%)
Prototype with a class on video: (tested by 32 students)	**32 (100%)**	0 (0%)	0 (0%)
Total (246):	**64 (26%)**	**134 (54.5%)**	**38 (15.5%)**

15.5%) of the students. However, when we consider each prototype separately, we can see that:

- The prototype with a class on image worked even better than expected. In fact, 70.4% of the students achieved better results with the prototype than by attending face to face class.
- The prototype with a class on sound needs to be improved. There is a particular category of students (those with Internet and sound file experience – 19.5%) who achieved better results by attending the face to face class than with the prototype. As this category of students is more demanding and dependent upon direct student-teacher interaction, one solution may be the improvement of the FAQ section.
- The prototype with a class on animation needs to be improved. There is a particular category of students (the ones with Internet and animation file experience – 23.5%) who achieved better results by attending the face to face class than with the prototype. As this category of students is more demanding and dependent upon direct student-teacher interaction, one solution may be the improvement of the FAQ section.
- The prototype for a class on video needs to be completely reformulated because 100% of the students obtained worse results with the prototype than by attending the face to face class.

It was possible to note from the questionnaires that the majority of students considered the prototypes to have an attractive design, to contain well organized information, to feature simple and intuitive navigation, to present subjects clearly, to be easy and motivating, to contain a sufficient number of examples and exercises, and to be a good substitute for attending classes. As for weak points, it was also possible to obtain enough feedback to improve the prototypes. In fact, the only problems consistently reported were slowness (in all the prototypes) and only average navigational structure in two prototypes (the prototype with a class on image and the prototype with a class on

video). In the prototypes with classes on sound and animation we felt that the FAQs sections had to be improved in order to become more user-friendly and personalized for a particular category of more demanding students, and those more dependent on traditional student-teacher interaction.

The results obtained were very encouraging and showed us that the production of this type of online applications should be encouraged. The enthusiasm and the results achieved by using the prototypes justify further development work, and at present the prototypes that were already perfected are being now used in the implementation of the final OMEA. As the Higher School of Management Sciences has currently several projects in place, namely, the implementation of an intranet and an e-learning system, the final OMEA contents are being developed in a modular fashion in order to be easily integrated with both systems. So, the goal is that in the future, the final OMEA may be integrated and made available, in the following order, through the following systems: the Internet, the school's intranet, the school's e-learning system and, when possible, in other standardized e-learning systems (LMS). As to the way in which the OMEA is going to be used: as a complete online substitute for the face to face classes students could not attend, as a tool to help/support the face to face classes (in the following tasks: examples demonstration, exercises resolution and evaluation tests), in students' evaluation processes and as a regular study tool/support.

Concluding, in a general way the use of these types of OMEA, inside or outside the classroom, brings considerable benefits to its users (students and professors), namely:

- Students who cannot attend the classes have access to the exact same contents presented at those classes without depending on others for help.
- Contents are available to anybody at any time from any place.
- Students easily understand theoretical concepts when associated with practical demonstrations via multimedia files with images, sounds, animation and video.
- Students in face to face classes do not need to be constantly concerned on taking notes all the time and may therefore instead pay more attention, dedication and immerse themselves in the learning process itself, by analyzing practical cases, solving exercises or simply discussing the subjects with the professor and colleagues.
- Professors have more time and feel more free to attend to students' solicitations and doubts;
- Students feel more motivated not only because they are using information technologies inside and/or outside the classroom but also because they are using real online multimedia educational applications and because their study methods are being modernized.

In conclusion, this was a worthwhile project since the goals were achieved. Considering that the development of this type of application is a complex process, the results obtained with the prototypes of the OMEA were very good, indeed better than expected. This project also allowed us to see that students are enthusiastic about learning through this type of applications and are prepared to use them.

A fundamental contribution to the prototype's success was the use of the educational software model described in this document, which for its simplicity of use and intuitive design we consider important to recommend.

Finally, with this work we contributed to the modernization of the study methods used by students and we have acquired more experience in planning, developing and evaluating Online Multimedia Educational Applications.

Chapter 4.10
Interactive Systems for Multimedia Opera

Michael Oliva
Royal College of Music , UK

ABSTRACT

This chapter considers the development of systems to deliver multimedia content for new opera. After a short overview of the history of multimedia in opera, the specific requirements of opera are analysed, with emphasis of the fundamental musicality of operatic performance. Having considered the place of multimedia elements in the narrative and acting space, the relevance of previous practice in electroacoustic music and Vjing is considered as a model for a working approach. Several software and hardware configurations explored, including the use of gestural control by the actors themselves. The creation of a keyboard based "video instrument" with a dedicated performer, capable of integration into the pre-existing musical ensemble, is recommended as the most effective and practical solution.

INTRODUCTION

By definition, opera and musical theatre should be the ultimate multimedia experience, and new technologies are bound to become an ever increasingly important part of this art form. Indeed, I would go further and suggest that the inclusion of computer sound and video is essential to the development of the form in our new century, expanding its range hugely and bringing much needed new audiences. In particular, we need to recognize the highly visually sophisticated nature of modern audiences, who have learnt the languages of cinema and television from birth, using these techniques to enhance our storytelling in opera and creating works of contemporary relevance. It is "an honest expression of the life we're living now" as Steve Reich, an important pioneer in this field, says (Reich & Korot, 2001).

Developing suitable interactive systems will be a part of bringing new media into the fold, so that they work successfully with what is there already. At its best, the experience of live opera, both large- and small-scale work, can be overwhelmingly powerful. I am convinced that much of this power derives from the fact that it is live, and that we are aware of the fragility and variability of what we are seeing. Also, the original conception of opera as "drama through music"

still applies, not that music is the most important element, all should carry equal weighting, but it is the music that is at the helm, so to speak, and musicality has to be a key principle. It is vitally important not to lose this in the push to include computer sound and video, and this is all too easily done. In particular, the marriage of prerecorded material with live elements needs to be very carefully handled so that the performers do not feel straight jacketed, as this is immediately deadening. As far as possible, the performers and conductor must have the freedom to drive the work along and interpret it as they wish, and any system we use for delivery of the media should enable this, responding to the energy of a particular performance, and functioning in an essentially musical way.

In order to achieve a successful integration, it is just as important that the use of computer sound and video is written into the work from the outset, as an integral part of the story to be told. To use these elements purely atmospherically or decoratively is to miss the point. These additions are capable of so much more than this, creating entire layers of narrative and character, defining worlds for these characters to inhabit, and alternative timelines for them to move in. In parallel with recent instrumental electroacoustic music, the design and implementation of the system itself is a significant part of the score, with the nature of the interface between person and machine informing what is possible. Clearly, what is said will adapt itself to the nature of the medium, and this will have an effect on the content of such works and the way that they are staged.

It also has to be recognised that even small-scale opera involves the collaboration of a rather large number of people, all of them trained specialists, from conductor to stage manager, working together in, hopefully, a highly organised way. Over the centuries, chains of command have developed that are logical and effective. Therefore, careful thought must go into developing systems that are appropriate to this type of collaborative ensemble. What may work for one form of multimedia production may not work here.

Thanks to advances in computer technology, the creation of such works has become a real possibility and, drawing from my own experience of composing and producing multimedia opera and electroacoustic music, I will set out and evaluate the types of interactive systems that might be best suited to the task, exploring in detail the requirements for what is to be achieved and the software and hardware possibilities. I shall investigate the nature of a practical interface with singers, ensemble, and conductor (as well as other elements of stagecraft such as lighting and set design) and how this is to be achieved.

BACKGROUND

The use of the moving image has a venerable history in opera. During the second phase of composition of *Lulu* (1929-1934), Alban Berg included a "film music interlude" between Act II i and II ii, and inserted a "film music scenario" in the short score of the opera. The film music interlude was to accompany a silent film that continued the action, showing events that could not be shown onstage, with annotations in the score indicating how images and actions would correspond to the music, and this was realised after Bergs death at the 1937 premiere (Weiss, 1966). More recently, Tod Machover' *Valis* (1987) (Richmond, 1989), Steve Reich's *The Cave* (1993) and *Three Tales* (2002)—described by Reich as "music theatre video" works (Reich & Korot, 2001)—and Barry Truax's *Powers of Two* (1995) (Truax, 1996) represent much more complete and successful integrations of video and computer sound into operatic storytelling allowed by considerably more advanced technology.

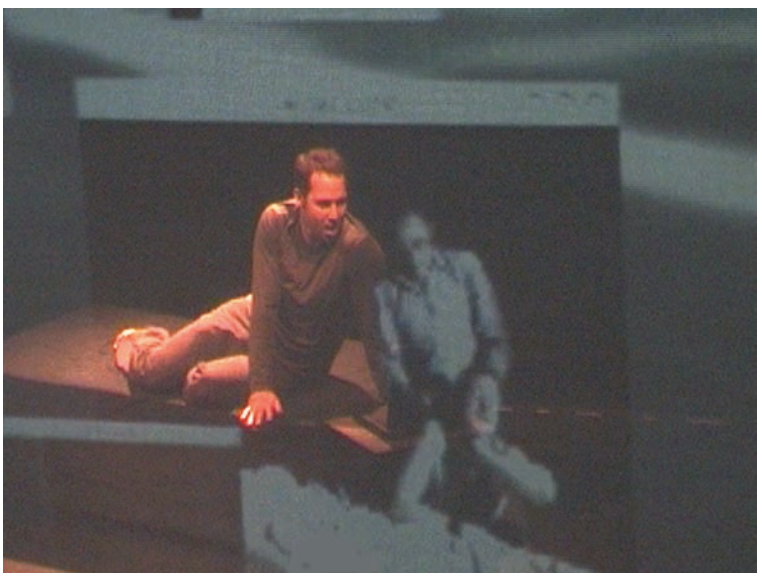
But in all these cases, video is not generated live, so the incorporation of these elements into theatrical work presents performers with a significant problem: Who owns time? Prerecorded com-

puter sound and video naturally have a tendency to "own time," running, as they are wont to do, at fixed rates. If there is to be close synchronisation, once a sequence has been triggered everyone has to play along. Moment to moment flexibility in tempo and interpretation are largely ruled out, and although there is the possibility of rubato at extremely small scales, depending on the rhythmic quality of the passage in question, there is no interactivity between events onstage and this sort of video or computer generated material.

In my own *Black and Blue* (2004) (Oliva, 2004), this problem was not resolved. The piece uses many long cued video and audio sequences and requires highly accurate synchronisation between image, action, and sound. Initially, the video represents the central character's real-time experiences viewing Web cams and in online video chatrooms, although as the drama unfolds, the narratives of the online, imagined, and real worlds become increasingly confused. The action is fairly evenly spread between these worlds, and integration was achieved by projecting the video onto a gauze screen that filled the front of the stage so that by carefully controlling lighting levels, the singers could be made to appear and disappear within the images. A second gauze at the back of the stage allowed for more complex layering. Video remained entirely in the digital domain, taking the form of a series of Quicktime .mov files on a laptop, organised into a playlist. The laptop was connected directly to a data projector, much as one would for a Powerpoint presentation. In contrast with previous tape-based systems, this allows for frame-accurate synchronisation between the image and music.

Although sequences were cued in the score to ensure sync with the live performers, the conductor worked to a click track generated by the computer, much as they might in the recording of music for film or TV. This system was simple, using commercial sequencing software that provided instantaneous response for accurate cueing. This worked, was reliable, and given the very driven nature of the story (a sort of high speed Faustian descent into hell) and score, it could be said that the overall effect was successful. However, it also proved incredibly burdensome on the performers, particularly over the large timescales involved (90 minutes).

Figure 1. A character watches an online murder in Black and Blue. The video is projected onto a gauze in front of the acting space



It could be argued that this was simply a skill for them to learn, one increasingly demanded in modern music making, and this view has some validity, but it is also the case that this method robbed talented performers of some of their most highly developed and cherished skills. To give of their best, singer/actors need to feel ownership of the music and dramatic pacing. This ownership allows them to project personality, which in turn greatly assists in the development of character. Another part of this ownership is that they need to feel safe. Mistakes can and do happen, so there should be the flexibility to allow for recovery in these situations, as is the case in more traditional acoustic performance. This safety relieves stress and lets the singer focus on the fine detail of their acting, leading to much more successful results.

I believe that a truly satisfying operatic or theatrical experience depends fundamentally on the ability of the singer/actors to shape the flow of time, using fluctuation in tempo as an expressive tool both at the level of a single phrase or gesture or over the course of an entire scene or act. My own experience in less technological theatre and music making shows that a work may show large variations in timing from night to night without it being noticeable that one performance was particularly slower or faster than another. An audience's sense of pace is a relative thing, and context is everything, so the variable, in-the-moment responses of a good performer are a key part of what we seek as members of that audience. This, above all, will draw us into the work and make us care about the characters.

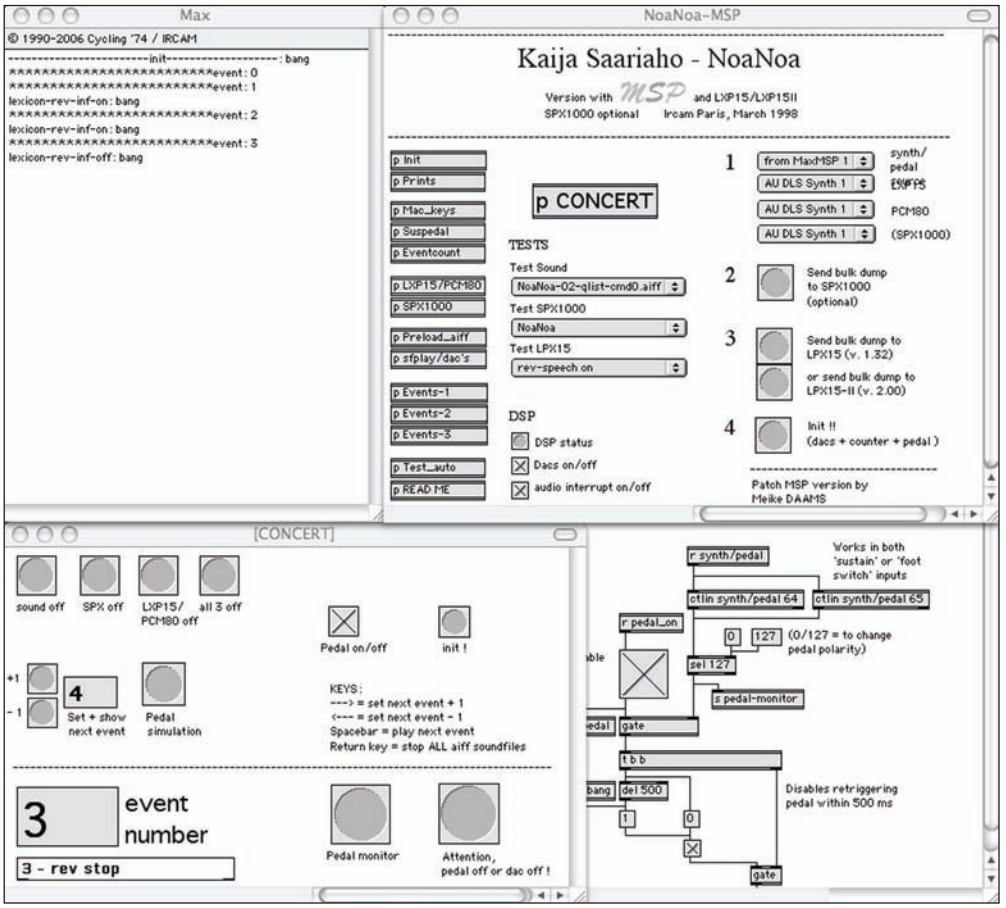
THE RELEVANCE OF ELECTROACOUSTIC PRACTICE

The development of electroacoustic music incorporating live instruments, over the last 15 years or so, provides an enlightening backdrop to the problem since this field presents us with a microcosm of our problem. It is also an area where a range of effective *musical* practices is beginning to be established and so offers glimpses into our future. Here only electronic or computer sound has to be delivered into a live setting. At a very basic level, adding video will simply be a matter of greater computing power, more disk space, and increased bandwidth, the principles remaining the same.

Without a doubt, the most significant development here has been the creation of flexible computer programming software environments such as MAX/MSP (Tools for New Media, n.d.), Pd (About Pure Data, n.d) and Supercollider (McCartney, n.d.). These provide the ability to process and/or create sound in almost any way imaginable. For example, live sound input from microphones can be processed in an incredibly wide variety of ways, an unlimited number of soundfiles/samples of practically any size can be played on cue, one can build synthesisers or samplers and incoming audio can be analysed and new musical material generated in response to it. The software can be controlled over MIDI (MIDI Manufacturers Association, n.d.) or Open Sound Control (Wright, 1997), high speed digital communications protocols, allowing use of a broad range of hardware controllers. Importantly, one can create a highly customised software configuration (known in MAX/MSP as a patch) for a particular piece, designed to work with a suitable hardware combination. One of the charms of these software packages is that they are absolutely open-ended, since you program from a very low level up. Although this can mean some hard work at the beginning, it has the considerable advantage that, unlike many music applications, no assumptions are made about what you want to achieve or how you might go about it, leaving you at the mercy of your imagination.

Kaija Saariaho's *Noa Noa* (1992) (Noa Noa, n.d.) for solo flute and "electronics" provides a very early but highly successful model of the sorts of interactive system one can build using this sort of

Figure 2. Computer (MAX/MSP) interface for Kaija Saariaho's Noa Noa. (1999, Chester Music Ltd. Used with permission.)



software. The original form of the piece requires a single computer running MAX/MSP for sample playback and two Lexicon PCM81 effects units controlled via MIDI, but in subsequent forms, the effects processing has been incorporated into the MAX/MSP patch to minimise the use of hardware. A microphone picks up the flute and passes the sound into the computer to be processed (via a multichannel audio interface); this is mixed with soundfile playback, and distributed over an eight-channel speaker system.

Control of the entire system is effectively in the hands of the flautist by means of a simple MIDI sustain pedal that needs to be depressed at cue points marked in the score. In the course of the roughly 10-minute piece, there are 64 cue points, and what happens at any particular depression of the pedal is entirely dependent on which cue number one is at. One of the 33 soundfiles might be played, the sound may move to a particular position in the eight-speaker array, some form of reverberation or harmonisation (pitch shifting) of the live flute sound may be applied, or perhaps a combination of these elements. To rehearse from anywhere in the score, one simply specifies the next cue point to be hit. This is all written into the patch in what amounts to an extra layer of the score.

The result is an incredibly beautiful, free and moving piece of music that always feels as if the flautist is in control of his or her expression. The way that the prerecorded soundfiles are used is

very interesting here. They are all short (ranging in length from 33 to less than 1 second), and in the parts where they are closely spaced, can overlap quite successfully (in the case of a fast performance). As a result, the flautist is always absolutely in control of the rhythm of any section. Many of the sounds are also derived from flute recordings, which creates a very close blend and dialogue with the playing. Combining this with the real-time treatments, it often becomes unclear whether the source is electronic or live. As a result, Saariaho's very careful conception and preparation of materials lets her create an integrated, expressive piece, and the listener hears something complex and vital that definitely belies the use of what might seem like a simple "on" button.

To some, the nature of the interaction between the flautist and computer (the pedal) may seem incredibly simplistic, given that it is now entirely possible to devise systems, such as gestural control, in which extra sensors applied to the instrument could be used to generate data that will control the computer (Diana Young's Hyperbow project for string instruments (Young, 2002) being a very interesting example of this). But it must also be remembered that purely in terms of flute technique, this is already a demanding piece, pushing the limits of what the instrument is capable of. So as far as the flautist is concerned, this simplicity is, in fact, a great strength. It lets them concentrate on their greatest skill, playing the flute beautifully. Many musicians actively dislike being "wired up to complicated systems" (to quote one I have worked with), despite having a real enthusiasm for working with new media. This is not being a Luddite, but rather a concern that their virtuosity and sound will suffer as a result of being distracted. If we want our work to be performed often by more than a just few specialists, we need to accommodate these concerns. Musicians need to enjoy their work to give of their best.

Saariaho's liking for simple interfaces can also be seen in her opera *L'Amour de Loin* (2000) (L'Amour de Loin, n.d.), where she uses a standard full-size MIDI keyboard to cue 88 eight-channel soundfiles. In the course of the entire opera, the pianist in the orchestra (in addition to their other duties playing a normal piano) simply plays a rising chromatic scale from the bottom to the top of the keyboard as indicated in the score- incredibly simple in performance and rehearsal, and incredibly effective.

More recently we have begun to see the development in electroacoustic music of a dedicated performer at the computer (or whichever interface is used), as an equal partner in the ensemble. This approach has much to recommend it. In my own *Xas-Orion* (2001) (New Ground, 2003) for oboe, cor-anglais, and computer, which again uses a MAX/MSP patch, the computer is performed directly from its alphanumeric keyboard using a "next cue" system, similar to that used in *Noa Noa*, combined with direct control of sound processing. So, for example, holding the letter D down will increase input of the oboe into the pitch shifting system, and holding F down will reduce it. This system works well with minimal hardware (just the laptop and PA), but for more intuitive and flexible control, these functions are also mapped to a hardware MIDI fader bank, in my case a Behringer B-Control BCF2000 (B-Control Fader BCF2000, n.d.), that connects directly to the laptop over USB.

In recent years, there has been an explosion in the use of systems like this, based as they are on relatively cheap, commercially available technology, and they represent a new type of musical instrument in their own right, which needs to be learnt just as one might learn to play the clarinet. This has developed naturally from recording studio technology, where, after all, most electroacoustic composers learn their craft; so these instruments usually combine familiar features from mixing desk and computer operation with the occasional use of MIDI keyboard and foot pedal controls. Subject to evolution over the years, these types of hardware control are not as arbitrary as

they may seem. They have proved themselves to be effective, providing (when well engineered) the sensitivity and good tactile feedback we find in other musical instruments. A less common, but highly effective device that can be added to this type of set up is Yamaha's excellent BC3A (Wind Guitar and Foot Controllers, n.d.), which generates MIDI from a small breath-sensitive mouthpiece. With a combination of these tools, we can easily provide enough simultaneous dimensions for control of the software, if this is intelligently laid out, always bearing in mind as we create the work how practically it is to be performed.

As works like *Noa Noa* show, the success or failure of these systems lies much more in how the software has been configured to work for, and as a part of, the piece in question than in the details of the hardware. Quality of content and flexibility of delivery can more than adequately compensate for simplicity of execution.

This instrumental approach also fits naturally into the world of music-making. Whether working from a score or improvising, traditional skills of ensemble playing, listening and response are still used in a way that other musicians can relate to easily and quickly.

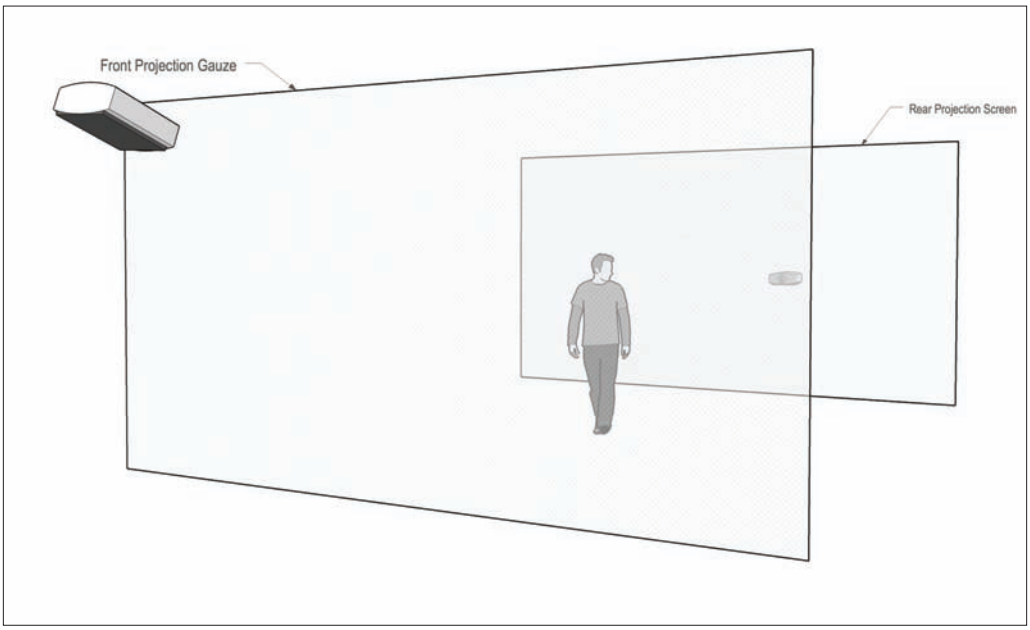
INCORPORATING VIDEO: REQUIREMENTS

Before we can design a system to deliver video elements for opera, we need to have a clear idea of what our ideal requirements are. I believe we should aim to produce works that are highly integrated and utilise the full range of possibilities offered by the moving image. As the most recent addition to an established art form, it is important that video never seems like a tacked-on afterthought, so we have to integrate on three levels: space (in terms of how video works on stage), narrative (content), and time (synchronisation).

The placing of video into the acting space needs careful consideration, and is a significant part of the initial design process. The mismatch between its essentially two-dimensional nature and the three dimensions of the theatre can be problematic, especially if there are significant interactions between what is live and onscreen. Multiple layers, involving several video projectors and the use of gauze screens, can provide a very good solution to this. Flat screens are, of course, not the only surfaces one can project on to, but the use of more interesting shapes may require some form of geometry correction so that the image does not become distorted undesirably (this is often required for situations where the projector is off axis to the screen anyway). Video projectors can do very simple geometry correction to remove keystoning, but anything more complex will have to be handled by computer software. It is also worth remembering that front projection directly onto the actors will throw shadows and can be rather blinding for them, possibly interfering with their ability to see the conductor. This can have disastrous consequences, so if space allows, rear projection is preferable. In my own experience, a combination of rear and front projection can be made to work very well. An additional consideration is whether the actors can actually see the video they are to interact with, and hidden monitors may have to be provided to assist with this.

Modern audiences are very fluent when it comes to receiving information through imagery, so we do not need to shy away from using video that contains important narrative strands, providing information that is essential to the dramatic development. For an effective blend, information content should be distributed evenly between all the elements of the opera-words, action, images, and sound-and this has to be written into the work, from the outset, with a clear understanding of why any particular piece of information is using a particular medium. Video allows us to incorporate text or graphics (moving or static), be used as an extension of lighting or set design, show our characters participating in events that

Figure 3. A simple, but highly flexible, stage layout allowing layering of imagery



do not take place on stage, or present them in other places or times. It enables presentation of multiple simultaneous viewpoints. An important part of this is that at different times in the work, we see the actors both live and on screen, and this could be achieved both by filming them beforehand or using live video from cameras that could be on or offstage. Using both, with the ability to composite these video streams live, can produce some startlingly effective results.

Video can be transformed in real time through the use of a very wide range of effects: adjusting colour, position, granulation, and so forth. This is not always as exciting as it may at first appear, and has to be used with caution, but is capable of adding meaning and expression in some very interesting ways.

Tight synchronisation between music, action, and video is essential for opera. Obviously, words and music are completely locked together in that they are sung, and this naturally leads on to synchronisation of action and music. This is a basic condition for this art form, and video must participate on equal terms. As we have already discussed, there is also a need for flexibility in tempo, leading to variability in the flow of time. So we need let the video follow the music (conductor or singer), standing the relationship we are familiar with, from film or TV, on its head. This requires a flexible and accurate cueing system; flexible enough to follow the score in real time and fast enough to respond instantaneously. Drawing again from the example of *Noa Noa*, the best approach would seem to be to use many short cues to piece the video together, but somehow achieve this without producing something choppy and fragmented. The rate at which we cut or dissolve from one image to another has great expressive effect, and is part of the language of film that we all understand, so this has to match the tone of the scene in question. Layers of video that can coexist would seem to be a solution to this problem. The overall effect required is deconstructed into smaller units that are then reassembled in real time. These can be divided over multiple screens or within one projection. If we are using

prerecorded clips, it is clear that they need to be of sufficient length to get from onset cue to offset cue at the slowest imaginable tempo (in other words, they should all be longer than is absolutely necessary). In terms of significant information content, these clips need to be "front weighted so that in a particularly fast performance, we do not cut away before the important event or image is shown. Another means of providing variable length for cues is being able to vary the frame rate in real time. This can be very effective, but is not appropriate for all types of material. For example, we are very sensitive to speed when viewing scenes of people in action, so a sense of slow-motion in this kind image may not be appropriate to the nature of the drama at that time. For film of clouds passing overhead, speed variation can be much less noticeable. Live video streams are, of course, inherently flexible, making them ideal in this situation, but there has to be a justification for using them rather than watching it happen on stage, and there are limitations on what you can set up. Again, a system that allows compositing in real time with other material would have great advantages. As we can see, the nature of the video material, and how it can be de- and reconstructed, is of great importance to the success of building a system that allows temporal flexibility, with content and form working together to achieve this.

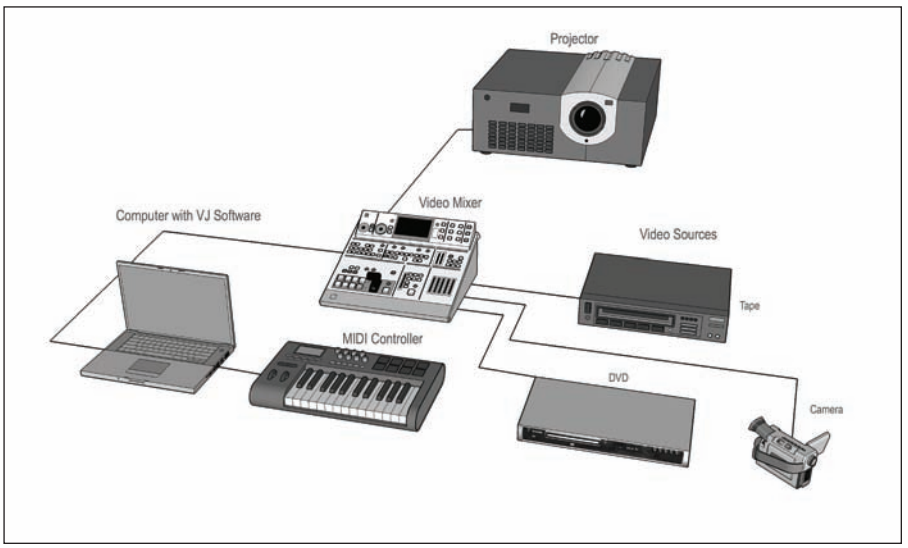
Clearly, the use of all these different layers will produce work of considerable complexity that will require careful preparation and planning. For *Black and Blue* (2004), we produced a cinema-style storyboarded script at a very early stage of the creative process, which proved immensely useful. This script was then regularly "cross-checked" with regards to practicality of means of production and design, and updated as our conception of the piece developed during writing and composition, with the rule that whenever we decided to include something, we had to be able to answer the question of how it was going to be done. Later, it became very easy to extract lists of sequences that needed to be filmed; images, graphics, and sounds to be collected; props required; and so forth, from this master script, as we progressed towards production.

Although based in the world of theatre rather than opera, *Super Vision* (2005) provides an inspiring example of what we can hope to achieve. Produced by the New York based Builders Association (The Builders Association, n.d.) and dbox (dbox dialog, strategy and design, 2005), the piece explores how we now live in a "post-private society, where personal electronic information is constantly collected and distributed. The data files collected on us circulate like extra bodies, and these 'data bodies' carry stains that are harder to clean than mud or sin" (Super Vision, n.d.). The piece effectively fulfils the requirements, outlined previously, on all three levels. The design of the stage space and use of multiple layers of projection is beautifully conceived, and the themes of surveillance, digital communication, and identity theft naturally lend themselves to, and provide opportunities for, the chosen media in compelling ways. Synchronisation is seamless and precise, responding organically to the pacing of the scenes. It is a short step from this kind of work to a form of opera that is equally satisfying.

INCORPORATING VIDEO: PRACTICE

Developments in computer software and hardware have begun to allow live and prerecorded video to be used with the same freedom that has been possible in the audio field. In fact, some of the same software that we have discussed earlier now comes with extensions for video processing and delivery. So, for example, MAX/MSP is now MAX/MSP/Jitter, with Jitter providing this extra functionality (Tools for New Media, n.d.). The fact that these extensions are part of an already well-proven programming environment, with the possibility of using the same control systems and

Figure 4. A typical analog VJ system

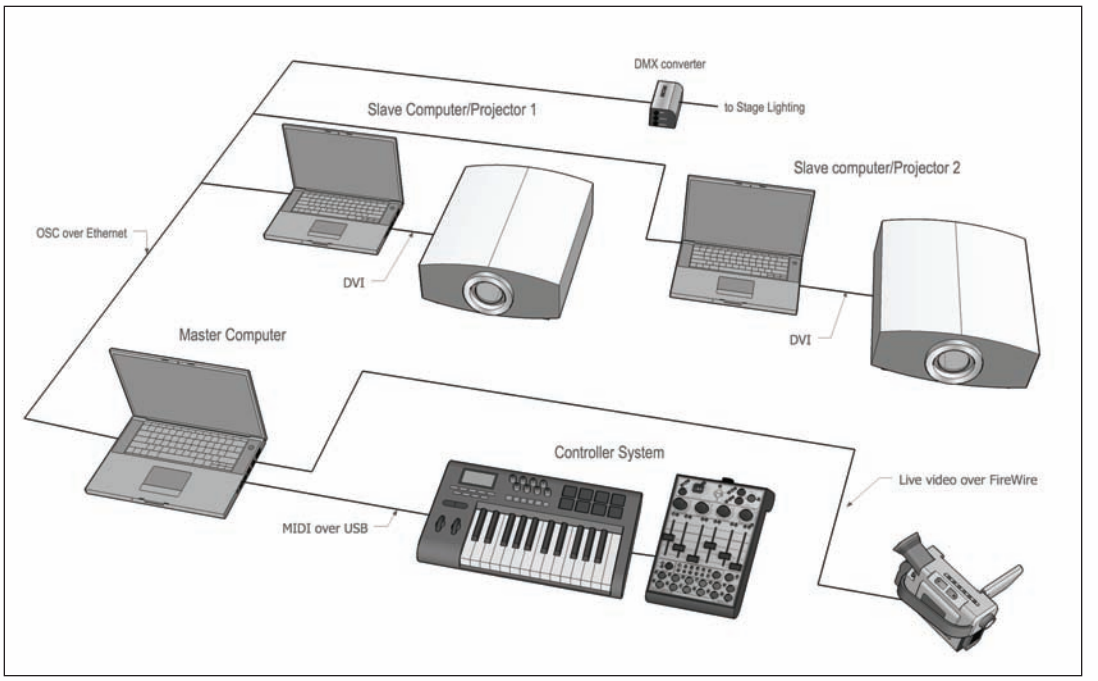


tight integration with sound, makes it immediately attractive for musical multimedia work. Other software more specifically specialised for video work, such as ArKaosVJ MIDI (Arkaos VJ 3.6 MIDI, 2006), Modul8 (Modul8, 2006), and Watchout (Dataton Watchout, n.d.), also offer similar abilities, each with its own particular emphasis.

Using the instrumental approach described earlier, we can perform video just as we can perform electronic music and, of course, VJs have been doing precisely this sort of thing for some years now, so we should expect to be able to derive systems from this field. VJing has its roots in clubbing, a world that is just as driven by the musical experience as opera, so many of the concerns outlined apply here too. What is significantly different to our concerns is a general lack of interest in narrative, which would have little place in a club anyway, so the tendency here is towards an improvisational graphic/abstract quality that suits the club experience. Much use is made of short looping sequences (in harmony with forms of dance music), with an emphasis on layering, compositing, and video effects. Larger scale media, which might carry dramatic content, are avoided. Given that VJing has always been at the forefront of technology, and has developed an aesthetic incredibly quickly, may also have a lot to do with technical limitations of systems in the past in terms of being able to deal with the very large file sizes.

The tools of the trade are usually a MIDI keyboard-triggering software on a laptop, some additional sources of video, and a vision mixer, using analog signal cabling to connect everything together. Substitute a sound mixer for the vision one and we can see the close connection to the standard electroacoustic set up. A fundamental principle of VJing is building up rich visual textures by layering smaller units. Software like Modul8 has this layering concept at the heart of its design. Here, up to five layers of video or still images are mixed and affected in real time. MIDI control allows accurate synchronised cueing of the entry and departure of these layers into the overall mix, and can control effects settings, playback speed, and layer transparency, among other things. Unfortunately, live video input from a camera does not appear to be possible. ArKaosVJ extends this by offering up to 50 layers and live input streams, and has a more intuitive MIDI interface.

Figure 5. A proposed MAX/MSP/Jitter based system—more computer/projector pairs can be added as necessary



A system like Watchout, which has its roots in corporate presentation rather than VJing, is interesting because of its high-quality support for multiple video projectors. This is achieved by using several computers networked over Ethernet. Each projector is driven by a dedicated computer, and these are all controlled from a separate production machine. The system is scaleable, can use multiple live input streams, and has some attractive features, including the ability to project over large areas using several aligned projectors that are "edge blended" to create a seamless single image, and support for advanced geometry correction to allow the use of curved screens. These make it very suitable for theatrical work, but, as yet, there is no support for MIDI or OSC control, which is a serious disadvantage, and the cueing system is not as intuitive as it could be. If we could combine Watchout's attractive features with the ease of use of something like ArKaosVJ and a custom cueing and control system, we would have something truly desirable for our purposes.

Of course, this is possible through the use of a programming environment rather than dedicated software, and MAX/MSP/Jitter provides us with precisely this. The Jitter extensions are highly optimised for video, enable any of the processes outlined, and because the audio and video system for a particular work can coexist in the same patch or in several patches running simultaneously on multiple computers linked via Ethernet and OSC, we can achieve the very high level of integration necessary for opera. Since MAX/MSP/Jitter can generate data as well as receive it, there is also the considerable advantage of being able to merge control of video and stage lighting. These obviously need to work together, and it is relatively straightforward to produce industry standard DMX protocol commands, to which any decent lighting board will respond.

It is clear to me that along the model of a VJ, we will need some form of dedicated performer to operate the "video instrument" under the direction (and so within sight) of the conductor.

Adding this workload to a pre-existing member of the production team or band is not a particularly desirable option, as they all have plenty to do already. A MIDI keyboard, combined with faders, foot pedals, and access to the computer is more than adequate as an interface if, as discussed before, the software is suitably designed, and we make sure that the computer is powerful enough to be instantaneously responsive. There ar,e of course, other possible interfaces. For example, one could be based on a percussion rather than keyboard model, but this one has precedence, and I like to think of it as a distant, highly developed offspring of the "Clavier à Lumière" Alexander Scriabin called for in his orchestral *Prometheus (The Poem of Fire)* as far back as 1911. Playing this "instrument" should feel familiar and easy to someone with experience as a VJ or electroacoustic musician, allowing a full range of performance styles from tightly specified writing through to free improvisation. It will be interesting to see how a new practice develops for this "instrument," just as MIDI keyboard technique has grown from previous forms of keyboard skills (piano and organ).

I am developing this approach for my current work, *The Girl Who Liked to be Thrown Around* (2006), my third collaboration with the writer Deepak Kalha. The piece is small in scale, takes the form of a psychological striptease, and is scored for a single woman, alto and bass flutes, and computers with two performers for sound and video, respectively. In contrast to our earlier work on *Black and Blue*, using a video performer in this has led us to think of many of the video elements in expressly musical terms-as notes to be composed and orchestrated–creating, if you will, visual melody, harmony, and counterpoint to match their counterparts in the story and music. This is not to say that the video is essentially abstract, as music is; far from it, in fact, with video having both diegetic and nondiegetic roles in the narrative. However, it does seem to promote a very nonlinear style of storytelling. This is also

Figure 6. A scene from The Girl Who Liked To Be Thrown Around*, using rear projection and a plasma screen on stage*

having interesting effects on other aspects, such as the dramaturgy and even how the words are put together, encouraging the use of multiple simultaneous layers of deconstructed material that conceal or reveal each other, depending on context.

Given this system of control for video, the directions for the performer might as well also take musical form, with events notated in a score. In the performance of opera, everyone is reading a score, from conductor to stage manager, and those who are not (the singer/actors) have memorised it. It would be simple and natural for the video performer to have a score too. It is worth remembering that the 20th century has seen considerable developments in the forms scores can take: completely standard notation, use of Lutoslawskian "mobiles," proportional notation, or the use of pure graphics provide a range of solutions to any imaginable performance situation that musicians are now quite familiar with, so this is not as limiting as it may seem.

Although it is technically possible to use computer-score-following technology to let us dispense with a performer (Philippe Manoury's *En Echo* (1993) (Manoury, 1993) for soprano and computer is an early and rather beautiful example from electroacoustic music), I completely fail to see what benefit this brings. The computer has to be operated by someone anyway, and in the context of opera, it seems reasonable to expect that person to have well-developed musical skills. More fundamentally, no matter how good the technology gets, the most interactive, intuitive thing I can think of is a person. Nothing is better at judging the energy of a scene in the moment. Human responses will make for humanity in performance, and when telling stories about people, this is vitally important.

Having said that a dedicated performer is required, putting some of the control into the hands of the singer/actors could have some very interesting results. One of the most appropriate ways of doing this would be through the use of motion tracking and gestural control. The EyesWeb software from InfoMus Lab, University of Genova (Camurri, Hashimoto, Richetti, Trocca, Suzuki, & Volpe, 2000) or Cyclops extensions to Jitter (Tools for New Media, n.d.) offer the ability to analyse incoming video in order to create control data that could be used in any number of ways, allowing the singers on stage to directly control events in the video or audio domain. The system has the advantage that it leaves the performer entirely free, there is no need to be wired up with special sensors, and we may well have live video feeds already in place.

A particularly elegant implementation of this is to bathe the stage in infrared light and then use a video camera, fitted with an infrared filter, as the input to the tracking system. This has the great advantage of working independently of any stage lighting, and the infrared light is, of course, invisible. Several actors can be tracked at once, and their interactions can be analysed to a remarkable degree, whether they are touching, moving towards or away from each other, behind or in front, and so forth. It is even possible to individually track different parts of the actor, the head, arms, and legs, and assign different triggering mechanisms to each part. As to the question of what these triggers might do, the possibilities are almost endless. We can control audio and video equally well, setting off sequences, letting imagery follow the actor around the space, defining points to cut from one scene to another, or altering the quality of the image or sound in a myriad of ways.

This can create some fascinating interactions between the live and video worlds, as has already been demonstrated in dance works by companies like Troika Ranch (Farley, 2002), but I do want to emphasise the use of the phrase *some of the control* here. Given the probably very large number of cue events an opera may contain, it would be unreasonable to expect to use this as the only means of control, and there are technical restraints on the amount of useful data that can be gener-

ated, since singers are rarely as mobile as dancers. Again, we need to be careful of overburdening our singers, and if we are striving for any form of naturalism in the acting, we will need to be subtle. But with careful planning, this could be used as an effective addition to what is already there. The great immediacy of response can create very striking effects that can be achieved in no other way, and this undoubtedly provides a very attractive way of enhancing the integration between action and video.

FUTURE TRENDS AND CONCLUSION

It is always surprising to me that opera, the form that always tried to claim the title of "total art work," has been so slow on the uptake when it comes to digital media. Undoubtedly this has much to do with the way culture of opera developed over the course of the 20th century, slowly turning it's gaze backward to the point where many contemporary composers refuse to use the term, preferring a range of inelegant alternatives (Lachenmann's "music with images,", Reich's "music video theatre," etc.). But I also believe that there has been a certain amount of waiting for the technology to become good enough to suit the form. Producing new opera is difficult and expensive, with the result that those who do it have to be pretty passionate about the form in the first place. This passion makes people very unwilling to dilute opera's natural strengths for the sake of including new media, even when there has been an understanding of, and enthusiasm for, the potential they offer. Very similar concerns apply in theatre, and here too, the amount of work of this type has been very small as a proportion of total output.

But really rather suddenly, the technology is ready, and not only ready, but easily available and relatively cheap. The rapid advance in computing power that we are experiencing will lead to big improvements in performance, ease of use, and stability very quickly, making the technology ever more attractive. There are, of course, a lot of new skills that need to be learnt, mainly in computing and programming, but precisely because these are computer based, there is instantly access to plenty of very active online communities where information and techniques are traded.

This is going to lead to an explosion of activity in this area, as people finally have the means to realise projects that have probably been in the back of their minds for a considerable amount of time. In a related sphere, the huge recent growth of VJing seems to bear this out. Eventually, we could see this becoming the dominant form for live dramatic performance-based art. The marriage of live and cinematic elements allowed by the incorporation of digital multimedia is irresistible, greatly expanding the narrative and dramatic possibilities. Even something as simple as the use of close-up, previously not possible on stage, can massively increase the power of a scene, if the acting is sufficiently good. With these elements meaningfully incorporated into the storytelling, we will be able to create sophisticated layered narratives that speak a language that modern, visually literate audiences have come to expect, and that have the power to engage and move those audiences. This need not be at the expense of the fundamentally musical nature of opera either. From this point of view, the form will not change at all. We can shape the use of multimedia to our musical requirements, rather than the other way round, so that one does not detract from the other, but rather strengthens what is already there.

Questions, of course, remain as to how successful the results of all this activity are, and what form the successful examples will take. The more work there is out there, in front of a critical public, and the greater the communication between practitioners, the better we will know the answers to this. Audiences will tell us what works and what does not. In the meantime, we need to develop effective working methods for

both creation and performance, drawing from as many fields as possible, to create a language for this new form of an old classic.

Chapter 4.11
Face Animation:
A Case Study for Multimedia Modeling and Specification Languages

Ali Arya
University of British Columbia, Canada

Babak Hamidzadeh
University of British Columbia, Canada

ABSTRACT

This chapter will discuss the multimedia modeling and specification methods, especially in the context of face animation. Personalized Face Animation is and/or can be a major user interface component in modern multimedia systems. After reviewing the related works in this area, we present the ShowFace streaming structure. This structure is based on most widely accepted industry standards in multimedia presentations like MPEG-4 and SMIL and extends them by providing a higher level Face Modeling Language (FML) for modeling and control purposes and by defining image transformations required for certain facial movements. ShowFace establishes a comprehensive framework for face animation consisting of components for parsing the input script, generating and splitting the audio and video "behaviors," creating the required images and sounds, and eventually displaying or writing the data to files. This component-based design and scripted behavior make the framework suitable for many purposes including web-based applications.

INTRODUCTION

Specifying the components of a multimedia presentation and their spatial/temporal relations are among basic tasks in multimedia systems. They are necessary when a client asks for a certain presentation to be designed, when a media player receives input to play, and even when a search is done to retrieve an existing multimedia file. In all these cases, the description of the contents can include raw multimedia data (video, audio, etc.) and textual commands and information. Such a description works as a Generalized Encoding, since it represents the multimedia content in a form not necessarily the same as the playback format,

and is usually more efficient and compact. For instance a textual description of a scene can be a very effective "encoded" version of a multimedia presentation that will be "decoded" by the media player when it recreates the scene.

Face Animation, as a special type of multimedia presentation, has been a challenging subject for many researchers. Advances in computer hardware and software, and also new web-based applications, have helped intensify these research activities, recently. Video conferencing and online services provided by human characters are good examples of the applications using face animation. Personalized Face Animation includes all the information and activities required to create a multimedia presentation resembling a specific person. The input to such a system can be a combination of audio/visual data and textual commands and descriptions. A successful face animation system needs to have efficient yet powerful solutions for providing and displaying the content, i.e., a content description format, decoding algorithms, and finally an architecture to put different components together in a flexible way.

Although new streaming technologies allow real-time download/playback of audio/video data, bandwidth limitation and it's efficient usage still are, and probably will be, major issues. This makes a textual description of multimedia presentation (e.g., facial actions) a very effective coding/compression mechanism, provided the visual effects of these actions can be recreated with a minimum acceptable quality. Based on this idea, in face animation, some researches have been done to translate certain facial actions into a predefined set of "codes." Facial Action Coding System (Ekman & Friesen, 1978) is probably the first successful attempt in this regard. More recently, MPEG-4 standard (Battista, et al., 1999) has defined Face Animation Parameters to encode low-level facial actions like jaw-down, and higher level, more complicated ones like smile.

Efficient use of bandwidth is not the only advantage of multimedia content specifications like facial action coding. In many cases, the "real" multimedia data does not exist at all and has to be created based on a description of desired actions. This leads to the whole new idea of representing the spatial and temporal relation of the facial actions. In a generalized view, such a description of facial presentation should provide a hierarchical structure with elements ranging from low-level "images," to simple "moves," to more complicated "actions," to complete "stories." We call this a Structured Content Description, which also requires means of defining capabilities, behavioural templates, dynamic contents, and event/user interaction. Needless to say, compatibility with existing multimedia and web technologies is another fundamental requirement, in this regard.

Having a powerful description and specification mechanism, also is obviously powerful in search applications that currently suffer when looking for multimedia content. MPEG-7 standard (Nack & Lindsay, 1999) is the newest arrival in the group of research projects aiming at a better multimedia retrieval mechanism.

Considering three major issues of Content Delivery, Content Creation, and Content Description, the following features can be assumed as important requirements in a multimedia presentation systems (Arya & Hamidzadeh, 2002):

1. Streaming, i.e., continuously receiving/displaying data
2. Structured Content Description, i.e., a hierarchical way to provide information about the required content from high-level scene description to low-level moves, images, and sounds
3. Content Creation (Generalized Decoding), i.e., creating the displayable content based on the input. This can be decoding a compressed image or making new content based on the provided textual description.
4. Component-based Architecture, i.e., the flexibility to rearrange the system components, and use new ones as long as a certain interface is supported.

5. Compatibility, i.e., the ability to use and work with widely accepted industry standards in multimedia systems.
6. Minimized Database of audio/visual footage.

The technological advances in multimedia systems, speech/image processing, and computer graphics, and also new applications especially in computer-based games, telecommunication, and online services, have resulted in a rapidly growing number of publications regarding these issues. These research achievements, although very successful in their objectives, mostly address a limited subset of the above requirements. A comprehensive framework for face animation is still in conceptual stages.

The *ShowFace* system, discussed later, is a step toward such a framework. It is based on a modular structure that allows multimedia streaming using existing technologies and standards like MPEG-4, Windows Media and DirectX/DirectShow (http://www.microsoft.com/windows/directx), and XML (http://www.w3.org/XML). The components independently read and parse a textual input, create audio and video data, and mix them together. Each component can be replaced and upgraded as long as it conforms to the ShowFace Application Programming Interface (SF-API). SF-API also allows other programs like web browsers to connect to ShowFace components directly or through a wrapper object called *ShowFacePlayer*. The system uses a language specifically designed for face animation applications. Face Modeling Language (FML) is an XML-based structured content description language that describes a face animation in a hierarchical way (from high-level stories to low-level moves), giving maximum flexibility to the content designers. Receiving FML scripts as input, *ShowFace* generates the required frames based on a limited number of images and a set of pre-learned transformations. This minimizes the image database and computational complexity, which are issues in existing approaches, as reviewed later.

In Section 2, some of the related works will be briefly reviewed. This includes different approaches to multimedia modeling and specification (content description in general), multimedia systems architectures to support those specification mechanisms, and eventually, content creation methods used in related multimedia systems. The basic concepts and structure of the *ShowFace* system will be discussed in Section 3 to 5. This includes the proposed Face Modeling Language (FML) and the system structure and components for parsing the input and creating the animation. Some experimental results and conclusions will be the topics of Sections 6 and 7, respectively.

RELATED WORK

Multimedia Content Description

The diverse set of works in multimedia content description involves methods for describing the components of a multimedia presentation and their spatial and temporal relations. Historically, one of the first technical achievements in this regard was related to video editing where temporal positioning of video elements is necessary. The SMPTE (Society of Motion Picture and Television Engineers) time coding (Ankeney, 1995; Little, 1994) that precisely specifies the location of audio/video events down to the frame level is base for EDL (Edit Decision List) (Ankeney, 1995; Little, 1994) that relates pieces of recorded audio/video for editing. Electronic Program Guides (EPGs) are another example of content description for movies in the form of textual information added to the multimedia stream.

More recent efforts by SMPTE are focused on Metadata Dictionary, which targets the definition of the metadata description of the content (see http://www.smpte-ra.org/mdd). These metadata can include items from title to subject and components. The concept of metadata description is a base for other similar researches like Dublin Core

(http://dublincore.org), EBU P/Meta (http://www.ebu.ch/pmc_meta.html), and TV Anytime (http://www.tv-anytime.org). Motion Picture Expert Group is also another major player in standards for multimedia content description and delivery. MPEG-4 standard, which comes after MPEG-1 and MPEG-2, is one of the first comprehensive attempts to define the multimedia stream in terms of its forming components (objects like audio, foreground figure, and background image). Users of MPEG-4 systems can use Object Content Information (OCI) to send textual information about these objects.

A more promising approach in content description is MPEG-7 standard. MPEG-7 is mainly motivated by the need for a better more powerful search mechanism for multimedia content over the Internet but can be used in a variety of other applications including multimedia authoring. The standard extends OCI and consists of a set of descriptors for multimedia features (similar to metadata in other works), schemes that show the structure of the descriptors, and an XML-based description/schema definition language.

Most of these methods are not aimed at and customized for a certain type of multimedia stream or object. This may result in a wider range of applications but limits the capabilities for some frequently used subjects like human faces. To address this issue MPEG-4 includes Face Definition Parameters (FDPs) and Face Animation Parameters (FAPs). FDPs define a face by giving measures for its major parts, as shown in Figure 1. FAPs on the other hand, encode the movements of these facial features. Together they allow a receiver system to create a face (using any graphic method) and animate based on low-level commands in FAPs. The concept of FAP can be considered a practical extension of Facial Action Coding System (FACS) used earlier to code different movements of facial features for certain expressions and actions.

After a series of efforts to model temporal events in multimedia streams (Hirzalla et al., 1995), an important progress in multimedia content description is Synchronized Multimedia Integration Language (SMIL) (Bulterman, 2001), an XML-based language designed to specify the temporal relation of the components of a multimedia presentation, especially in web applications. SMIL can be used quite suitably with MPEG-4 object-based streams.

There have also been different languages in the fields of virtual reality and computer graphics for modeling computer-generated scenes. Examples are Virtual Reality Modeling Language (VRML, http://www.vrml.org) and programming libraries like OpenGL (http://www.opengl.org).

Another important group of related works are behavioural modeling languages and tools for virtual agents. BEAT (Cassell et al., 2001) is an XML-based system, specifically designed for human animation purposes. It is a toolkit for automatically suggesting expressions and gestures, based on a given text to be spoken. BEAT uses a knowledge base and rule set and provides synchronization data for facial activities, all in XML format. This enables the system to use standard XML parsing and scripting capabilities. Although BEAT is not a general content description tool, it demonstrates some of the advantages of XML-based approaches. Other scripting and behavioural modeling languages for virtual humans are considered by other researchers as well (Funge et al., 1999; Kallmann & Thalmann, 1999; Lee et al., 1999). These languages are usually simple macros for simplifying the animation, or new languages, which are not using existing multimedia technologies. Most of the time they are not specifically designed for face animation.

Multimedia Content Creation

In addition to traditional recording, mixing, and editing techniques in the film industry, computer graphics research has been long involved in multimedia, especially in image/video creation. Two main categories can be seen in these works: 3-D

geometrical models (Blanz & Vetter, 1999; Lee et al., 1999; Pighin et al., 1998) and 2-D image-based methods (Arya & Hamidzadeh, 2002; Bregler et al., 1997; Ezzat & Poggio, 1998; Graf et al., 2000).

The former group involves describing the scene using 3-D data (as in VRML and OpenGL) and then rendering the scene (or sequence of frames) from any point of view. These techniques need usually complicated 3-D models, data and computation, but are very powerful in creating any view provided the model/data is inclusive enough. Due to the way images are generated and their inability to include all the details, most of these methods do not have a very realistic output. In the case of face animation, 3-D techniques are used by many researchers (Blanz & Vetter, 1999; Lee et al., 1999; Pighin et al., 1998). To reduce the size of required data for model generation, some approaches are proposed to create 3-D models based on a few (two orthogonal) 2-D pictures (Lee et al., 1999).

It is shown that any view of a 3-D scene can be generated from a combination of a set of 2-D views of that scene or by applying some transformations on them (Arya & Hamidzadeh, 2002; Ezzat & Poggio, 1998). This fact is base for the latter group of techniques, i.e., 2-D image-based. In a talking head application, Ezzat et al. (Ezzat & Poggio, 1998) use view morphing between pre-recorded visemes (facial views when pronouncing different phonemes) to create a video corresponding to any speech. Optical flow computation is used to find corresponding points in two images, solving the correspondence problem for morphing. Bregler et al. (1997) combine a new image with parts of existing footage (mouth and jaw) to create new talking views. Both these approaches are limited to a certain view where the recordings have been made. No transformation is proposed to make a talking view after some new movements of the head. In a more recent work based on MikeTalk, (Graf et al., 2000) recording of all visemes in a range of possible views is proposed, so after detecting the view (pose) proper visemes will be used. This way talking heads in different views can be animated but the method requires a considerably large database.

Defining general image transformations for each facial action and using facial feature points to control the mapping seem to be helpful in image-based techniques. TalkingFace (Arya & Hamidzadeh, 2002) combines optical flow and facial feature detection to overcome these issues. It can learn certain image transformations needed for talking (and potentially expressions and head movements) and apply them to any given image. Tiddeman et al. (2001) show how such image transformations can be extended to include even facial texture.

Multimedia Systems Architectures

Different architectures are proposed for multimedia systems. They try to address different aspects of multimedia, mostly streaming and playback. The main streaming systems, aimed at web-based transmission and playback, are Microsoft Windows Media, Apple QuickTime, and Real Networks RealVideo (Lawton, 2000).

Different architectures are also proposed to perform facial animation, especially as an MPEG-4 decoder/player (Pandzic, 2001). Although they try to use platform-independent and/or standard technologies (e.g., Java and VRML), they are usually limited to certain face models and lack a component-based and extensible structure and do not propose any content description mechanism more than standard MPEG-4 parameters.

STRUCTURED CONTENT DESCRIPTION IN *SHOWFACE*

Design Ideas

Describing the contents of a multimedia presentation is a basic task in multimedia systems.

It is necessary when a client asks for a certain presentation to be designed, when a media player receives input to play, and even when a search is done to retrieve an existing multimedia file. In all these cases, the description can include raw multimedia data (video, audio, etc.) and textual commands and information. Such a description works as a Generalized Encoding, since it represents the multimedia content in a form not necessarily the same as the playback format and is usually more efficient and compact. For instance a textual description of a scene can be a very effective "encoded" version of a multimedia presentation that will be "decoded" by the media player when it recreates the scene.

Although new streaming technologies allow real-time download/playback of audio/video data, bandwidth limitation and it's efficient usage still are, and probably will be, major issues. This makes a textual description of multimedia presentations (in our case facial actions) a very effective coding/compression mechanism, provided the visual effects can be recreated with minimum acceptable quality.

Efficient use of bandwidth is not the only advantage of facial action coding. In many cases, the "real" multimedia data does not exist at all and has to be created based on a description of desired actions. This leads to the whole new idea of representing the spatial and temporal relation of the facial actions. In a generalized view, such a description of facial presentation should provide a hierarchical structure with elements ranging from low-level "images," to simple "moves," to more complicated "actions," to complete "stories." We call this a Structured Content Description, which also requires means of defining capabilities, behavioural templates, dynamic contents, and event/user interaction. Needless to say, compatibility with existing multimedia and web technologies is another fundamental requirement, in this regard.

Face Modeling Language (FML) is a Structured Content Description mechanism based on eXtensible Markup Language. The main ideas behind FML are:

- Hierarchical representation of face animation
- Timeline definition of the relation between facial actions and external events
- Defining capabilities and behaviour templates
- Compatibility with MPEG-4 FAPs
- Compatibility with XML and related web technologies

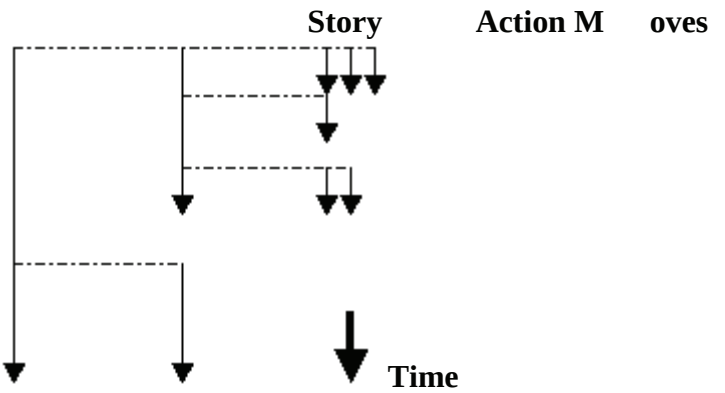
FACS and MPEG-4 FAPs provide the means of describing low-level face actions but they do not cover temporal relations and higher-level structures. Languages like SMIL do this in a general purpose form for any multimedia presentation and are not customized for specific applications like face animation. A language bringing the best of these two together, customized for face animation, seems to be an important requirement. FML is designed to do so.

Fundamental to FML is the idea of Structured Content Description. It means a hierarchical view of face animation capable of representing simple individually-meaningless moves to complicated high-level stories. This hierarchy can be thought of as consisting of the following levels (bottom-up):

- Frame, a single image showing a snapshot of the face (Naturally, may not be accompanied by speech)
- Move, a set of frames representing a linear transition between two frames (e.g., making a smile)
- Action, a "meaningful" combination of moves
- Story, a stand-alone piece of face animation

The boundaries between these levels are not rigid and well defined. Due to the complicated

Figure 1. FML timeline and temporal relation of face activities



and highly expressive nature of facial activities, a single move can make a simple yet meaningful story (e.g., an expression). The levels are basically required by the content designer in order to:

- Organize the content
- Define temporal relation between activities
- Develop behavioural templates, based on his/her presentation purposes and structure.

FML defines a timeline of events (Figure 1) including head movements, speech, and facial expressions, and their combinations. Since a face animation might be used in an interactive environment, such a timeline may be altered/determined by a user. So another functionality of FML is to allow *user interaction* and in general *event handling* (Notice that user input can be considered a special case of *external event*). This event handling may be in the form of:

- Decision Making; choosing to go through one of possible paths in the story
- Dynamic Generation; creating a new set of actions to follow

A major concern in designing FML is compatibility with existing standards and languages. Growing acceptance of MPEG-4 standard makes it necessary to design FML in a way it can be translated to/from a set of FAPs. Also, due to the similarity of concepts, it is desirable to use SMIL syntax and constructs, as much as possible.

Primary Language Constructs

FML is an XML-based language. The choice of XML as the base for FML is based on its capabilities as a markup language, growing acceptance, and available system support in different platforms. Figure 2 shows the typical structure of an FML.

An FML document consists, at higher level, of two types of elements: **model** and **story**. A **model** element is used for defining face capabilities, parameters, and initial configuration. A **story** element, on the other hand, describes the timeline of events in face animation. It is possible to have more than one of each element but due to possible sequential execution of animation in streaming applications, a **model** element affects only those parts of a document coming after it.

A face animation timeline consists of facial activities and their temporal relations. These activities are themselves sets of simple moves. The timeline is primarily created using two time container elements, **seq** and **par** representing sequential and parallel move-sets. A **story** itself

Figure 2. FML document map—Time-container and move-set will be replaced by FML time container elements and sets of possible activities, respectively

```
<fml>
    <model>        <!-- Model Info -->
         <model-info />
    </model>
    <story>        <!-- Story Timeline -->
         <action>
              <time-container>
                   <move-set>
                        < . . . >
                   <move-set>
                   < . . . >
              </time-container>
              < . . . >
         </action>
         < . . . >
    </story>
</fml>
```

Figure 3. FML primary time container

```
<seq begin="0">
    <talk begin="0">Hello World</talk>
    <hdmv begin="0" end="5" type="0" val="30" />
</seq>
<par begin="0">
    <talk begin="1">Hello World</talk>
    <exp begin="0" end="3" type="3" val="50" />
</par>
```

is a special case of sequential time container. The begin times of activities inside a **seq** and **par** are relative to previous activity and container begin time, respectively.

FML supports three basic face activities: talking, expressions, and 3-D head movements. They can be a simple move (like an expression) or more complicated (like a piece of speech). Combined in time containers, they create FML Actions. This combination can be done using nested containers, as shown in Figure 4.

FML also provides the means for creating a behavioral model for the face animation. At this time, it is limited to initialization data such as a range of possible movements and image/sound databases, and simple behavioral templates (subroutines). But, it can be extended to include behavioral rules and knowledge bases, especially for interactive applications. A typical **model** element is illustrated in Figure 5, defining a behavioral template used later in **story**.

Event Handling and Decision Making

Dynamic interactive applications require the FML document to be able to make decisions, i.e., to follow different paths based on certain events. To accomplish this **excl** time container

Figure 4. Nested time container

```
<action>
<par begin="0">
<seq begin="0">
        <talk begin="0">Hello World</talk>
   <hdmv begin="0" end="5" type="0" val="30" />
</seq>
   <exp begin="0" end="3" type="3" val="50" />
</par>
</action>
```

Figure 5. FML model and templates

```
<model>
    <img src="me.jpg" />
    <range dir="0" val="60" />
    <template name="hello" >
<seq begin="0">
    <talk begin="0">Hello</talk>
        <hdmv begin="0" end="5" dir="0" val="30" />
</seq>
    </template>
</model>
<story>
    <behavior template="hello" />
</story>
```

and **event** element are added. An event represents any external data, e.g., the value of a user selection. The new time container associates with an event and allows waiting until the event has one of the given values, then it continues with action corresponding to that value.

Compatibility

The XML-based nature of this language allows the FML documents to be embedded in web pages. Normal XML parsers can extract data and use them as input to an FML-enabled player, through simple scripting. Such a script can also use XML Document Object Model (DOM) to modify the FML document, e.g., adding certain activities based on user input. This compatibility with web browsing environments, gives another level of interactivity and dynamic operation to the FML-based system, as illustrated later in this chapter.

Another aspect of FML is its compatibility with MPEG-4 face definition/animation parameters. This has been achieved by:

- Translation of FML documents to MPEG-4 codes by the media player.
- Embedded MPEG-4 elements (**fap** element is considered to allow direct embedding of FAPs in FML document).

Figure 6. FML Decision Making and Event Handling

```
<event id="user" val="-1" />
<excl ev_id="user">
    <talk ev_val="0">Hello</talk>
    <talk ev_val="1">Bye</talk>
</excl>
```

Case Studies

Static Document

The first case is a simple FML document without any need for user interaction. There is one unique path the animation follows. The interesting point in this basic example is the use of loop structures, using **repeat** attributes included in any activity.

The **event** element specifies any external entity whose value can change. The default value for **repeat** is 1. If there is a numerical value, it will be used. Otherwise, it must be an **event** id, in which case the value of that **event** at the time of execution of related activity will be used. An FML-compatible player should provide means of setting external events values. *ShowFacePlayer* has a method called *SetFaceEvent*, which can be called by the owner of a player object to simulate external events.

Event Handling

The second example shows how to define an external event, wait for a change in its value, and perform certain activities based on the value. An external event corresponding to an interactive user selection is defined first. It is initialized to –1 that specifies an invalid value. Then, an **excl** time container, including required activities for possible user selections, is associated with the event. The **excl** element will wait for a valid value of the event. This is equivalent to a pause in face animation until a user selection is done.

It should be noted that an FML-based system usually consists of three parts:

- FML Document
- FML-compatible Player
- Owner Application

In a simple example like this, it could be easier to simply implement the "story" in the owner application and send simpler commands to a player just to create the specified content (e.g., face saying Hello). But in more complicated cases, the owner application may be unaware of desired stories or unable to implement them. In those cases, e.g., interactive environments, the owner only simulates the external parameters.

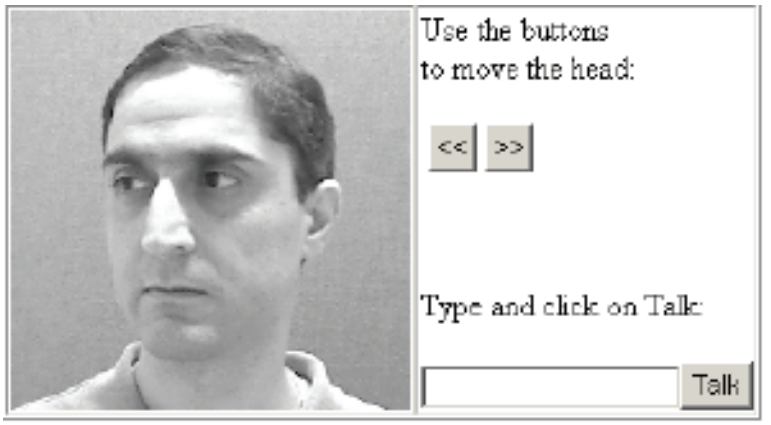
Dynamic Content Generation

The last FML example to be presented illustrates the use of XML Document Object Model (DOM)

Figure 7. Repeated activity—Using event is not necessary

```
<event id="select" val="2" />
< . . . >
<seq repeat="select">
    <talk begin="0">Hello World</talk>
<exp begin="0" end="3" type="3" val="50" />
</seq>
```

Figure 8. Dynamic FML generation



to dynamically modify the FML document and generate new animation activities.

The simplified and partial JavaScript code for the web page shown in Figure 8 looks like this:

```
function onRight()
{
    var fml = fmldoc.documentElement;
    var new=fmldoc.createElement("hdmv");
    new.setAttribute("dir","0");
    new.setAttribute("val","30");
    fml.appendChild(new);
}
```

More complicated scenarios can be considered, using this dynamic FML generation, for instance, having a form-based web page and asking for user input on a desired behavior and using templates in **model** section of FML.

CONTENT CREATION IN *SHOWFACE*

Feature-Based Image Transformation (FIX)

The FML parser component of *ShowFace* system determines the visual activities required in the face. These activities are transitions between certain face *states* like a viseme or expression. In a training phase, a set of image-based transformations is learned by the system, which can map between these face states. Transformations are found by tracking facial features when the model is performing the related transitions, and then applied to a given image, as illustrated in Figure 10. A library of transformations is created based on the following facial states:

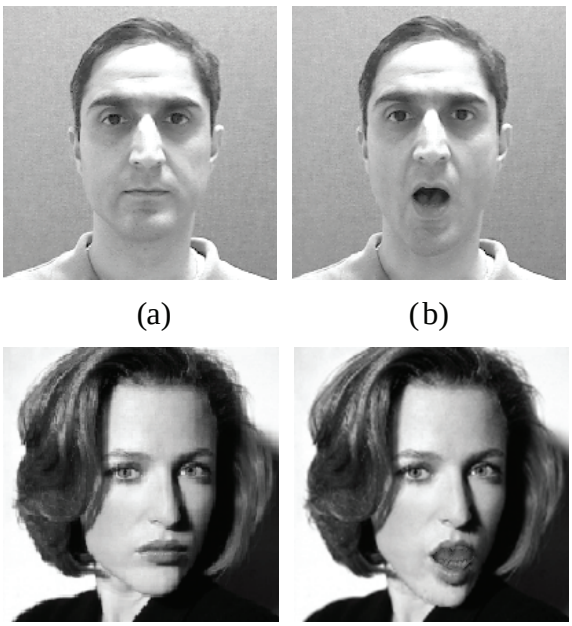
Figure 9. JavaScript code for FML event shown in Figure 6

```
function onLoad()
{
    facePlayer.ReadFML("test.fml");
    facePlayer.Run();
}

function onHelloButton()
{
    facePlayer.SetFaceEvent(
        "user", 0);
}

function onByeButton()
{
    facePlayer.SetFaceEvent(
        "user", 1);
}
```

Figure 10. Facial features and image transformations — (a) Model state 1, (b) Model state 2, (c) Target character in state 1, (d) Target character in state 2



- Visemes in full-view
- Facial expressions in full-view
- Head movements

For group 1 and 2, mappings for all the transitions between a non-talking neutral face and any group member are stored. In group 3 this is done for transitions between any two neighbouring states (Figure 11).

Each transformation is defined in the form of $T = (F,M)$ where T is the transformation, F is the feature set in the source image, and M is the mapping value for features. Source image information is saved to enable scaling and calibration, which is explained later. The feature set for each image includes face boundary, eyes and eyebrows, nose, ears, and lips. These feature lines and the facial regions created by them are shown in Figure 12.

The solid lines are feature lines surrounding feature regions, while dashed lines define face patches. The patches are defined in order to allow

Figure 11. Moving head states—The same three states exist for rotating to the left, in addition to a full-view image at the center

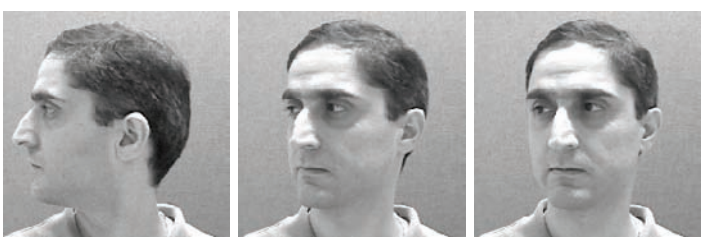


Figure 12. Facial regions are defined as areas surrounded by two facial feature lines, e.g., inside eyes or between lower lip and jaw (some face patches are removed (b) for simplicity.)

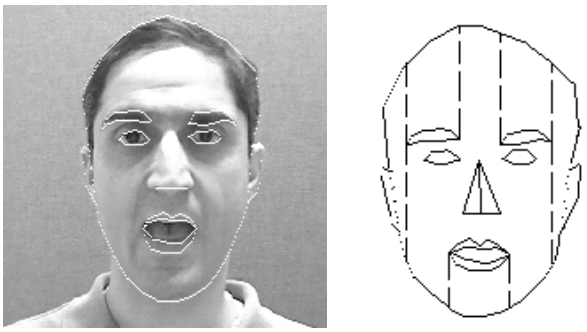

Figure 13. Feature transformation—Tij is the transformation between image-i and image-j

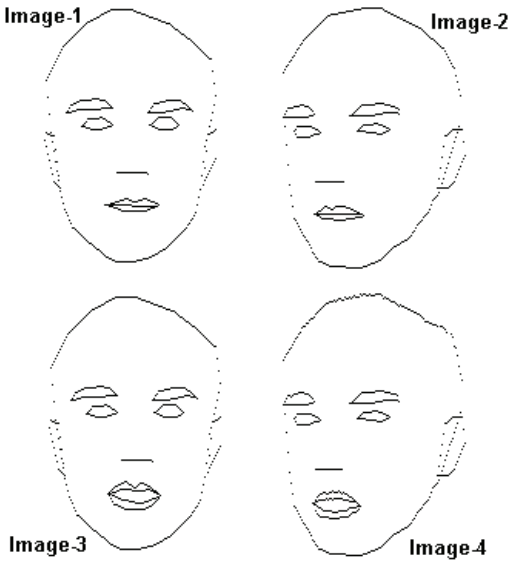


different areas of the face to be treated differently. Covisibility is the main concern when defining these face patches. Points in each patch will be mapped to points in the corresponding patch of the target image, if visible.

The transformations are done by first applying the mapping vectors for the feature points. This is shown in Figure 13. Simple transformations are those which have already been learned, e.g., T_{12} and T_{13} (assuming we only have *Image-1*). Combined transformations are necessary in cases when the target image is required to have the effect of two facial state transitions at the same time, e.g., T_{14}.

Due to the non-orthographic nature of some head movements, combined transformations involving 3-D head rotation cannot be considered a linear combination of some known transfor-

mations. Feature mapping vectors for talking and expressions (which are learned from frontal view images) need to be modified when applied to "moved" heads.

$$T_{14} = a\ T_{12} + b\ T'_{13}$$
$$T'_{13} = f_p(T_{12}, , T_{13}) = T_{24}$$

where f_p is Perspective Calibration Function and *a* and *b* are coefficients between 0 and 1 to control transition progress. T_{13} will also be scaled based on face dimensions in source/target images.

When the *Image-2* is given, i.e., the new image does not have the same orientation as the one used in learning, the required transformation is *T24, which* still needs scaling/perspective calibration based on T_{13} and T_{12}.

Facial Region Transformation

The stored transformations only show the mapping vectors for feature lines. Non-feature points are mapped by interpolating the mapping values for the feature lines surrounding their regions. This is done based on the face region to which a point belongs.

Face regions are grouped into two different categories:

- Feature islands, surrounded by one or two "inner" feature lines
- Face patches, covering the rest of the face as shown in Figure 4-b.

The mapping vector for each point inside a group-1 region is found using the following formula:

$$\mathbf{d}_{r,c} = w(\mathbf{d}_{u,c}, \mathbf{d}_{l,c})$$

where the function *w* is a weighted average with distance as the weights, *r* and *c* are row and column in the image for the given point, *u* and *l* are the row number for top and bottom feature points, and ***d*** is the mapping vector.

Face patches are defined based on covisibility, i.e., their points are most likely to be seen together. Defining the patches is necessary in order to preserve the geometric validity of the transformation. The mapping vector of each point in a patch is the weighted average of mapping of all the patch corners. Extra checking is performed to make sure a point inside a patch will be mapped to another point in a corresponding patch of the target image.

Sample Images

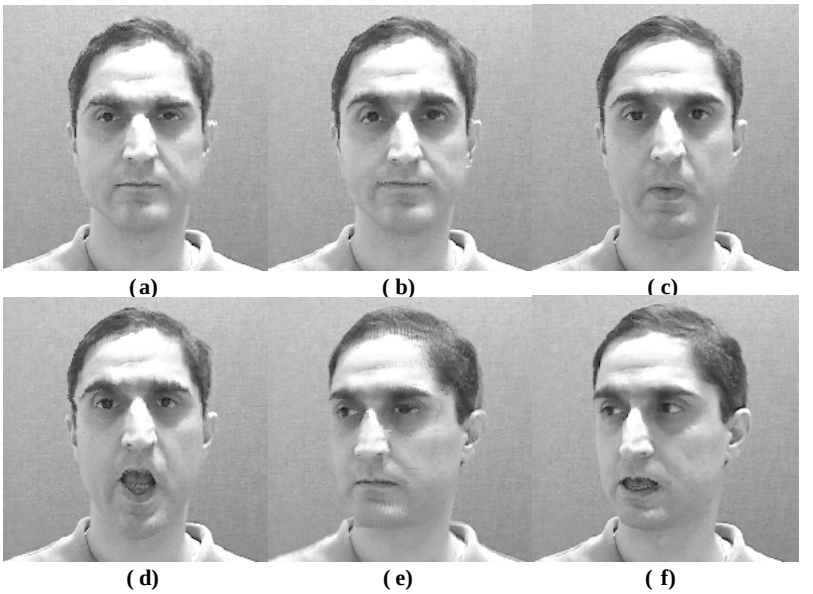
Figure 14 shows some sample outputs of the image transformations.

Speech Synthesis

To achieve the best quality with minimum database requirements, *ShowFace* uses a concatenative approach to speech synthesis. Diphones (the transitions between the steady-state of a phoneme to the steady-state of another) are used as the basis of this approach. An off-line diphone-extraction tool is designed to create a database of diphones from existing audio footage. This database is normalized for power and pitch to provide a smooth initial set. The diphones are then dynamically connected based on the phoneme list of a given text to be spoken.

An FFT-based comparison of diphones finds the best connection point for two diphones at run time. This results in a dynamic time length calculation for diphones and words, which will then be used to find the necessary duration of the corresponding visual transitions and the number of frames to be generated, in order to achieve a lip-synchronized audio-visual stream.

Figure 14. Transformed faces—Mapped from 7-a: (a) frown, (b) smile, (c and d) visemes for sounds "oo" and "a" in "root" and "talk", (e) rotate to right, and (f) non-frontal talking



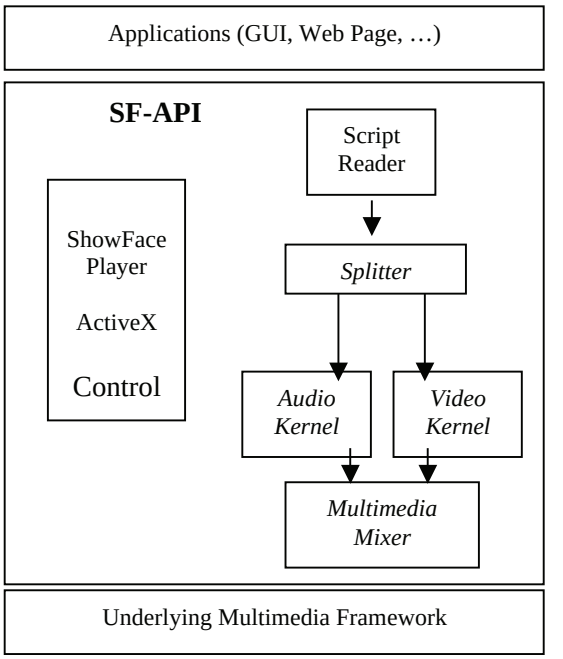
SHOWFACE FRAMEWORK

System Architecture

The basic structure of the *ShowFace* system is illustrated in Figure 15. Five major parts of this system are:

- Script Reader, to receive an FML script from a disk file, an Internet address, or any text stream provider
- Script Parser, to interpret the FML script and create separate intermediate audio and video descriptions (e.g., words and viseme identifiers)
- Video Kernel, to generate the required image frames
- Audio Kernel, to generate the required speech
- Multimedia Mixer, to synchronize audio and video streams

Figure 15. Component-Based ShowFace System Structure



ShowFace relies on the underlying multimedia technology for audio and video display. The system components interact with each other using the ShowFace Application Programming Interface, SF-API, a set of interfaces exposed by the components and utility functions provided by the *ShowFace* run-time environment. User applications can access system components through SF-API, or use a wrapper object called *ShowFacePlayer,* which exposes the main functionality of the system, and hides programming details.

ShowFace system is designed and implemented with the concept of openness in mind. By that we mean the ability to use and connect to existing standard components and the independent upgrade of the system modules. To make most use of existing technologies, *ShowFace* components are implemented as Microsoft DirectShow filters.

DirectShow is a multimedia streaming framework, which allows different media processing to be done by independent objects called *filters,* which can be connected using standard Component Object Model (COM) interfaces. DirectShow will be installed as part of many application programs like browsers and games and comes with a set of filters like audio and video decoders and renderers. This allows *ShowFace* objects to access these filters easily and rely on multimedia streaming services provided by DirectShow, e.g., receiving data from a URL reader or MPEG-4 decoder and sending data to a video player or file writer.

The *ShowFacePlayer* wrapper object is implemented as an ActiveX control, which can be easily used in web pages and other client applications. An off-line tool, *ShowFace Studio,* is also developed to assist in detecting the features, creating the maps and recording the FML scripts. Some samples of transformed faces are shown in Figure 4.

CONCLUDING REMARKS

Reviewing the most important works in the area of multimedia specification and presentation, it's been shown that a comprehensive framework for face animation is a requirement, which has not been met. Such a framework needs to provide:

- a structured content description mechanism,
- an open modular architecture covering aspects from getting input in standard forms to generating audio/video data on demand,
- efficient algorithms for generating multimedia with minimum use of existing footage and computational complexity.

An approach to such a framework, ShowFace System, is proposed. Unlike most of the existing systems, ShowFace is not limited to an off-line application or a media player object, but provides a complete and flexible architecture. The component-based architecture uses standard interfaces to interact internally and also with other objects provided by an underlying platform, making maximum use of existing technologies like MPEG-4, XML, and DirectX. These components can be used separately or in a combination controlled by the animation application.

An XML-based Face Modeling Language (FML) is designed to describe the desired sequence of actions in form of a scenario. FML allows event handling and a sequential or simultaneous combination of supported face states and will be parsed to a set of MPEG-4 compatible face actions. The Main contributions of FML are its hierarchical structure, flexibility for static and dynamic scenarios, and dedication to face animation. Compatibility with MPEG-4 and the use of XML as a base are also among the important features in the language. Future extensions to FML can include more complicated behaviour modeling and better coupling with MPEG-4 streams.

The image-based transformations used in the video kernel are shown to be successful in creating a variety of facial states based on a minimum input of images. Unlike 3-D approaches, these transformations do not need complicated modeling and computations. On the other hand, compared

to usual 2-D approaches, they do not use a huge database of images. They can be extended to include facial textures for better results and the system allows even a complete change of image generation methods (e.g., using a 3-D model), as long as the interfaces are supported.

Better feature detection is a main objective of our future work, since any error in detecting a feature point can directly result in a wrong transformation vector. This effect can be seen in cases like eyebrows where detecting the exact corresponding points between a pair of learning images is not easy. As a result, the learned transformation may include additive random errors, which cause non-smooth eyebrow lines in transformed feature sets and images.

A combination of pre-learned transformations is used to create more complicated facial states. As discussed, due to the perspective nature of head movements, this may not be a linear combination. Methods for shrinking/stretching the mapping vectors as a function of 3-D head rotation are being studied and tested. Another approach can be defining the mapping vectors in terms of relative position to other points rather than numeric values. These relational descriptions may be invariant with respect to rotations.

Chapter 4.12
Multimedia Computing Environment for Telemedical Applications

V. K. Murthy
University of New South Wales, Australia

E.V. Krishnamurthy
Australian National University, Australia

INTRODUCTION

Telemedicine (in short, e-medicine) is a means of delivering medical services to any place, no matter how remote, thereby removing the limitations of space and time that exists in today's health-care settings. Computers are indispensable in telemedicine, since they provide for efficient, relevant data gathering for large-scale applications. Besides providing immediate feedback of results to patients and doctors, they also can compare past patient records and evaluate relative improvement or deterioration. Further, they are readily available at any time, fatigue-free and can be more objective.

Five important application areas of telemedicine are:

1. Lifetime health care;
2. Personalized health information;
3. Tele-consultation;
4. Continuing Medical education; and
5. Context-aware Health monitoring.

For example, computers provide for multimedia imaging: ultra sound, digital X-rays, 3D spiral Cat Scanner, magnetic resonance imaging, PET scanning, and so forth, and can fuse them into a single multi-purpose image using fusion software. Adding mobility to computers enhances their role in telemedical applications considerably, especially at times of emergency since the patients, doctors, the data collecting and retrieval machines, as well as their communication links can always be on the move. Very simple, inexpensive mobile communication and computing

devices can be of great help in telemedicine, as explained in the following:

- ***Low Cost Radio:*** Even the simplest of mobile devices, such as a low power radio that can transmit messages to a home computer from which medical data can be sent through telephone line and the Internet can be of great value in saving lives (Wilson et al., 2000).
- ***Personal Digital Assistants (PDA):*** The simplest of the computers, such as palmtops and PDA can assist the doctors for instant nomadic information sharing, and look for diagnosis of different diseases and treatment. PDA can help the doctors to figure out drug interactions, storing summaries of sick patients and their drug list. Further, PDA can provide for downloading suitable programs from the Web, and can be programmed for alert, sending and receiving email, jotting down pertinent points, and for storing immediately needed clinical results to carry out ward rounds. Also a hand held system can provide context-awareness to support intensive and distributed information management within a hospital setting (Munoz et al., 2003).
- ***Internet:*** The Internet is an important tool for medical professionals and will completely change the manner in which medical consultations are provided (Coiera, 1997); for further details on telehealth and telemedicine practice and their real life implementation issues, refer to Orlov and Grigoriev (2003), Jennett and Anddruchuk (2001), and Suleiman (2001).

For minor ailments, Internet-based consultations to doctors can provide prescriptions for medical/pathological examinations by laboratories. The results are then posted in the Internet for subsequent reading of the results by the concerned doctors who can prescribe medicines that can be posted on the Internet. This prescription can then be handled by a pharmacy to dispense the medicines to the concerned individual. Kim and Hwang (2001) have proposed a password controlled Internet-based medical system that brings in a variety of services to doctors, patients, pharmacists and health-care professionals. It allows people to receive medical examinations and medical advice.

BACKGROUND: TELEMEDICAL INFORMATION SERVICES

The first step in telemedicine is the telemedical diagnosis (or telediagnosis) based on information obtainable from medical images, blood, urine and other pathological test reports. Usually, for diagnostic purposes, the doctor sends a patient for such examinations. The laboratory assistant takes the required X-ray or ultrasound images or carries out pathological tests and passes these images (or readings) on to a radiologist/pathologist who then makes analysis and sends a report to a doctor. These manual actions are totally sequential and slow. This whole procedure can be made cooperative and faster, if the images and data are stored in a database and these can be simultaneously retrieved by specialists in their offices or homes to make a cooperative diagnosis (Alfano, 1997; Coiera, 1997; Ganapathy, 2001; Gomez et al., 1997; Jameson et al., 1996; Kleinholz et al., 1994; Lauterbach et al., 1997).

Principal Aims

The principal aims of e-medical informatics are to:

(i) provide online services of patient records (medical and pathological databases) to medical practitioners and radiologists;
(ii) provide primary specialist diagnosis, offer second opinion, provide pre- and post treatment advice through email;

(iii) reduce the cost of imaging equipment, delay, and increase the speed and volume of diagnosis;
(iv) aid cooperative diagnosis and provide assistance for remote surgery;
(v) provide student /resident education;
(vi) reduce professional isolation, increase collaboration; and
(vii) provide home-care.

Advantages

E-medicine offers the following advantages:

(i) Provides health care to under-served and isolated areas so that we can make a better allocation and utilisation of health resources.
(ii) Since communication cost is much cheaper than the transportation cost, patients in remote areas can outreach physicians quickly.
(iii) Increases the speed of diagnosis and treatment especially when used for teleradiology, cardiology, psychiatry.
(iv) Allows access to specialty care using time-oriented clinical data.
(v) Real-time monitoring of public health databases to prepare and respond during epidemics, biological and chemical terrorism.
(vi) Internet can provide the following support:
    a. Health information;
    b. Administrative infrastructure;
    c. Online health records;
    d. Pharmaceutical information and sales outlets; and
    e. Online training for telemedical professionals.

Prerequisites

The pre-requisites for a successful implementation of a telemedical system are:

- *Infrastructure:* A suitable infrastructure of health care providers, doctors, engineers, computing specialists, communication engineers, information technology professionals and medical statisticians to analyse outcomes and suitable outreach clinics with telemedical facilities.
- *Communication Network:* Reliable, inexpensive and readily accessible communication network from outreach clinics to hospitals, doctors and patients and pathological laboratories.
- *Low-cost Computers:* Suitable low-cost hardware-software and a good communication bandwidth to transmit medical data in different modes; for example, radiological images, video images of signals and text. While using wired in or wireless mobile devices and monitors, the effect of electromagnetic interference (EMI) and radio frequency interference (RFI) on data collection and transmission, and the side-effects on patients, both physiological and psychological aspects, have to be taken care of so that improper diagnosis does not result.
- *Training Facility:* Training of personnel to provide proper maintenance of equipment and safety standards to patients.
- *Security, Reliability, Efficiency:* Reliability, Efficiency, Security, Privacy and Confidentiality in handling, storing and communicating patient information.

Economic Necessity

In densely-populated countries (e.g., India), the rate of growth in hospital beds to cope up with the increasing population is economically unsustain-

able and technically not viable, since the number of medical specialists also cannot grow to meet this demand (Ganapathy, 2001). The use of telemedicine avoids unnecessary strain involved in travel and associated expenses, provide immediate attention and care, can avoid hospitalization, and allow the patients to stay home enjoying family support. Chan et al. (2000) describe a real-time tertiary foetal ultrasound telemedical consultation system using standard integrated system digital network (ISDN) that operates in Queensland, Australia. This consultation system has gained acceptance from the clinicians and patients. Aging population and rising health costs have created the need to care for more patients in their own homes. Hospitals without walls (e-hospitals or virtual hospitals) provide for continuous monitoring of patients in certain diagnostic categories. Wilson et al. (2000) describe how to build such "hospital without walls". This system uses a miniature, wearable low power radio to transmit vital and activity information to a home computer, from which data is sent by telephone line and the Internet to the concerned doctors. Thus, telemedicine and telediagnosis are economic necessities for both the developing and the developed world.

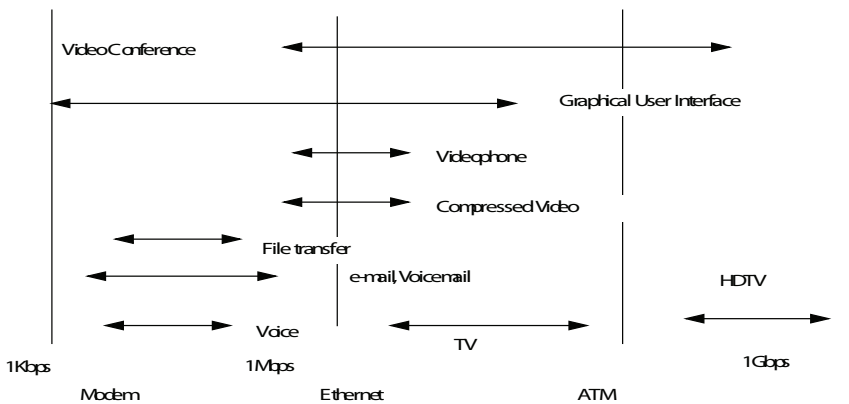
MAIN THRUST OF THE ARTICLE

The main thrust of this chapter is to describe the multimedia telediagnostic environment (MMTE), its features, and some practical MMTE systems that are currently operational.

MULTIMEDIA TELEDIAGNOSTIC ENVIRONMENT

A Mobile Multimedia Telediagnostic Environment (MMTE) permits users to work remotely on common shared resources and applications and simultaneously communicate both visually and through audio. Such an environment becomes more flexible and useful if it can work in a wireless and wired-in (integrated) environment so that the services can be provided for mobile hosts. Here, the users have interfaces of PDA or laptops interacting remotely. In this application, we need cooperation among the participants through special communication tools for conversation (Roth, 2001) and E-pointing (MacKenzie & Jusoh, 2001). The conversation can be of conference type where two or more participants are involved. The e-pointers aid each participant to point out a particular segment of an image or a

Figure 1. Bandwidth (log scale) requirements



video image of a signal so that each of the other participants can visualize the movements of the remote pointer. Also in telesurgery (e-surgery) where two or more operating rooms are connected by a network, live video signals may required to be transferred to other remote locations from endo-camera (camera for photographing internal organs) and operating room camera to other remote locations for consultancy. This would allow surgeons not only to see but also visualize surgical instrument movements with 3-D models in real time during the surgery.

Pre-requisites for the Deployment of MMTE

Reliable Communication Network and Equipment

A reliable multimedia communication network that links the remote centres with hospitals is essential. The delivery of multimedia content in a timely fashion is very important. Internet provides a uniform communication medium to link users together to access or deliver multimedia information.

- Communication Bandwidth Requirements: Text requires the lowest bandwidth, while audio and video data and signals require significant increase in bandwidth. Specification of bandwidth to be used and compression techniques used are to be laid down so that the data and images that are transmitted are of diagnostic quality.
- Bandwidth Management: Bandwidth determines the information capacity of a network per unit of time. Wireless networks deliver lower bandwidth than wired network. Hence software techniques based on compression should be used. Also scheduling communication intelligently can save bandwidth. For use in telemedicine the techniques should be extremely reliable. Current cutting edge technologies are yet to develop. Bandwidth requirements along with applications are given in (approximate) logarithmic scale in Figure 1.

Three common technologies used are: (bps = bits per second; K= Kilo; M= Mega; G = Giga)

Dial up mode: Rate 28.8Kbps
T1: 1.544 Mbps; DS3: 45 Mbps

For example, standard X-ray transmission takes 30 minutes in dial-up mode, 30 seconds in T1 mode and 1 second in DS3. It is obvious that the cost goes up, as we want to increase the bandwidth to communicate voice, data and pictures. DS3 is a dedicated, private line service designed for point to point communication. This service uses fibre optic cable. One can have the option of tiered DS3 service from lower to higher bandwidth from 5 Mbps to 45 Mbps depending upon cost considerations and transmission requirements.

- Choice of Multimedia Hardware: We need a proper choice of graphics and audio equipment for quality images and audio for diagnosis.

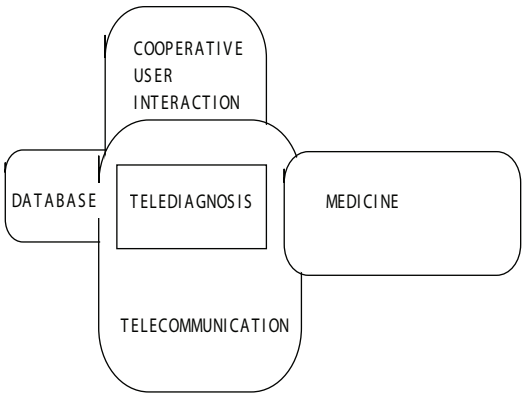
FEATURES OF A TELEDIAGNOSTIC ENVIRONMENT

A typical cooperative telediagnostic (e-diagnostic) environment is shown in Figure 2. It consists of databases containing medical/pathological image and textual information, cooperative interaction facility, and telecommunication. Typically, its characteristics are:

Remoteness of Users

Users work remotely on common shared resources and applications and simultaneously communicate both visually and through audio. This environment becomes more flexible and useful, if it can

Figure 2. Cooperative diagnostic mobile environment



work in an integrated (wireless and wired-in) environment so that the services can be provided for mobile hosts.

Cooperation

Many e-medicine applications require doctors, specialists and health-record officials to cooperate and discuss for particular medical treatment. Cooperation among the participants requires special communication tools for conversation, e-pointing, e-surgery.

E-pointing Facility

E-pointing is the act of moving an on-screen tracking symbol such as a cursor, by manipulating the input device. The interactive e-pointers (MacKenzie & Jusoh, 2001) aid each participant to point out a particular segment of an image or a video image of a signal so that each of the other participants can visualize the movements of the remote pointer and discuss any abnormality for diagnostic purposes.

Facility for Internet Link

Also users can remotely access worldwide knowledge bases/databases, download files from the Internet and browse the World Wide Web using portable and mobile devices such as laptops, palmtops and PDA.

Interoperability

Software interoperability is a key requirement in telemedicine, since different modalities of patient records are used on different platforms.

- **Security Requirements**: Security of patient data during storage and transmission are vital to safeguard confidentiality and privacy of patient information. Biometric authentication (Nanavati et al., 2002) could be an answer in dealing with patient information. Health Insurance Portability and Accountability Act (HIPAA) has devised certain security measures to handle telemedical information, see Web document of HIPAA.

FUTURE TRENDS: SOME PRACTICAL MMTE SYSTEMS

Context-Aware Mobile Communicaton in Hospitals

Handheld systems can provide for context-awareness in hospitals. This can provide speedy collaboration among doctors to deal with time sensitive cases, for example, delivery, heart attacks, accidents (Munoz et al., 2003).

Presently, portable and mobile devices such as laptops and personal digital assistants (PDA) are useful for remotely accessing resources in an efficient and reliable manner and for reliable telediagnosis (Lauterbach et al., 1997; Roth, 2001). For instance, information sharing among doctors through handheld appliances are useful for transmitting small amounts of data, such as heart rate, blood pressure and other simple monitoring devices. Typical datatypes for current handheld

appliances are: text, data entries, numbers, tables. None of the applications described previously can deal with multimedia data, such as audio, video which require considerable bandwidth, sufficient output devices, and a very powerful battery. Presently, multimedia data are not yet suitable for handheld appliances; they need to undergo major developments (Roth, 2001). Currently available tools, such as GyroPoint and RemotePoint (MacKenzie & Jusoh, 2001), lack accuracy and speed. The telepointer technology has yet to mature to provide reliable service for e-medicine and e-surgery. Along with the use of virtual reality, the pointer technology can be useful in teaching surgery, and for trial-error planning of operations.

Image-Guided Telemedical System

Lee (2001) describes a Java-applet based image-guided telemedicine system via the Internet for visual diagnosis of breast cancer. This system automatically indexes objects based on shape and groups them into a set of clusters. Any doctor with Internet access can use this system to analyze an image and can query about its features and obtain a satisfactory performance (http://dollar.biz.uiowa.edu/~kelly/telemedicine.html).

Software Agent based Telemedical Systems

Software agents, which are personalized, continuously running and semi-autonomous objects, can play an important role in cooperative telemedicine. Such agents can be programmed for supporting medical diagnostic intelligence and keep a watchful eye to discover patterns and react to pattern changes that usually occur in epidemics, biological and chemical terrorism.

For example, diabetes is a chronic disease with a sustained elevated glucose level. The diabetics need to be injected insulin to control the glucose level. This is quite a tedious book-keeping procedure. Real-time monitoring using agents and immediate therapy can save a life.

Also agents can help in the appropriate choice of doctors, allocation of hospitals and beds for patients. Ganguly and Ray (2000) describe a methodology for the development of software agent-based interoperable telemedicine system. This system has been illustrated using tele-electrocardiography application. Also recently, a practical agent-based approach to telemedicine has been suggested by Tian and Tianfield (2003). For medical education, this will be a very useful tool. The Foundation for Intelligent Physical Agent Architecture (FIPA, http://www.fipa.org) aims to improve agent interoperability by providing standards for protocols and languages. Also the Java 2 MicroEdition (J2ME) is targeted at PDA. These developments will provide an agent execution environment in PDA.

CONCLUSION

Cooperative telemedical informatics will have a direct impact on the rapidly changing scene of information and communication technology (including advanced communication systems) and will provide for greater interaction among doctors and radiologists and health-care professionals to integrate information quickly, efficiently and make effective decisions at all levels. Virtual e-hospital or hospital without walls will be a reality soon providing great benefit to the society.

KEY TERMS

Bandwidth Management: Determines the information capacity of a network per unit of time. Wireless networks deliver lower bandwidth than wired network. The choice of appropriate bandwidth for efficient and cost effective transmission of voice, data and pictures is called bandwidth management.

Confidentiality and Security in Telemedicine: Security and confidentiality of patient data during storage and transmission are vital to safeguard confidentiality and privacy of patient information. Biometric authentication, could be an answer in dealing with patient information. HIPAA (Health Insurance Portability and Accountability Act) has devised certain security measures to handle telemedical information (http://www.hipaadivsory.comregs/securityoverview.htm)

Multimedia Telediagnostic Environment (MMTE): Permits users to work remotely on common shared resources and applications and simultaneously communicate both visually and through audio.

Software Agents: Personalized, continuously running and semi-autonomous objects. They can play important role in cooperative telemedicine. Such agents can be programmed for supporting medical diagnostic intelligence and keep a watchful eye to discover patterns and react to pattern changes that usually occur in epidemics, biological and chemical terrorism

Software Interoperability: Permits different software to run on different platforms with different operating systems.

Telemedicine (E-Medicine): A means of delivering medical services to any place, no matter how remote, thereby removing the limitations of space and time that exists in today's health-care settings.

Telepointers: The act of moving an on-screen tracking symbol, such as a cursor, by manipulating the input device from a remote site.

Virtual E-Hospital (or Hospital Without Walls): A telemedical facility that provides continuous monitoring of patients staying in their homes and enjoying family support and creates a psychological satisfaction to the patients that they are receiving immediate attention and care as if they are in a real hospital.

Chapter 4.13
Interactive Multimedia and AIDS Prevention:
A Case Study

José L. Rodríguez Illera
University of Barcelona, Spain

ABSTRACT

Using multimedia applications to inform or to train is very different than using them for changing attitudes. The documented and discussed project started with the perspective that a large proportion of young people, despite knowing how AIDS might be contracted, still adopt risk behaviors. A multimedia role play application was designed to include both information and game layers. The game introduces complex situations using video stories, and then lets the users construct different narratives by choosing between behavior alternatives. The result of each narrative is related to contracting the disease or not. A discussion about role playing games follows, on the limits of this approach, as well as the kind of interactivity and the forms of delayed feedback given.

INTRODUCTION

This chapter provides a detailed description of a multimedia AIDS prevention project undertaken jointly by research teams in Italy and Spain. The project, "AIDS: Interactive Situations," was funded by the European Union and resulted in the setting up of a Web site and the production of a hybrid CD-ROM, of which more than 40,000 copies were distributed, through both public and private channels, in the two participating countries between 1999 and 2000. The chapter is divided in five parts: a description of the project rationale and an outlining of its objectives; a description of the project's contents; a description of the multimedia technology used and the interactive approach incorporated; a discussion of the project; and conclusions reached.

PROJECT RATIONALE AND OBJECTIVES

AIDS prevention is a constant concern of the education and health authorities. Prevention campaigns are frequently mounted, and wide use of the mass media is made in conveying the message. However, interactive media have only rarely been used for this purpose.

At the start of the 1990s, the only software available were HyperCard stacks and similar programs containing AIDS fact files and information about the ways in which the disease might be contracted, and a number of simulation programs based on system dynamics models that demonstrated the evolution of the disease at a time when it was thought to be fatal in a period between 10 and 15 years (González, 1995). Multimedia programs were later developed, but their primary purpose was as a source of medical information (AIDS 2000 Foundation). Other programs included a computer game that allowed the study of epidemics throughout history (Fundació LaCaixa, 1995).

In developing this project, "AIDS: Interactive Situations," the aim was to provide a different focus. In fact, by the mid-1990s, most adolescents (here, and throughout the chapter we refer solely to adolescents in the Western world) had a good grounding in the basics of AIDS prevention, thanks in large measure to the prevention campaigns. Yet, despite knowing how the disease might be contracted, a large proportion of adolescents still adopted risk behaviors. This discrepancy between the information received and the attitudes that guide their behavior is a constant feature among adolescents.

The main aim of this project was, therefore, to focus on the subjects' perceptions of risk situations and the consequences of their behaviors. The other objective of the project involved the provision of decision-making techniques in situations of risk, always exemplified by the failure to use a condom in heterosexual relations.

CONTENTS AND EDUCATIONAL DESIGN

The results of the project's psychological and educational analyses indicated the type of contents and transformations required. We concluded that the best approach was to include a purely informative content, offering information about the disease and the ways in which it might be transmitted, plus information describing its psychological and social features. This information serves as a ready reference for schools and can also be consulted on an individual basis. As we shall see later, it serves an additional function, one that we consider to be of considerable importance. This information "layer" is included in a straightforward hypertext format and aims above all to be user friendly. It also incorporates a number of further multimedia tools, including a map of AIDS information centers. The contents are organized in five sections:

1. *The disease*: This section contains information about HIV, how the virus is produced, how it acts on the organism, etc.
2. *Prevention*: This section allows the user to acquire information about how to prevent AIDS, which sexual practices involve the greatest and least risk, and how to use male and female condoms.
3. *The AIDS test*: This section explains when one should take the AIDS test, how to go about taking it, and how to interpret the results.
4. *Ideas and behaviors*: This section focuses on techniques to become more assertive, including negotiation and dialogue at times of conflict, understanding oneself better, etc.
5. *To find out more*: This section lists books, songs, films, and Internet Web sites that contain information about AIDS.

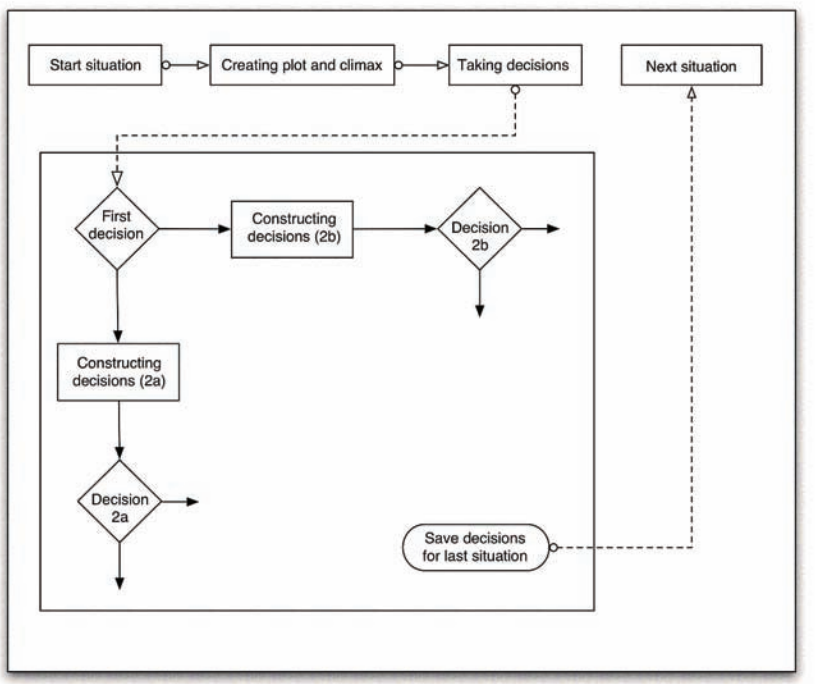
The main content, however, comprises an interactive role-playing game. This format was selected as it was considered the best way to meet the aims of changing attitudes and of simulating the negotiation and dialogue that occurs in situations of risk. In Tonks' (1996) review of techniques for providing information about AIDS and changing attitudes about the disease, role-playing games

appear as the basic tool, although not as part of a multimedia application—which in Tonk's review are considered only in their audiovisual format. Role-playing games offer many advantages, above all the possibility of testing the skills that are being learned or developed in a safe environment. Furthermore, role play allows great flexibility in terms of content, and it is typically used without any multimedia components.

The role play is based around the metaphor of a summer trip taken by a group of friends around Europe. In this group, there is a couple in a steady relationship who have to deal with a number of different situations. The program user has to choose at the outset whether to be the male or female character and has to behave in accordance with this choice throughout the journey, as the content varies depending on the role that has been selected. The choice of character does not depend on the sex of the player, given that the game can be played in a group or as part of a class activity within a school, but it conditions the way in which the game develops, presenting a particular point of view in each situation. In fact, we believe that this initial choice constitutes the user's main point of identification with the game, because the player then has to interact in the program as if he or she were one of the characters and to adopt what they consider to be the character's point of view.

The role play is organized around six situations: the first acts as an introduction, the next four present risk situations, and the last tells the user the results of the decisions he or she has taken. Each of the four risk situations is organized in a similar manner: first, a narrative section is presented in which a complex situation is introduced, followed by an interactive section in which decisions are made. This common format ensures that the main story line in the game is easily followed, as the metaphoric journey is always brought to a halt by a situation that is presented in a similar way, and after the user has made the required decisions, he or she can continue on the journey, whatever happens. Decisions have to be taken: the user

Figure 1. Flow diagram of the game



cannot proceed with the game if decisions are not made, and the user's results are stored and not shown until the end of the game. Figure 1 shows the overall organization of the game, although the decision-making tree diagram only shows the first two levels.

Each situation involves the use of condoms in heterosexual relationships, but each emphasizes a different ability that we wish to strengthen within the general framework of negotiating condom use: the first is the ability to stand by one's opinions in a dialogue with one's partner, the second is resisting group pressure, the third includes the situations that arise when changing partners, and the fourth includes the decisions that are made under the influence of alcohol and drugs. In addition to these main abilities, each situation presents a considerable amount of informative material contained within the dialogues, both in the video and in the decision-making section. This information, at times debatable as it is presented as the opinion of one of the characters, is contained within the project's hypertext.

The choice of content is important in several respects: first because of the abilities described above, second because of the physical settings in which the story unfolds, third because of the overall credibility of the situations, and fourth because of the language presented within the dialogues.

The Educational Design

Given the complexity of the psychological and pedagogical aspects of the project, it is extremely difficult to find one conceptual framework that can support its educational design. In general, educational multimedia applications tend to use a cognitive theoretical framework or, on occasion, a constructivist one (Duffy et al., 1992; Duffy & Cunningham, 1996). However, in most cases, applications are not designed on the basis of a single theoretical viewpoint but use several to try to resolve a specific instructional problem.

The main feature that distinguishes multimedia projects such as the present one from approaches that seek to automate instructional design is that they are driven both by the problem and by the theoretical frameworks of the designers. That is, inside specific theoretical orientations, instructional and learning strategies are sought that make it possible to resolve the problem—a *bricolage*-type activity. Determining what is most important is only possible if the characteristics of each particular case are taken into account.

For the most part, multimedia role plays such as "AIDS: Interactive Situations" use general educational principles of constructivist type, albeit in combination (*bricolage*) with other related approaches. These principles have been studied on many occasions, though the analysis has been largely generic and has not been applied to specific cases of educational multimedia applications. We can speak of three fundamental principles that guide the educational design:

1. The individual construction of meaning
2. The situated character of cognition and learning
3. The play environment as a construction of the player's identity

The Individual Construction of Meaning

This is the fundamental principle of constructivist approaches and is what distinguishes them from teaching models that are based on the transmission of knowledge. Knowledge is constructed by integrating meaning (or sense) into preexisting, personal structures.

In our case, the content is structured according to the model of interaction discussed above, that is, by allowing the pupils to select their own paths by means of the choices that they make. Participants construct their own path, or narrative, by choosing from the many alternatives that the game allows. In contrast, many of the programs that merely provide information on AIDS, without

offering other activities (interesting as they are in their own right) can be considered as merely transmitting a particular type of knowledge (medical, psychological, or social). The construction of meaning requires the involvement of the learner so that the new knowledge is integrated and internalized, even in the case of a simple activity such as deciding how a story is going to develop.

The Situated Character of Cognition and Learning

The concept of "situated learning and cognition" (Lave, 1988, 1990) which is a radical critique of the cognitivist vision, stresses the need to place learners in situations that are meaningful to them. It considers that all learning is linked to the social situation or context in which it is produced. In the case under analysis here, this view of learning has developed into the current notion of "learning communities" and finds its expression in the attempt to make the role play a "situated activity." "Situated activity" is an activity that is both meaningful and credible: meaningful because it focuses on a problem that is important to the subjects and credible because it is life-like (in spite of the inevitable fact that it is presented by means of a computer screen).

Credibility is the main characteristic in each of the situations contained within a role play, because it is impossible to get a subject involved if he or she does not consider the situation to be realistic. This realism is achieved by the careful study and use of three types of factors: physical, linguistic, and narrative:

1. ***Physical.*** The situations are credible as far as the physical setting and the characters' ways of dressing and moving are concerned. The actors chosen were of ages between 16 and 20 and were encouraged to give their performances as spontaneously as possible. Furthermore, the interactive situations were played out in settings not unfamiliar to young people: a hotel room, a beach after sunset, a discotheque, and a party in the house of friends.
2. ***Linguistic.*** As in other simulations or pseudosimulations, in role plays such as this, it is the content that conditions the simulation and the realism of the situations, and this is primarily language-based: the game is largely concerned with taking decisions but also with following the reasoning that leads to a decision and, finally, opting between two alternatives that represent opposite, or markedly different, points of view. For this reason, the characters' ways of speaking had to be selected with particular care in order to capture as closely as possible the way young people express themselves.
3. ***Narrative.*** The game's story line is organized around the metaphor of a journey. To ensure realism, the journey involves a group of friends visiting various European cities one summer by train. At each stop, a new situation can be introduced, and in this way, the journey serves as a narrative thread linking each situation (a thread that would have been difficult to find if the situations had occurred as isolated incidents). Having said this, however, each situation is independent of those that precede it and stands as a separate situation in its own right, with its own problem and solution.

The outcomes of each decision are not revealed, however, until some months after the holiday. On the one hand, it needs to be like this in order to give greater realism to the game, as there exists the so-called "window period" during which infection with the AIDS virus cannot be diagnosed, even when it has occurred. On the other hand, it captures the particular characteristic of the apparent disconnection between the risk behavior and the onset of awareness: when the antibody test can be performed, the subjects have forgotten the practices that have led to the results they

are given. In this case, the game indicates the situations and practices of risk during which the infection could have occurred.

The Play Environment as a Construction of the Player's Identity

This aspect is common to games in general, and is particularly relevant in computer games, including role plays. The setting provides a safe environment in which players can experiment with activities that involve a certain risk; they can break the rules in some way, or they can improvise their reactions to an unexpected situation. In role plays, participants represent different personalities and act accordingly but are not liable to suffer from any negative consequences of the decisions they take. The role-play scenario is a safe environment, but it is also a learning environment in which the participants' identities are modified by the ways in which they play the roles of the imaginary characters. This connection between learning and identity has been highlighted by Wenger (1998) and more recently by Gee (2003) with respect to video games.

In the case of AIDS prevention, role play allows participants to create a situation in which they play the parts of adolescents through their identification with their roles, but at the same time without the risk of suffering the negative consequences of the decisions they make. The play environment, the identification with the character, the active choices made in selecting a narrative and constructing meaning, and the "realistic," credible nature of the situations act synergistically in the educational design.

INTERACTIVE MULTIMEDIA APPLICATIONS

The decisions taken regarding project aims and content have a direct bearing on several aspects of the multimedia production, as well as the interactive applications.

Multimedia Production

The multimedia production typically includes the graphic interface design, the media, and the programming. The graphic interface was designed following criteria similar to those adopted in the content specifications, which seek to make them suitable for a young end user. The overall design comprises several points of focus that vary as the journey takes its course, and this, in part, reflects the distinctive sections of the project: the hypertext reflects a more conventional presentation of the project's contents, the role play uses a black background combined with a number of innovations (which are described below in the description of the interactive applications), and, interestingly, a small game serves to introduce the various characters, each using a variation in the graphic interface.

The overriding idea in determining the graphic interface was to come up with a product that was as close as possible to the aesthetic design that young people are used to seeing in computer games, multimedia leisure activities, and even in video clips and television. Unlike many adult users, children and young people are particularly critical of graphic interface features, and many educational programs fail to make any attempt to capture the graphic aesthetics that appeal to them. It is also true that the cultural similarity between the two countries in which the CD-ROM was distributed, Italy and Spain, helped unify the graphic criteria used.

The media used included video (nine sequences of around 5 minutes each, bearing in mind that the last sequence had to be divided in four: two depending on the selection of the sex of the character, one showing infection with the virus, and the other showing a situation in which the disease is not contracted), several hundred stills for the simulated dialogues, and music.

The decision to use video, as well as that to use photographs, was made to promote user identification with the characters in the role

play. Unlike animated images, which have to be extremely realistic or of high quality, video encourages identification with the characters, and with the story, more easily and more directly. The performances of the actors, and their facial expressions, ensure that in the mind of the user the actors and the characters are inseparable. The stills were taken using conventional photographic techniques, predominantly in close up, with some shots taken at a slightly longer range. The reasons for this are well known in the cinema, as close-ups of the face, capturing the actor's facial expressions and eyes, help the viewer identify with the character.

In short, the choice of the media was based on the need to make the story as realistic as possible, and as such, both video and photography were seen as essential elements in capturing the emotional impact of the story.

The computer technology and programs used were conventional: we used Macromedia Director for the design, given its versatility and the ease with which different media can be integrated, in addition to its multiplatform capacity, linked to QuickTime. A special Internet version was not designed, given the video size (an average of 50 MB), which would have meant it could not even be used on wideband networks. Furthermore, most of the users are secondary schools, or citizen support groups, or young people in general, who typically only have access to an ISDN or ADSL modem connection with a capacity to download video images that is extremely limited.

Interaction

At its most basic, the interaction element is organized around a simple navigational structure in which the user must choose between the information section and the role play. Below we shall see how these two options are interconnected. The information section consists of a hypertext comprising graphics and text, which provide basic information. The text is adapted to the users and is extremely user friendly.

The role play, however, has a more complex interactive format, as it combines a story told in video images with the need to make decisions (stills). The video story is interrupted when a conflict arises between the characters, and the user is left not knowing how it will evolve. The audiovisual story serves, then, to motivate the user and also to present an unresolved problem. The user then needs to respond to this problem according to the role he or she has adopted in the game, which is the character with which the user by now identifies. Therefore, the interaction with the content of the program centers on the choice of various options in a simulated conversation with the main characters—depending on which of two options given is selected, the subsequent options presented will vary.

As described above, once the interaction has been initiated, an internal narrative is constructed in accordance with the options selected: the course taken by the dialogue is determined by the choices that are made. In other words, the application itself constructs the narrative and the course taken by subsequent choices, using a preprogrammed dialogue that is inserted between nodes in the decision tree. This dialogue takes the form of various screens, very much in the style of a photo-novel.

One of the most interesting aspects of this system is that it allows the decisions to be thought through. In other words, there is no time pressure whatsoever on the user, who is free to make his or her decision when they feel fit. This means that the dialogues between one decision and the next can be read and given due thought, as they result in the need for a new choice to be made. The application includes the possibility of returning to the video sequence at any time, as well as changing the choices made, should the user feel he or she made a mistake or wishes to select the other option. The decisions taken are depicted in the form of mini graphic images, so that it is always possible to go back to one of them (although, of course, changing the earliest decisions means that all subsequent decisions are lost).

Image 1. Decision-taking structure in the role-playing game. The video still on the left allows the player to view the whole situation. The small circular images show the previous decisions that have been taken. The player can return to these if he or she wishes to reconsider the decision. The two main images in the middle show the options that the player has to choose between for the situation just viewed: by placing the mouse over each image a text appears summarising the option, while the other image fades out. The small image of the main character at the bottom of the screen reminds the player that they have adopted the role of the female character.

Interaction during the game enables the more complex decisions, or those that require factual information, to be linked up with the hypertext system in the information section of the program. If the young user wishes to receive information before taking a decision, he or she can launch the information system, although the hypertext capacities of the system are restricted: it is only possible to navigate those screens containing relevant information for the decision that has to be taken at that moment. This is a design choice, implemented so that the user does not cast the net too wide when searching for information and so as to give contextualized support only.

Educational Applications and User Tests

The project was distributed with the national newspapers and was also sent to educational resource centers. This distribution plan ensured a wide audience but made it difficult to conduct any evaluation of its impact. However, an informal method of evaluation was employed by conducting interviews with the users. The results of this (for a detailed account see Rodríguez Illera et al., 1999) revealed a very high approval rating, while respondents claimed that they had identified easily with the role play. The only criticisms received concerned features of the interface, in particular, in the information section, where some users felt the text was too dense and the letter size too small.

This somewhat limited analysis concerned the programs used in groups with a teacher. For such purposes, the program is accompanied by a detailed guide for educational contexts, one for teachers and another for the end users [http://www.noaids.org]. The latter suggests various activities and means of comprehension for users working by themselves. This possibility was specifically included so as to allow those young people who feel uneasy or who are reluctant to express their opinions in public use the program.

DISCUSSION

We believe that the project demonstrates the means of integrating multimedia capabilities within an instructional design that has clear educational objectives, incorporating elements of interaction to reinforce these objectives within an overall framework that comprises a role-playing game. We would highlight the following aspects of the project:

1. The search for design simplicity at all times: Rather than use multimedia capabilities for their own sake—including animation, audio elements, and music—with little bearing on the educational purpose of the project, we sought to use only those elements necessary to meet the project's specific educational aims. This does not mean that we ruled out the use of more complex interactive capabilities, in particular, given the type of end user we are dealing with. Indeed, the program incorporates a section in which a wide range of multimedia capabilities is used with the primary purpose of entertaining the user: before embarking on the journey, the program allows the user to get to know the main characters of the story better by using a number of short interactive games that differ for each of the six characters. However, this part is clearly isolated from the rest of the program and does not interfere with either the information section or the role-playing game itself.
2. The use of multimedia is designed to facilitate the telling of the story, to create dramatic tension and climatic situations, and to introduce the conflicts. In other words, the features of audiovisual language are used—in this case, features that are more emotive than informative and features that ensure the user identifies with the story's characters.
3. It is true that we do not have an institutionalized means of representing the language of multimedia (Plowman, 1994), and that, therefore, it is difficult to know the significance of certain multimodal configurations (Kress, 2003), such as those that are present in designing complex screens. However, in the case we are concerned with here, the central place of the video in the construction of the story, as well as the absence of the simultaneous appearance of text, means that it can be considered as the dominant component of multimedia, and it can be thought of as being largely responsible for constructing the meaning.
4. The program combines a story, which has its own predefined meaning, with elements of interaction that provide a new meaning and a situation that each user constructs via the decisions that he or she makes, creating a personal narrative along the path that is taken. This format employs interactive multimedia capabilities, while putting them at the service of educational objectives.

The Limits of Role Play

This project description has highlighted what we consider to be its successes, but a subsequent analysis enabled us to see where its limitations lay, in particular, those concerning its instructional design. As indicated, role play is a type of simula-

tion, albeit without any underlying mathematical model, in which it is easy to rehearse certain skills in a safe environment. The strength of the simulation lies in user identification with the characters (and with all the other aspects that are constructed using the multimedia). Once this has been achieved, it becomes virtually independent of the multimedia format that the subsequent interactive program adopts, though not of the logic underlying the choices that are made throughout the program and the story that develops. We believe that this principal feature of the project can be seen in terms of a theoretical construct similar to that present in situated learning and cognition: the attempt to get the young users to see it as something that they have to resolve in a particular way, using the elements that appear on the screen. The "magic" of multimedia applications is in the complete engagement of the user, in a similar way to that in which a book absorbs its reader (Hill, 1999), in other words, its ability to transport the reader or the user to a very high level of cognitive involvement, centered on the activities that they have to carry out. In short, it is the ability to make the user believe that the role play is a real and engaging situation.

The underlying logic of a multimedia role play differs from that of the goal-based scenarios proposed by Schank (1998), which might be considered as another strategy of situated learning. It responds more closely to those cases of ill-defined problems that are so typical of informal teaching and learning situations. The inadequate definition of the situation or the problem is characteristic of real problems, which, removed from experimental situations, need to be analyzed using multiple perspectives and argumentations and descriptions designed to capture their meanings. In the case of role plays, this need is apparent in the narratives of decision building (Cho & Jonassen, 2002): the characters resituate the choice taken using a simulated dialogue that follows a line of argument until a new decision is made.

If the objective of the role play were to be made explicit from the outset, such as "always use a condom in a risk situation," it would probably lose all interest, in particular for young people. However, if we had to teach skills that had been previously agreed upon with adult subjects, the choice of a scenario based on explicit objectives would be a more recommendable option. Yet, one of the characteristics of games that seek to simulate real situations is that the player does not always know the objective of the game, at least the first time it is played. This gives rise to a certain ambiguity between the objectives of the instructional design (which include a modeling of behavior in risk situations, as well as a set of negotiation skills via the choices to be made and the story that unfolds between the decisions) and those of the player playing the role game for the first time, who does not know very well what it comprises—identify with one of the characters, accompany him or her throughout the journey, and make decisions along the way—but without an explicit objective as to the target that needs to be reached. This ambiguity, or lack of definition as far as the player is concerned, results in a much more situated performance, as the player plays "as if" he or she were one of the characters, making the decisions that they consider to be "normal" whenever required to do so. If the game leads to the player contracting the infection because he or she has engaged in unsafe sexual practices, this simply emphasizes the need for reflection on these practices, reminding the player when and how the behavior occurred but giving the player the opportunity to make mistakes.

The Question of Feedback

Furthermore, as discussed earlier, in the case of AIDS, there is a marked time lag between the occurrence of the risk behavior and the realization of its consequences, which means it is not possible to offer immediate corrective feedback (which would be the most efficient way of doing so).

Several techniques are available for making subjects aware of the anticipated effects of their behavior: one such technique is that used by González (1995), who constructs a graphic simulator of the spread of an infection in a given population (a discotheque) based on sexual relation profiles. The simulator clearly shows how the infection spreads over time and its consequences in the medium and long terms. This technique is very useful for showing the effects on populations or groups and for understanding the epidemic nature of many diseases.

A further didactic technique for individual use, and which was in fact analyzed for use in this project, is that which is used in the application: ***If you love me, show me*** (Family of the Americas, 1995). Although it does not deal directly with AIDS but rather with sexual relations among young people, it uses an animated narrative to show the ups and downs in a date between a boyfriend and girlfriend. Told from the perspective of the girl, it adopts a highly conservative ideology. This undermines somewhat the veracity of the situation described, and the fact that it has few opportunities for interaction means that it is not of direct interest for us. However, it does introduce a form of behavior modeling that might be considered a form of anticipatory feedback: an imaginary character acts as "the conscience" of the teenage girl, pointing out to her when having to make a decision the hidden intentions of the male character and the consequences of a particular action. What is surprising about the technique is that it operates as an unsolicited source of help before the action occurs.

Both techniques are responses to very different approaches but are not especially applicable to the design of our project: in the first case, the simulator is applied to a group in which the profiles of sexual behaviour determine the consequences. It is not possible for subjects to place themselves within a group and experience the evolution for themselves, as the situation does not depend on their own decision-making skills. Furthermore, the behavior profiles are not necessarily recognizable by the individuals as being their own. In the second case, it is virtually impossible for the user to commit mistakes given its preventive nature, with the result that the type of learning is unlikely to be integrated within the subject's action schema. Schank (1999), following a long tradition of "active pedagogy," insists, rightly we believe, in the need to make mistakes and then to rectify these errors so that the actions committed become true learning experiences and modify our prior schema or scripts.

The solution adopted here is for the role play to reduce the period of real time (in fact, the so-called "window period" extends from three to six months), by using a time step that is resolved in the final situation. This means of representing the passing of time allows the player to receive delayed feedback, though it is in fact given during the same session in which the game is played. Given that the success of the game depends on it being as realistic as possible, this time difference does not have any major effect on the game's realism: first, it is a typical technique of audiovisual media and the language of the cinema; and, second, the final situation is not interactive and is used to reveal to each player the results of the game, depending on the character he or she has adopted. This technique allows us, albeit with some limitations, to overcome the problems of the apparent lack of connection between an action and its delayed consequences, as well as to be able to give feedback on the choices made in a very brief period of time (in the real game time). Furthermore, it does away with the need to introduce other solutions such as those mentioned, which would lead to interactions that are not always cohesive with the educational objectives.

However, any application such as the one analyzed here raises many unanswered questions. To what extent are the skills actually learned? Can we really speak of changes in attitude? Are the skills and attitudinal changes transferred to other situations? Clearly, it is not possible to answer

these questions directly, as we are dealing with complex skills. What is required is a longitudinal study, which in this case, as in others before, has been ruled out.

CONCLUSION

Role-playing games are complex multimedia applications, not just because of the technology they use but also because of the way in which this technology responds to an educational framework design that combines a constructivist approach with other concepts, such as the sociocultural modeling of the action and dialogues of argumentation. It would seem that some of the most recurring and justified criticisms that have been made of educational multimedia packages—namely, their technological and multimedia excesses, combined with a lack of pedagogic underpinnings—can be overcome when the educational design is central to the project and the technologies and the production of various multimedia elements are put at the service of the project.

Perhaps the most general conclusion is that each project requires a specific educational design. Just as different subjects are taught in different ways, multimedia applications should be far more specific in their instructional designs, whether their theoretical backgrounds are cognitivist or constructivist.

Equally, it does not appear that the changes in attitude or the transfers of skills are solely attributable to the use of multimedia tools, however complex or well designed they might be. Rather, they would seem to be the result of more than *one* educational action. From the perspective of health education and, in particular from that of AIDS prevention in the young, it would appear that multimedia role-playing games need to be complemented with more formal instruction techniques backed with a range of additional activities.

ACKNOWLEDGMENT

The project was funded by the EU programme "'Europe against AIDS," and was a joint undertaking between the cooperative group, CLAPS, of Pordenone, Italy, and the University of Barcelona (ICE), Spain. The author wishes to express his gratitude to Carlo Mayer, co-director on behalf of CLAPS, and to the Spanish team of Begoña Gros, Cristina Martínez, and María José Rubio.

INTRODUCTION

The evolution of mobile technologies and their convergence with the Internet enable the development of interactive services targeting users with heterogeneous devices and network infrastructures (Wang et al., 2004). Specifically, as far as cultural heritage and tourism are concerned, several systems offering location-based multimedia services through mobile computing and multimodal interaction have already appeared in the European research community (LOVEUS, n.d.; Karigiannis, Vlahakis, & Daehne, n.d.).

Although such services introduce new business opportunities for both the mobile market and the tourism sector, they are not still widely deployed, as several research issues have not been resolved yet, and also available technologies and tools are not mature enough to meet end user requirements. Furthermore, user heterogeneity stemming both from different device and network technologies is another open issue, as different versions of the multimedia content are often required.

This article presents the AVATON system. AVATON aims at providing citizens with ubiquitous user-friendly services, offering personalized, location-aware (GSM Association, 2003), tourism-oriented multimedia information related to the area of the Aegean Volcanic Arc. Towards this end, a uniform architecture is adopted in

order to dynamically release the geographic and multimedia content to the end users through enhanced application and network interfaces, targeting different device technologies (mobile phones, PDAs, PCs, and TV sets). Advanced positioning techniques are applied for those mobile user terminals that support them.

SERVICES

AVATON is an ambient information system that offers an interactive tour to the user (visitor) in the area of the Aegean Volcanic Arch (see http://www.aegean.gr/petrified_forest/). The system can serve both as a remote and as an onsite assistant for the visitor, by providing multimedia-rich content through various devices and channels:

- Over the Internet, via Web browsers with the use of new technologies such as rich-clients and multi-tier architecture in order to dynamically provide the content;
- With portable devices (palmtops, PDAs) and 2.5G or 3G mobile phones, which are capable of processing and presenting real-time information relevant to the user's physical position or areas of interest; and
- Via television channels—AVATON allows users to directly correlate geographic with informative space and conceivably pass from one space to the other, in the context of Worldboard (Spohrer, 1999).

With the use of portable devices equipped with positioning capabilities, the system provides:

- Dynamic search for geographical content, information related to users' location, or objects of interest that are in their proximity;
- Tours in areas of interest with the aid of interactive maps and 3-D representations of the embossed geography;
- Search for hypermedia information relative to various geographic objects of the map;
- User registration and management of personal notes during the tour that can be recalled and reused during later times; and
- Interrelation of personal information with natural areas or objects for personal use or even as a collective memory relative to visited areas or objects.

THE AVATON ARCHITECTURE

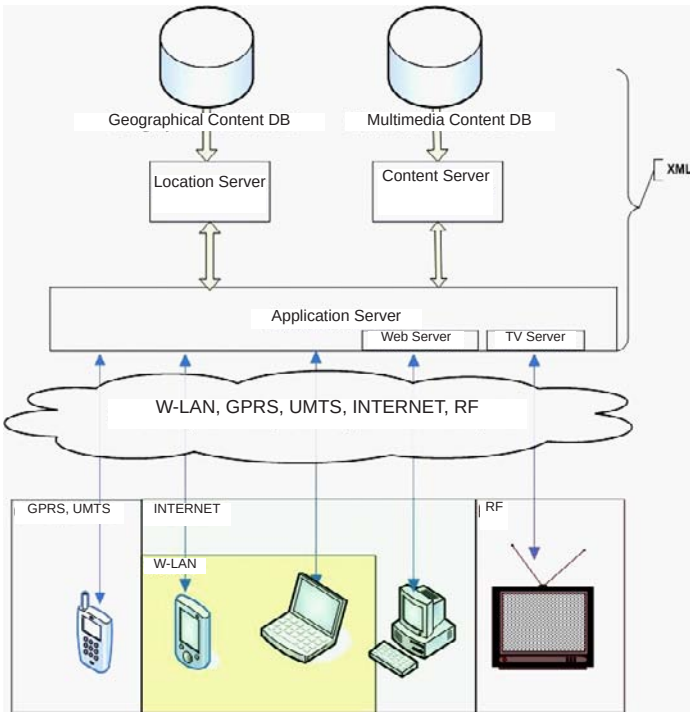
Overview

The AVATON system is based on a client-server architecture composed of three main server components: the application server, the content server, and the location server. The application server combines information and content from the content and location servers, and replies to client requests through different network technologies. The content is retrieved from two kinds of databases, the geographical and multimedia content DBs. The above architecture is shown in Figure 1.

In more detail:

- **Multimedia Content Database:** This database contains the multimedia content such as images, video, audio, and animation.
- **Geographical Content Database:** A repository of geographical content such as aerial photos, high-resolution maps, and relevant metadata.
- **Content Server:** The content server supplies the application server with multimedia content. It retrieves needed data from the multimedia content database according to user criteria and device capabilities, and responds to the application server.
- **Location Server:** Serves requests for geographical content from the application server by querying the geographical content data-

Figure 1. The AVATON architecture



base. The content retrieved is transformed into the appropriate format according to user device display capabilities and network bandwidth available.

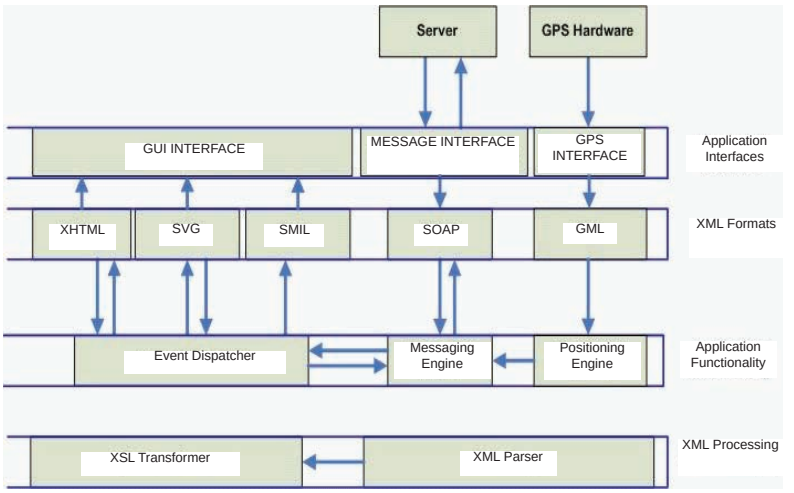
- **Application Server:** The application server receives requests from different devices through GPRS, UMTS (third-generation mobile phone), W-LAN, Internet (PDA, laptop, PC), and RF (television). The server identifies each device and transmits data in an appropriate format. More precisely, the application server incorporates a Web server and a TV server in order to communicate with PCs and televisions respectively.

Client

This section focuses on the mobile-phone and PDA applications. The scope of the AVATON system includes Java-enabled phones with color displays and PDAs with WLAN or GPRS/UMTS connectivity. While all the available data for the application can be downloaded and streamed over the network, data caching is exploited for better performance and more modest network usage.

When the users complete their registration in the system, they have in their disposal an interactive map that initially portrays the entire region as well as areas or individual points of interest. For acquiring user position, the system is using GPS. The client also supports multi-lingual implementation, as far as operational content is concerned, for example menus, messages, and help. These files are maintained as XML documents. XML is extensively used in order to ease the load of parsing different data syntaxes. A single process, the XML Parser is used for decoding all kinds of data and an XSL Transformer for transcoding them in new formats. The different XML formats are XHTML, SVG, SMIL, SOAP, and GML, as shown in Figure 2.

Figure 2. The XML-based technologies in the client side



Geographical Info Presentation

In order to render the geographical data, the client receives raster images for the drawing of the background map, combined with metadata concerning areas of interest and links to additional textual or multimedia information. The raster data are aerial high-resolution photographs of the region on two or three scales. Because of the high resolution of the original images, the client is receiving small portions, in the form of tiles from the *raster data processing engine* in the server side, which are used to regenerate the photorealistic *image layer* in a resolution that is suitable for the device used. The attributes of the geographical data are generated in vector ShapeFile (ESRI ShapeFile) format, which is quite satisfactory for the server side but not for lightweight client devices. So, a *SHP TO SVG converter* at the server side is regenerating the metadata in SVG format that can be viewed properly from a handheld device. As soon as the metadata is downloaded to the client device, a final filtering (XSLT transformation) is done and the additional layer is opposed to the image layer in the *SVG viewer.* On the *SVG data layer*, the user can interact with points of interest and receive additional information in the form of text or multimedia objects. The above are shown in Figure 3.

Multimedia Info Presentation

The presentation of multimedia information mainly depends on user position. The system is designed to provide audio and video clips, 3-D representations, and also textual information concerning each place of interest. Not all devices, though, receive the same content, since they differ in display, processor, or network speed. For that purpose, for each registered user, the system decides what kind of content is more suitable for them to receive and the multimedia content server generates the appropriate script. Depending on the available memory of the client's device, media objects stay resident in the cache memory so that frequently requested content is accessed without delays that occur due to network latency. In Figure 4 the components that are involved in the multimedia presentation are shown. The *TourScript Data* contains the script which describes the multimedia presentation. It is transcoded inside the *SMIL generator* to a SMIL message that follows the XML syntax, so that it can be incorporated seamlessly to the messages

Figure 3. Client-side map rendering

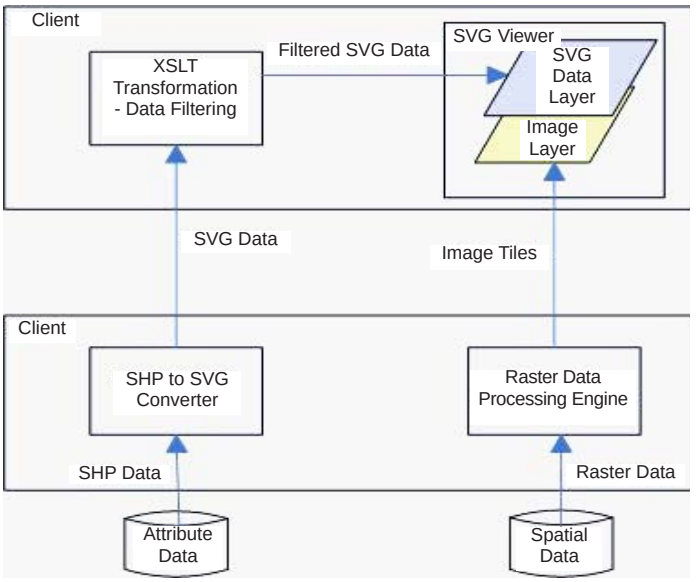


Figure 4. Client-side map rendering

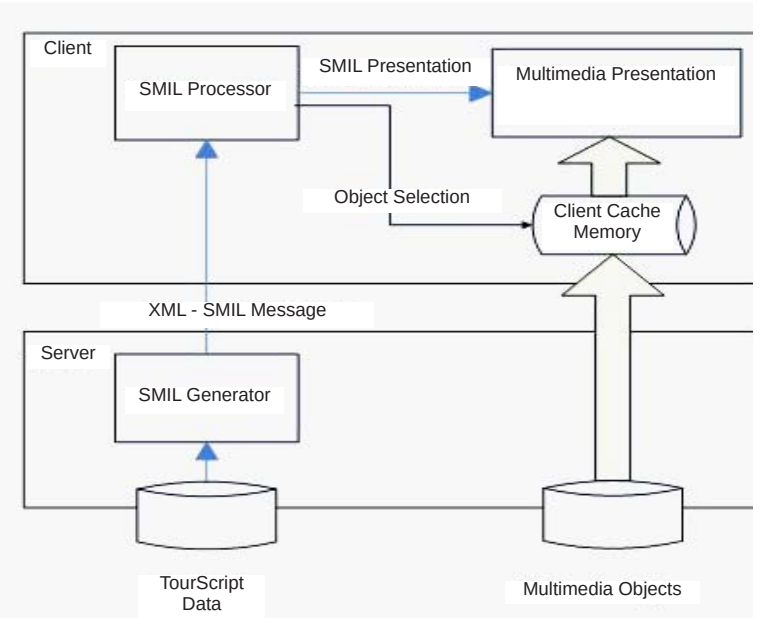

that are exchanged in the AVATON system. At the client side, the SMIL message is received by the *SMIL processor* which coordinates the process of fetching the *multimedia objects* from the *client cache memory* to the suitable renderer, so that the *multimedia presentation* can be completed.

Location Server

The location server is the component that handles the geographical content of the AVATON system. It provides a storage system for all geographical data and allows querying of its contents through location criteria, such as global position and areas of interest. Content management is based on a PostgreSQL (http://www.postgres.org) relational database. A JDBCInterface uses the JDBC APIs in order to provide support for data operations. A GISExtension is also present, based on PostGIS (http://www.postgis.org), in order to enable the PostgreSQL server to allow spatial queries. This feature is utilized through a GISJDBCInterface, a PostGIS layer on top of PostgreSQL.

Cartographic Data

Concerning the photorealistic information, the user can choose from several distinct zoom levels. The mobiles phones and PDAs in the market that support GPRS or WLAN have displays of different resolutions that, in most cases, are multiples of 16 pixels. Hence, the location server can generate tiles with a multiple of 16p x 16p, which can be presented in the user's mobile device. The server always holds multiple resolutions for every level of cartographic (photographic) information. The levels of cartographic information define the degree of focus.

Apart from the photographic layer, additional layers of vector information also exist, and their size is approximately 5% or 10% of the corresponding photographic. Therefore, in practice, every device will initially request from the server the cartographical information with the maximum resolution this device can support. Hence, the server decides the available resolution that best corresponds to the requested resolution from the device. The size of every tile is approximately 1K. The devices with greater resolution per tile receive more files, with greater magnitude, for every degree of focus due to the higher resolution.

Multimedia Content Server

The multimedia content server component comprises the major unit that controls the mixing and presentation of different multimedia objects. Its purpose is to upload all the objects necessary and present them in a well-defined controlled order that in general depends on the user position, interactions, and tracking information available. The multi-lingual audiovisual information scheduled for presentation is coordinated so that several objects may be presented simultaneously. The multimedia content server component is also responsible for choosing "relevant" objects for the user to select among in the case the user requires more information on a topic. The multimedia content server interfaces with the multimedia content database, a relational database storing the multimedia content. The database is organized thematically and allows the creation of hierarchical structures. It also contains a complete list of multimedia material, covering all content of the physical site, such as 3D reconstructed plants, audio narration, virtual 3D models, avatar animations, and 2D images.

Media Objects

As mentioned already, the multimedia content server is responsible for mixing the basic units of multimedia information. These elements are hierarchically ordered. At the finest level of granularity, there are atomic objects called MediaObjects with specializations such as AudioMediaObject, ImageMediaObject, 3DMediaObject, and CompositeMediaObject. These objects contain the

actual data to be rendered along with additional profile metadata characterizing them. At a higher level of complexity, a TourScript represents an ordered sequence of MediaObjects, all of which are to be presented if the script is chosen.

According to user requirements, the user will be able to navigate through the site in a geographically based tree. This is made possible through the use of points of interest (PoI) and areas of interest (AoI). A PoI can only contain TourScripts and can be viewed as the end node of the site tree. In contrast, an AoI may contain either another PoI, an AoI, or TourScripts. This allows the system to map the actual site into a hierarchy model containing PoI at the top and MediaObject components at the leaf level.

The multimedia content server is also responsible for managing this site-tree for the entire site. Moreover it is responsible for traversing it. The use of the site tree is quite interesting: when a media object, for instance *audio* object, is presented to the user, it belongs to a node in the site hierarchy. Figure 5 shows the structure of the site in a tree view as described previously. The multimedia content server is responsible for coordinating the rendering components in order to provide a synchronized presentation to the user, according to user preferences, position, and commands.

Deployment and Usage

Based on the proposed architecture, the AVATON services are being deployed to physical sites within the Aegean Volcano Arc (such as Santorini and Lesvos islands) and evaluated by real end users under different scenarios. The main air interfaces that will be used by the system (along with standard wired access through common LANs or the Internet) are:

- **WLAN:** A standard 802.11b wireless access network provides connectivity for users equipped with portable devices (such as PDA with built-in WLAN cards or laptops).
- **GPRS/UMTS:** For mobile users and smart phones, access will be provided through the GSM network, using GPRS (Bettsteter, Vögel, & Eberspächer, 1999). This restricts the system from providing video or 3-D animations to such users, and the services offered are focused on text, images (including map information), and short audio. As GPRS is already packet oriented, our implementation can be easily transferred to UMTS, if available.

Figure 5. Hierarchy formulation of media objects at the multimedia content server

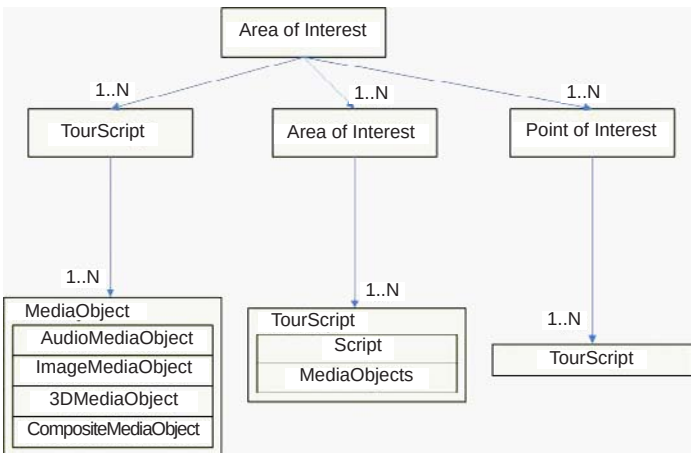

Figure 6. Implementation plan for the Lesvos island site

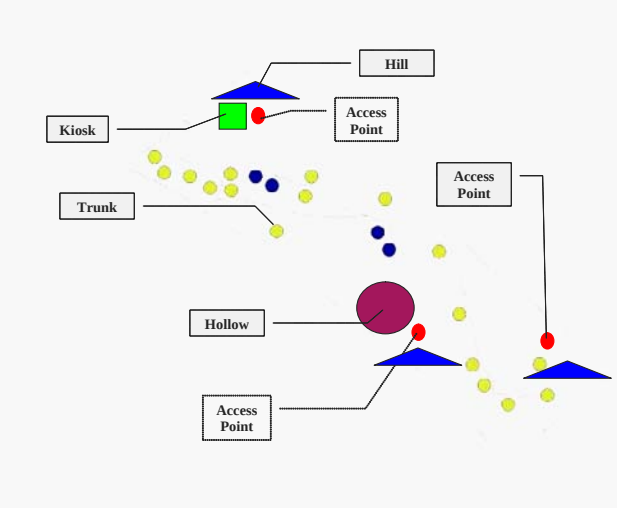

Figure 7. SVG map and interface

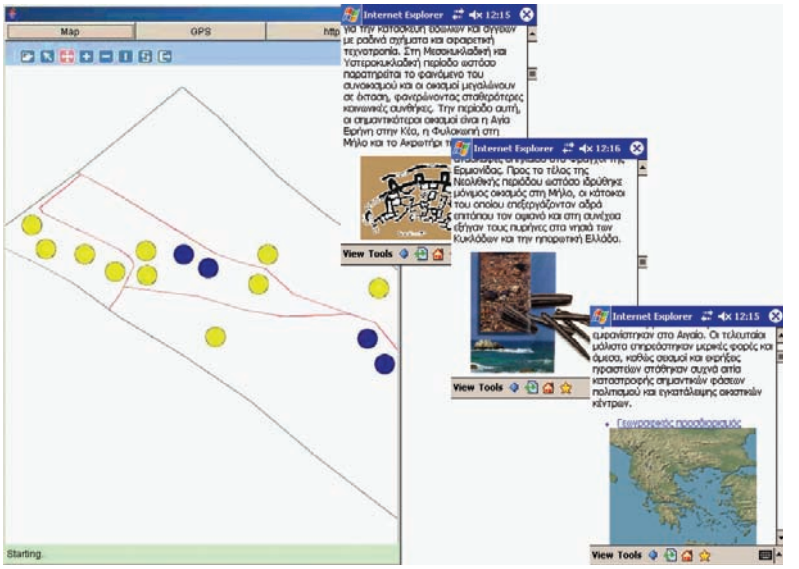

In Figure 6, the actual implementation plan is given for the location of the Sigri Natural History Museum on Lesvos island. The area consists of an open geological site, the Petrified Forest, where the ash from a volcanic eruption some 15 to 20 million years ago covered the stand of sequoia trees, causing their petrification. Wireless access is provided by the use of a 3 Netgear 54Mbps access point equipped with additional Netgear antennas in order to overcome the physical limitations of the area (hills, trunks, and hollows).

Visitors to the site are equipped with PDAs or smart phones (provided at the entrance kiosk) and stroll around the area. A typical scenario consists of the following: The users enter the archaeological site and activate their devices. They then perform

a login and provide personal details to the server, such as username, language selection, and device settings. The client then requests from the server and loads the map of the area in SVG (http://www.w3.org/TR/SVG) format, as seen in Figure 7. The circles on the map present distinct points of interest (yellow indicating trees and blue indicating leafs). The application monitors the users' location and updates the SVG map in real time, informing the users of their position. The SVG map is interactive, and when the users enter the vicinity of a point of interest, the application automatically fetches and displays (via their browser or media player) the corresponding multimedia content (in the form of HTML pages, audio, or video) at the requested language. The users are also able to navigate manually through the available content and receive additional information on topics of their interest. During the tour, the users' path is being tracked and displayed (the red line on Figure 7) in order to guide them through the site. They are also able to keep notes or mark favorite content (such as images), which can be later sent to them when they complete the tour.

FURTHER WORK

The system is currently being deployed and tested in two archeological sites. Users are expected to provide useful feedback on system capabilities and assist in further enhancements of its functionality. Also, as 3G infrastructure is being expanded, incorporation of the UMTS network in the system's access mechanisms will provide further capabilities for smart phone devices and also use of the system in areas where wireless access cannot be provided.

Towards commercial exploitation, billing and accounting functionalities will be incorporated into the proposed architecture. Finally, possible extensions of the system are considered in order to include other cultural or archeological areas.

KEY TERMS

Cartographic Data: Spatial data and associated attributes used by a geographic information system (GIS).

Content Provider: A service that provides multimedia content.

Location-Based Services: A way to send custom advertising and other information to cell phone subscribers based on their curent location.

Multimedia: Media that usesmultiple forms of information content and information processing (e.g., text, audio, graphics, animation, video, interactivity) to inform or entertain the (user) audience.

Network: A network of telecommunications links arranged so that data may be passed from one part of the network to another over multiple links.

Tourism: The act of travel for predominantly recreational or leisure purposes, and the provision of services in support of this act.

Chapter 4.15
Software Engineering for Mobile Multimedia
A Roadmap

Ghita Kouadri Mostéfaoui
University of Fribourg, Switzerland

ABSTRACT

The abstract should be changed to this new abstract: Research on mobile multimedia mainly focuses on improving wireless protocols in order to improve the quality of services. In this chapter, we argue that another perspective should be investigated in more depth in order to boost the mobile multimedia industry. This perspective is software engineering which we believe it will speed up the development of mobile multimedia applications by enforcing reusability, maintenance, and testability. Without any pretense of being comprehensive in its coverage, this chapter identifies important software engineering implications of this technological wave and puts forth the main challenges and opportunities for the software engineering community.

INTRODUCTION

A recent study by Nokia (2005) states that about 2.2 billion of us are already telephone subscribers, with mobile subscribers now accounting for 1.2 billion of these. Additionally, it has taken little more than a decade for mobile subscriptions to outstrip fixed lines, but this still leaves more than half the world's population without any kind of telecommunication service. The study states that this market represents a big opportunity for the mobile multimedia industry.

Research on mobile multimedia mainly focuses on improving wireless protocols in order to improve the quality of service. In this chapter, we argue that another perspective should be investigated in more depth in order to boost the mobile multimedia industry. This perspective is software engineering which we believe it will speed up the development of mobile multimedia applications by enforcing reusability, maintenance, and

testability of mobile multimedia applications. Without any pretense of being comprehensive in its coverage, this chapter identifies important software engineering implications of this technological wave and puts forth the main challenges and opportunities for the software engineering community.

ORGANIZATION OF THIS CHAPTER

The next Section presents the state of the art of research in mobile multimedia. The section "What Software Engineering Offers to Mobile Multimedia?" argues on the need for software engineering for mobile multimedia. The section "Contributions to 'Mobile' Multimedia Software Engineering" surveys initiatives in using software engineering techniques for the development of mobile multimedia applications. The section "Challenges of Mobile Multimedia Software Engineeering " highlights the main challenges of mobile multimedia software engineering. Some of our recommendations for successfully bridging the gap between software engineering and mobile multimedia development are presented. The last section concludes this chapter.

STATE OF THE ART OF CURRENT RESEARCH IN MOBILE MULTIMEDIA

I remember when our teacher of "technical terms" in my Engineering School introduced the term "Multimedia" in the middle of the 1990s. He was explaining the benefits of Multimedia applications and how future PCs will integrate such capabilities as a core part of their design. At this time, it took me a bit before I could understand what he meant by integrating image and sound for improving user's interactivity with computer systems. In fact, it was only clear for me when I bought my first "Multimedia PC."

Multimedia is recognized as one of the most important keywords in the computer field in the 1990s. Initially, communication engineers have been very active in developing multimedia systems since image and sound constitute the langua franca for communicating ideas and information using computer systems through networks. The broad adoption of the World Wide Web encouraged the development of such applications which spreads to other domains such as remote teaching, e-healthcare, and advertisement. People other than communication engineers have also been interested in multimedia like medical doctors, artists, and people in computer fields such as databases and operating systems (Hirakawa, 1999).

Mobile multimedia followed as a logical step towards the convergence of mobile technologies and multimedia applications. It has been encouraged by the great progress in wireless technologies, compression techniques, and the wide adoption of mobile devices. Mobile multimedia services promote the realization of the ubiquitous computing paradigm for providing anytime, anywhere multimedia content to mobile users. The need for such content is justified by the huge demand for a quick and concise form of communication–compared to text—formatted as an image or an audio/video file. A recent study driven by MORI, a UK-based market researcher (LeClaire, 2005), states that the demand for mobile multimedia services is on the rise, and that the adoption of mobile multimedia services is set to take off in the coming years and will drive new form factors. The same study states that 90 million mobile phones users in Great Britain, Germany, Singapore, and the United States, are likely to use interactive mobile multimedia services in the next two years.

We are looking at the cell phone as the next big thing that enables mobile computing, mainly because phones are getting smarter" Burton Group senior analyst Mike Disabato told the E-Commerce Times. "We'll see bigger form factors coming in some way, shape or form over the next

few years. Those form factors will be driven by the applications that people want to run.

In order to satisfy such a huge demand, research has been very active in improving current multimedia applications and in developing new ones driven by consumers' needs, such as mobile IM (Instant Messaging), group communication, and gaming, along with speed and ease of use. When reviewing efforts in research on mobile multimedia, one can observe that most of the contributions fall into the improvement of wireless protocols and development of new mobile applications.

Mobile Networks

Research on wireless protocols aims at boosting mobile networks and Internet to converge towards a series of steps:

- **WAP:** In order to allow the transmission of multimedia content to mobile devices with a good quality/speed ratio, a set of protocols have been developed and some of them have been already adopted. The wireless application protocols (WAP), aim is the easy delivery of Internet content to mobile devices over GSM (global system for mobile communications), is published by the WAP Forum, founded in 1997 by Ericsson, Motorola, Nokia, and Unwired Planet. The WAP protocol is the leading standard for information services on wireless terminals like digital mobile phones and is based on Internet standards (HTML, XML, and TCP/IP). In order to be accessible to WAP-enabled browsers, Web pages should be developed using WML (Wireless Markup Language), a mark-up language based on XML and inherited from HTML.
- **GPRS:** The General Packet Radio Service is a new non-voice value added service that allows information to be sent and received across a mobile telephone network (GSM World, 2005). GPRS has been designed to facilitate several new applications that require high speed such as collaborative working, Web browsing, and remote LAN access. GPRS boosts data rates over GSM to 30-40 Kbits/s in the packet mode.
- **EDGE:** The Enhanced Data rates for GSM Evolution technology is an add-on to GPRS and therefore cannot work alone. The EDGE technology is a method to increase the data rates on the radio link for GSM. It introduces a new modulation technique and new channel coding that can be used to transmit both packet-switched and circuit-switched voice and data services (Ericsson, 2005). It enjoys a data rate of up 120-150 Kbits/s in packet mode.
- **UMTS:** Universal Mobile Telecommunications Service is a third-generation (3G) broadband, packet-based transmission of text, digitized voice, video, and multimedia at data rates up to 2 megabits per second (Mbps) that offers a consistent set of services to mobile computer and phone users no matter where they are located in the world (UMTS, 2005).

Research on wireless protocols is still an active field supported by both academia and leading industry markets.

Mobile Multimedia Applications

With the advantages brought by third-generation (3G) networks like the large bandwidth, there are many chances that PDAs and mobile phones will become more popular than PCs since they will offer the same services with mobility as an added-value. Jain (2001) points out that important area where we can contribute important ideas is in improving the user's experience by identifying the relevant applications and technology for mobile multimedia.

Currently, the development of multimedia applications for mobile users is becoming an active field of research. This trend is encouraged by the high demand of such applications by mobile users from different fields of applications ranging from gaming, rich-information delivery, and emergencies management.

WHAT SOFTWARE ENGINEERING OFFERS TO MOBILE MULTIMEDIA?

Many courses on software engineering multimedia are taught all over the world. Depicting the content of these courses shows a great focus on the use of multimedia APIs for human visual system, signal digitization, signal compression, and decompression. Our contribution, rather, falls into software engineering in its broader sense including software models and methodologies.

Multimedia for Software Engineering vs. Software Engineering for Multimedia

Multimedia software engineering can be seen in two different, yet complementary roles:

1. The use of multimedia tools to leverage software engineering
2. The use of software engineering methodologies to improve multimedia applications development

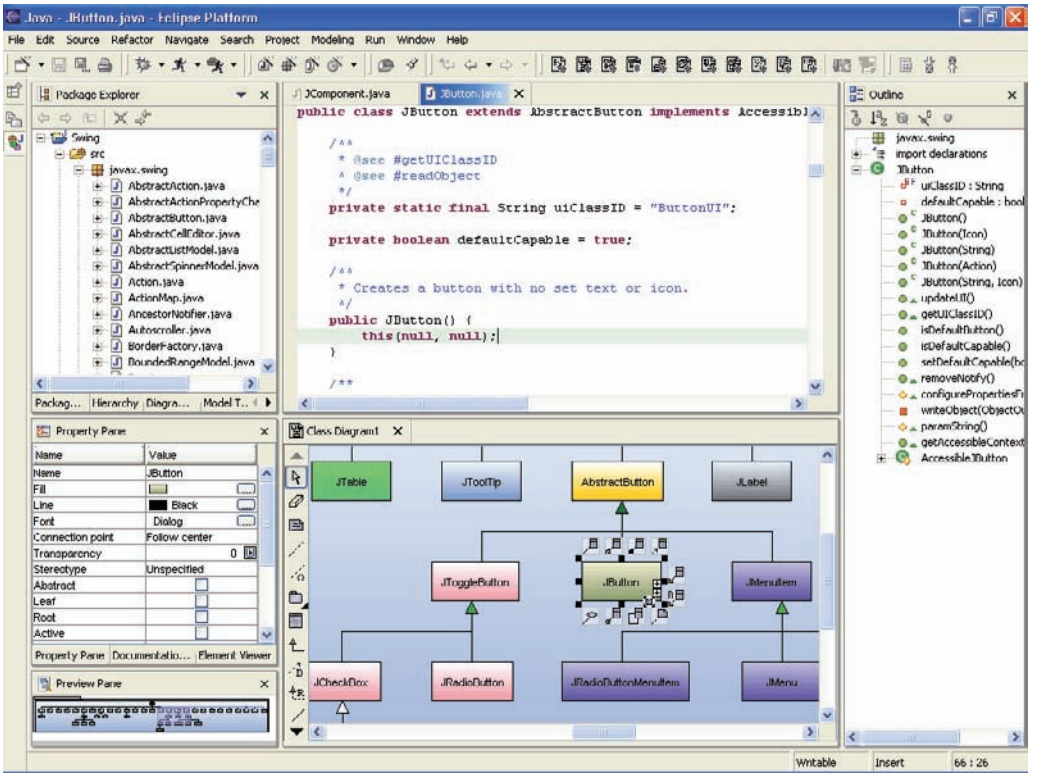
Examples of the first research trail are visual languages and software visualization. Software Visualization aims at using graphics, pretty-printing, and animation techniques to show program code, data, and dependencies between classes and packages. Eclipse (Figure 1), TogetherSoft, and Netbeans are example tools that use multimedia to enhance code exploration and comprehension.

The second research trail is a more recent trend and aims at improving multimedia software development by relying on the software engineering discipline. An interesting paper by Masahito Hirakawa (1999) states that software engineers do not seem interested in multimedia. His guess is that "they assume multimedia applications are rather smaller than the applications that software engineers have traditionally treated, and consider multimedia applications to be a research target worth little." He argues that the difference between multimedia and traditional applications is not just in size but also the domain of application. While there is no disagreement on this guess, it would be more appropriate to expand. We claim that there is a lack of a systematic study that highlights the benefits of software engineering for multimedia. Additionally, such study should lay down the main software approaches that may be extended and/or customized to fit within the requirements of "mobile" multimedia development.

Due to the huge demand of software applications by the industry, the U.S. President's Information Technology Advisory Committee (PITAC) report puts "Software" as the first four priority areas for long-term R&D. Indeed, driven by market pressure and budget constraints, software development is characterized by the preponderance of ad-hoc development approaches. Developers don't take time to investigate methodologies that may accelerate software development because learning these tools and methodologies itself requires time. As a result, software applications are very difficult to maintain and reuse, and most of the time related applications-domains are developed from scratch across groups, and in the worst case in the same group.

The demand for complex, distributed multimedia software is rising; moreover, multimedia software development suffers from similar pitfalls discussed earlier. In the next section, we explore the benefits of using software engineering tools and methodologies for mobile multimedia development.

Figure 1. A typical case tool



Software Engineering for Leveraging Mobile Multimedia Development

Even if mobile multimedia applications are diverse in content and form, their development requires handling common libraries for image and voice digitization, compression/decompression, identification of user's location, etc. Standards APIs and code for performing such operations needs to be frequently duplicated across many systems. A systematic reuse of such APIs and code highly reduces development time and coding errors. In addition to the need of reuse techniques, mobile multimedia applications are becoming more and more complex and require formal specification of their requirements. In bridging the gap between software engineering and mobile multimedia, the latter domain will benefit from a set of advantages summarized in the following:

- **Rapid development of mobile multimedia applications:** This issue is of primordial importance for the software multimedia industry. It is supported by reusability techniques in order to save time and cost of development.
- **Separation of concerns:** A mobile multimedia application is a set of functional and non-functional aspects. Examples are security, availability, acceleration, and rendering. In order to enforce the rapid development of applications, these aspects need to be developed and maintained separately.
- **Maintenance:** This aspect is generally seen as an error correction process. In fact, it is broader than that and includes software enhancement, adaptation, and code understanding. That's why, costs related to software maintenance is considerable and

mounting. For example, in USA, annual software maintenance has been estimated to be more than $70 billion. At company-level, for example, Nokia Inc. used about $90 million for preventive Y2K-bug corrections (Koskinen, 2003).

In order to enforce the requirements previously discussed, many techniques are available. The most popular ones are detailed in the next Section including their concrete application for mobile multimedia development.

CONTRIBUTIONS TO "MOBILE" MULTIMEDIA SOFTWARE ENGINEERING

This section explores contributions that rely on software design methodologies to develop mobile multimedia applications. These contributions have been classified following three popular techniques for improving software quality including the ones outlined above. These techniques are: middleware, software frameworks, and design patterns.

Middleware

An accustomed to conferences in computer science has with no doubt attended a debate on the use of the word "middleware." Indeed, it's very common for developers to use this word to describe any software system between two distinct software layers, where in practice; their system does not necessarily obey to middleware requirements.

According to (Schmidt & Buschmann, 2003) middleware is software that can significantly increase reuse by providing readily usable, standard solutions to common programming tasks, such as persistent storage, (de)marshalling, message buffering and queuing, request de-multiplexing, and concurrency control. The use of middleware helps developers to avoid the increasing complexity of the applications and lets them concentrate on the application-specific tasks. In other terms, middleware is a software layer that hides the complexity of OS specific libraries by providing easy tools to handle low-level functionalities.

CORBA (common object request broker architecture), J2EE, and .Net are examples middleware standards that emerge from industry and market leaders. However, they are not suitable for mobile computing and have no support for multimedia.

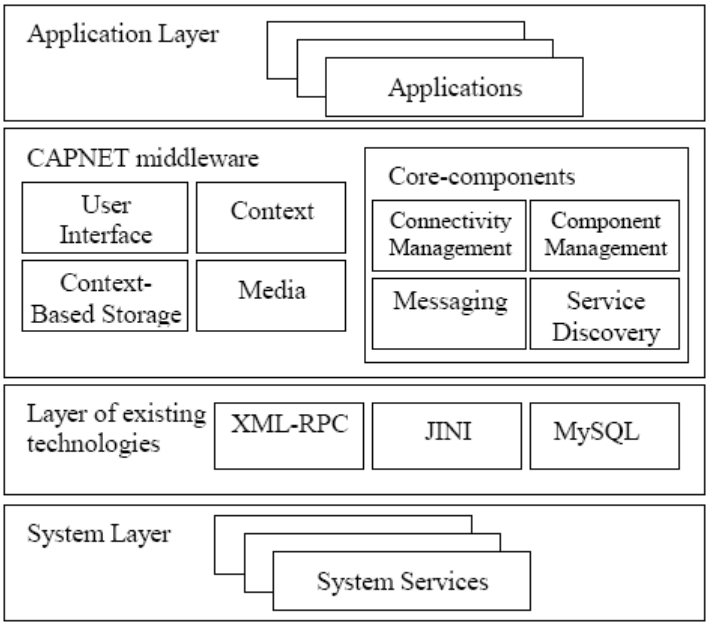
Davidyuk, Riekki, Ville-Mikko, and Sun (2004) describe CAPNET, a context-aware middleware which facilitates development of multimedia applications by handling such functions as capture and rendering, storing, retrieving and adapting of media content to various mobile devices (see Figure 2). It offers functionality for service discovery, asynchronous messaging, publish/subscribe event management, storing and management of context information, building the user interface, and handling the local and network resources.

Mohapatra et al. (2003) propose an integrated power management approach that unifies low level architectural optimizations (CPU, memory, register), OS power-saving mechanisms (dynamic voltage scaling) and adaptive middleware techniques (admission control, optimal transcoding, network traffic regulation) for optimizing user experience for streaming video applications on handheld devices. They used a higher level middleware approach to intercept and doctor the video stream to compliment the architectural optimizations.

Betting on code portability, Tatsuo Nakajima (2002) describes a java-based middleware for networked audio and visual home appliances executed on commodity software. The high-level abstraction provided by the middleware approach makes it easy to implement a variety of applications that require composing a variety of functionalities.

Middleware for multimedia networking is currently a very active area of research and standardization.

Figure 2. The architecture of CAPNET middleware (Davidyuk et al., 2004)



Software Frameworks

Suffering from the same confusion in defining the word middleware, the word "framework" is used to mean different things. However, in this chapter, we refer to frameworks to software layers with specific characteristics we detail in the following. Software frameworks are used to support design reuse in software architectures. A framework is the skeleton of an application that can be customized by an application developer. This skeleton is generally represented by a set of abstract classes. The abstract classes define the core functionality of the framework, which also contains a set of concrete classes that provide a prototype application introduced for completeness. The main characteristics of frameworks are their provision of high level abstraction; in contrast to an application that provides a concrete solution to a concrete problem, a framework is intended to provide a generic solution for a set of related problems. Plus, a framework captures the programming expertise: necessary to solve a particular class of problems. Programmers purchase or reuse frameworks to obtain such problem-solving expertise without having to develop it independently.

Such advantages are exploited in Scherp and Boll (2004) where a generic java-based software framework is developed to support personalized (mobile) multimedia applications for travel and tourism. This contribution provides an efficient, simpler, and cheaper development platform of personalized (mobile) multimedia applications.

The Sesame environment (Coffland & Pimentel, 2003) is another software framework built for the purpose of modeling and simulating heterogeneous embedded multimedia systems.

Even if software frameworks are considered as an independent software technique, they are very often used to leverage middleware development and to realize the layered approach.

Design Patterns

Design patterns are proven design solutions to recurring problems in software engineering. Patterns are the result of developers' experience in

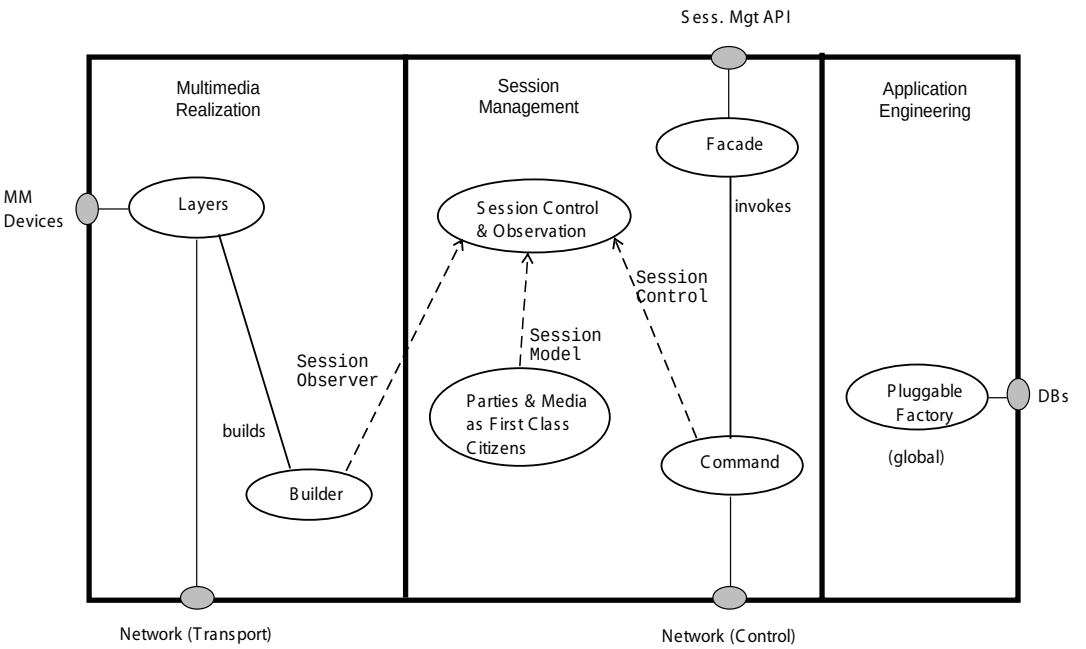
solving a specific problem like request to events, GUIs, and on-demand objects creation. In object-oriented technologies, a design pattern is represented by a specific organization of classes and relationships that may be implemented using any object-oriented language. The book by Gamma, Helm, Johnson, and Vlissides (1995) is an anchor reference for design patterns. It establishes (a) the four essential elements of a pattern, namely, the pattern name, the problem, the solution and the consequences and (b) a preliminary catalog gathering a set of general purposes patterns. Later, many application-specific software patterns have been proposed such as in multimedia, distributed environments and security.

Compared to software frameworks discussed earlier, patterns can be considered as micro software frameworks; a partial program for a problem domain. They are generally used as building blocks for larger software frameworks.

MediaBuilder (Van den Broecke & Coplien, 2001) is one of most successful initiatives to pattern-oriented architectures for mobile multimedia applications. MediaBuilder is a services platform that enables real-time multimedia communication (i.e., audio, video, and data) between end-user PC's. It supports value-added services such as multimedia conferencing, telelearning, and teleconsultation, which allows end-users at different locations to efficiently work together over long distances. The software architecture is a set of patterns combined together to support session management, application protocols, and multimedia devices. Figure 3 summarizes the main patterns brought into play in order to determine the basic behavior of MediaBuilder. Each pattern belongs to one of the functional areas, namely; multimedia realization, session management, and application engineering.

The use of design patterns for mobile multimedia is driven by the desire to provide a powerful tool for structuring, documenting, and communicating the complex software architecture. They also allow the use of a standard language making the overall

Figure 3. Architecture of MediaBuilder patterns (Van den Broecke & Coplien, 2001)



architecture of the multimedia application easier to understand, extend, and maintain.

The synergy of the three techniques previously discussed is depicted in Schmidt and Buschmann (2003). This synergy contributes to mobile multimedia development by providing high quality software architectures.

CHALLENGES OF MOBILE MULTIMEDIA SOFTWARE ENGINEERING

While system support for multimedia applications has been seriously investigated for several years now, the software engineering community has not yet reached a deep understanding of the impacts of "mobility" for multimedia systems. The latter has additional requirements compared to traditional multimedia applications. These requirements are linked to the versatility of the location of consumers and the diversity of their preferences. In the following, we address the main research areas that must be investigated by the software engineering community in supporting the development of mobile multimedia applications. These areas are not orthogonal. It means that same or similar research items and issues appear in more than one research area. We have divided the research space into four key research areas: (1) mobility, (2) context-awareness, and (3) real-time embedded multimedia systems.

Mobility

For the purpose previously discussed, the first trail to investigate is obviously "mobility." It is viewed by Roman, Picco, and Murphy (2000) to be the study of systems in which computational components may change location. In their roadmap paper on software engineering for mobility, they approach this issue from multiple views including models, algorithms, applications, and middleware. The middleware approach is generally adopted for the purpose of hiding hardware heterogeneity of mobile platforms and to provide an abstraction layer on top of specific APIs for handling multimedia content.

However, current investigations of software engineering for mobility argue that there is a lack of well-confirmed tools and techniques.

Context-Awareness

Context has been considered in different fields of computer science, including natural language processing, machine learning, computer vision, decision support, information retrieval, pervasive computing, and more recently computer security. By analogy to human reasoning, the goal behind considering context is to add adaptability and effective decision-making.

In general mobile applications, context becomes a predominant element. It is identified as any information that can be used to characterize the situation of an entity. Where an entity is a person, or object that is considered relevant to the interaction between a user and an application, including the user and application themselves (Dey, 2001). Context is heavily used for e-services personalization according to consumers' preferences and needs and for providing fine-grained access control to these e-services. In the domain of mobile multimedia, this rule is still valid. Indeed, multimedia content whether this content is static (e.g., jpeg, txt), pre-stored (e.g., 3gp, mp4) or live, must be tuned according to the context of use. Mobile cinema (Pan, Kastner, Crowe, & Davenport, 2002) is an example, it is of great interest to health, tourism, and entertainment. Mobile cinema relies on broadband wireless networks and on spatial sensing such as GPS or infrared in order to provide mobile stories to handled devices (e.g., PDAs). Mobile stories are composed of media sequences collected from media spots placed in the physical location. These sequences are continually rearranged in order to form a whole narrative. Context used to assemble

mobile stories are mainly time and location but can be extended to include information collected using bio-sensors and history data.

Multimedia mobile service (MMS) is a brand new technology in the market but rapidly becomes a very popular technique used to exchange pictorial information with audio and text between mobile phones and different services. Häkkilä and Mäntyjärvi (2004) propose a model for the combination of location—as context—with MMS for the provision of adaptive types of MM messages. In their study, the authors explore user experiences on combining location sensitive mobile phone applications and multimedia messaging to novel type of MMS functionality. As they state in Häkkilä & Mäntyjärvi (2004), the selected message categories under investigation were presence, reminder, and notification (public and private), which were selected as they were seen to provide a representing sample of potentially useful and realistic location related messaging applications.

Coming back to the software perspective and based on a review of current context-aware applications, Ghita Kouadri Mostéfaoui (2004) points up to the lack of reusable architectures/mechanisms for managing contextual information (i.e., discovery, gathering, and modeling). She states that most of the existing architectures are built in an ad hoc manner with the sole desire to obtain a working system. As a consequence, context acquisition is highly tied up with the remaining infrastructure leading to systems that are difficult to adapt and to reuse.

It is clear that context-awareness constitute a primordial element for providing adaptive multimedia content to mobile devices. Even if currently, location is the most used source of contextual information, many other types can be included such users' preferences. Thus, we argue that leveraging mobile multimedia software is tied up with the improvement of software engineering for context-awareness. The latter constitutes one of the trails that should be considered for the development of adaptive mobile multimedia applications.

Real-Time Embedded Multimedia Systems

Real-time synchronization is an intrinsic element in multimedia systems. This ability requires handling events quickly and in some cases to respond within specified times. Real-time software design relies on specific programming languages in order to ensure that deadlines of system response are met. Ada is an example language; however, for ensuring a better performance, most real-time systems are implemented using the assembler language. The mobility of multimedia applications introduces additional issues in handling time constraints. Such issues are management of large amount of data needed for audio and video streams. In Oh and Ha (2002), the authors present a solution to this problem by relying on code synthesis techniques. Their approach relies on buffer sharing. Another issue in real-time mobile multimedia development is software reusability. Succi, Benedicenti, Uhrik, Vernazza, and Valerio (2000) point to the high importance of reusability for the rapid development of multimedia applications by reducing development time and cost. The authors argue that reuse techniques are not accepted as a systematic part of the development process, and propose a reusable library for multimedia, network-distributed software entities.

Software engineering real-time systems still present many issues to tackle. The main ones are surveyed by Kopetz (2000) who states that the most dramatic changes will be in the fields of composable architectures and systematic validation of distributed fault-tolerant real-time systems.

Software engineering mobile multimedia embraces all these domains and therefore claims for accurate merging of their respective techniques and methodologies since the early phases of the software development process.

Bridging the Gap Between Software Engineering and Mobile Multimedia

Different software engineering techniques have been adopted to cope with the complexity of designing mobile multimedia software. Selecting the "best" technique is a typical choice to be made at the early stage of the software design phase. Based on the study we presented earlier, we argue that even if the research community has been aware of the advantages of software engineering for multimedia, mobility of such applications is not yet considered at its own right. As a result, the field is still lacking a systematic approach for specifying, modeling and designing, mobile multimedia software. In the following, we stress a preliminary set of guidelines for the aim to bridging the gap between software engineering and mobile multimedia.

- The mobile multimedia software engineering challenges lie in devising notations, modeling techniques, and software artifact that realize the requirements of mobile multimedia applications including mobility, context-awareness, and real-time processing
- The software engineering research can contribute to the further development of mobile multimedia by proposing development tools that leverage the rapid design and implementation of multimedia components including voice, image, and video
- Training multimedia developers to the new software engineering techniques and methodologies allows for the rapid detection of specific tools that leverage the advance of mobile multimedia
- Finally, a community specializing in software engineering mobile multimedia should be established in order to (1) gather such efforts (e.g., design patterns for mobile multimedia) and (2) provide a concise guide for multimedia developers (3) to agree on standards for multimedia middleware, frameworks and reusable multimedia components

CONCLUSION

In this chapter, we highlighted the evolving role of software engineering for mobile multimedia development and discussed some of the opportunities open to the software engineering community in helping shape the success of the mobile multimedia industry. We argue that a systematic reliance on software engineering methodologies since the early stages of the development cycle is one of the most boosting factors of the mobile multimedia domain. Developers should be directed to use reuse techniques in order to reduce maintenance costs and produce high-quality software even if the development phase takes longer.

KEY TERMS

Context-Awareness: Context awareness is a term from computer science that is used for devices that have information about the circumstances under which they operate and can react accordingly.

Design Patterns: Design patterns are standard solutions to common problems in software design.

Embedded Systems: An embedded system is a special-purpose computer system, which is completely encapsulated by the device it controls.

Middleware: Middleware is software that can significantly increase reuse by providing readily usable, standard solutions to common programming tasks, such as persistent storage, (de)marshalling, message buffering and queuing, request de-multiplexing, and concurrency control.

Real-Time Systems: Hardware and software systems that are subject to constraints in time. In particular, they are systems that are subject to deadlines from event to system response.

Software Engineering: Software engineering is a well-established discipline that groups together a set of techniques and methodologies for improving software quality and structuring the development process.

Software Frameworks: Software frameworks are reusable foundations that can be used in the construction of customized applications.

This work was previously published in Handbook of Research on Mobile Multimedia, edited by I. K. Ibrahim, pp. 251-265, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Section 5

Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of multimedia technologies around the world. Chapters introducing this section analyze multimedia as a vehicle for cultural transmission and language, while later contributions offer an extensive analysis of educational multimedia. The inquiries and methods presented in this section offer insight into the integration of multimedia technologies in social and organizational settings while also emphasizing potential areas of study within the discipline.

Chapter 5.1
Multimedia as a Cross-Channel for Cultures and Languages

Ramesh C. Sharma
Indira Gandhi National Open University, India

Sanjaya Mishra
Indira Gandhi National Open University, India

INTRODUCTION

Around the world many communities have been constantly struggling to maintain their customs, traditions and language. Many communities have been on the move from place to place due to various factors of social change, such as war, search of food, land, and climatic calamities. Such forces have given rise to different cultures and languages through fusion or the creation of new cultures. The cultures not only exist within nationalities and ethnic groups, but also within communities, organizations and other systems. A language is an integral component of cultural identification (Rogers & Steinfatt, 1999). Matsumoto (1996, p. 16) defined culture as, "the set of attitudes, values, beliefs, and behaviours shared by a group of people, but different for each individual, communicated from one generation to the next." A culture is dynamic in nature; if static, it will cease or lose its identity in due course of time. Cultural values are affected and reinforced by languages. A language is a representation of a different way of thinking as well as a different way of speaking. Languages have significant influence on the cognition (Gudykunst & Asante, 1989; Pincas, 2001).

WHAT IS MULTIMEDIA?

Recent advances in information and communication technologies (ICTs) have resulted in the integration of the basic multimedia technology with the personal computer. Thus now it is possible to offer pedagogically useful services through this interactive medium (Peters, 2003). In its simplest form multimedia can be defined as, "an integration of multiple media elements (audio, video, graphics, text, animation etc.) into one synergetic and symbiotic whole that results in more benefits for the end user than any one of the media elements

can provide individually" (Reddi, 2003, p. 3). One of the basic advantages of multimedia tools lies in presenting learning materials in multiple (i.e. audio, visual and textual) formats. Jacobson and Spiro (1995) argued that complex information is learned more effectively if the learning experiences are presented in multimedia formats. Learners' interests and motivations can be increased by the integration of rich and dynamic multimedia into the learning experiences (Smith & Jones, 1989). Student learning can also be effectively increased by combining multi-modal dynamic simulations with audio, when the audio media is an integral part of information to be learned (Moreno & Mayer, 2000). Hoyer (1999) experienced effective teaching, research, counseling and learner support when interactive multimedia modules are integrated with services such as teleconferencing.

Multimedia has many uses in education as an instructional tool and as a product development tool. The booster factor to the development of multimedia technologies has been its pedagogical implications and effects on teaching and learning practices. Incorporating multimedia elements supports a paradigm shift in the pedagogy. The traditional teacher-centered or technology-centered approach of multimedia instruction has been supplanted by the constructivist learner-centered approach (Relan & Gillani, 1997; LeFoe, 1998; Richards & Nason, 1999; Tearle, Dillon & Davis, 1999; Abbey, 2000). Multimedia applications have created new opportunities for instructional designers to present instruction through dynamic integration of words, static and dynamic graphics and verbal information. Multimedia technologies have been found to be useful in enhancing learning and learner satisfaction, and increasing the visibility and appeal of existing programs. These technologies also support portability, modularity, visualization, efficiency in instructional design, and learning consistency (Oberlin, 1996; Hede, 2002; Yildirim, Ozden, & Aksu, 2001).

MULTIMEDIA IN CULTURAL CONTEXT

Communities and societies over time have adopted different measures for the preservation, transmission and advancement of their languages and cultural heritages. Education and communication are two effective measures. Owing to the dynamism of communities, the educational sector has been constantly witnessing structural, pedagogical, procedural and technological changes. These changes are inevitable. Increase in the demand for learning and increase in socio-cultural infusion has resulted in increasing pressure on educational providers for new ways of delivering instructional programs. The world has expanded and contracted in terms of population and space respectively. As a direct consequence, different cultures and languages have realized the increasing importance of having a dynamic and vibrant means of communication in place, which can help them maintain their identity, and observe progress in a multicultural learning environment. Odasz (n.d.) states, "The world's diverse cultures jointly represent the full cultural genome of humankind's search for individual and group identity and meaning" and exert pressure to record this important "shared story of humankind". The sooner actions are taken to save the cultural knowledge of our ancestors, the better will be, as it is feared that nearly half of the world 6000 languages may disappear in one lifetime. Odasz (n.d.) recommends, "The vast cultural knowledge of our elders must be recorded via multimedia storytelling for preservation while they (our elders) are still with us."

UNESCO has also been very concerned about the preservation of cultures of indigenous people (around 350 million individuals in more than 70 countries) representing more than 5000 languages and cultures. The cultural heritage of some of them is nearing extinction, if no action is taken to save them (http://portal.unesco.org/culture/en/ev.php-URL_ID=2946&URL_DO=DO_TOPIC&URL_

SECTION=201.html). On 10 December 1994, the United Nations General Assembly declared the *International Decade of the World's Indigenous People*. To mark the significance of cultural diversity of indigenous populations, the *International Day of the World's Indigenous Peoples* is celebrated every year on 9 August.

The transfer of knowledge from one region to another or from one generation to another requires educational or learning material understandable to many. A Universal Networking Language (UNL) is being developed by the United Nations University. The UNL is the global lingua franca of computers and will be providing services for any pair of languages from over 180 countries. Yoshii, Katada, Alsadeqi, and Zhang (2003) found that although the content on the Internet is growing, much of it is written in English, rendering it unsuitable for those who do not understand English. If they wish to access that content they are made to learn English, and thus for such non-English speaking people, the language learnt sometimes is inappropriate. Tools have been developed to translate material from one language to other, but such translation may not be free from errors and may misrepresent the actual sense of context, and may also suffer from cultural imperialism (Phillipson, 2002). Thus it becomes very pertinent to keep certain issues related to cultural sensitivity and languages in mind while developing multimedia content.

CULTURAL SENSITIVITY FOR MULTIMEDIA DESIGNING

Pruitt-Mentle (2003) revealed that people with different cultural backgrounds have different expectations and attitudes towards educational software. And educational software developed in one country may suffer from cultural biases. To overcome cross-cultural barriers of verbal and non-verbal communication or symbols as practiced in a particular country, Pruitt-Mentle recommended the learning of such cultural differences while designing multimedia learning resources, rather than to deny or ignore such diversity.

Since a variety of personnel are involved in instructional design, Gunawardena, Wilson and Nolla (2003) advocated understanding of the cultures of all involved, such as course designers, teachers and students. Everyone has his own background culture and attitudes and societal norms on the instructional product. An essential concern while designing multimedia applications for diverse community groups is to be aware of cultural influences. This creates the need to develop cultural sensitivity and awareness among designers and instructors (Powell, 1997; Reeves, 1997). Chen, Mashhadi, Ang and Harkrider (1999) suggested, "the interface designer must be aware how different cultures will respond to issues of the layout of the graphical interface, image, symbols, colour and sound, impressing that culture itself cannot be objectified unproblematically as just another factor to be programmed into a learning course" (p. 220). The multimedia designers, while designing for a diverse community, must be flexible about a variety of presentation formats to accommodate cross-cultural differences (Collis, 1999).

Other issues which may arise while developing culturally sensitive instructional material are values and attitudes, ethical perspectives diversity within groups, historical perspectives, socio-economic perspectives, social roles, social networks, learner expectations, learning styles, and opportunities for interactions (Dunn & Griggs, 1995; Powell, 1997a, 1997b; Collis, 1999; Mcloughlin, 1999; Reeves, 1997). Gjedde (2005) suggested that issues such as social and cultural backgrounds and gender-specific interests, must be considered when developing meaningful content and creating narrative multimedia learning environments.

MEETING THE CHALLENGE OF CULTURES AND LANGUAGES THROUGH MULTIMEDIA

Mouafo and Miller (2002) found the use of digital and web-based multimedia cartography very useful in injecting new life into archived data such as old paper maps and photographs. Mouafo and Miller presented the results of a "The Historical Evolution of Iqaluit" mapping project showing the changes in time and space in the city over the past 50 years (1948-1998). (Iqaluit, is the upcoming capital city of the new territory of Nunavut in Northern Canada). Such projects have high significance to the culture, education, and tourism as well as enhancing city planning and development. Multimedia maps have many advantages—they enable a dynamic and multifaceted representation of space and time, superior map production and dissemination, improved information and knowledge transfer, and greater map accessibility (Balram & Dragicevic, 2005).

UCLA has undertaken the development of Multimedia Research Projects in areas like Anthropology, Chemistry/Biochemistry, Computer Science, Dance, Dentistry, Education, Electrical Engineering, Germanic Languages, Linguistics, Medicine, Music Composition, Musicology/Performance, Nursing, Physics, Psychology, Public Policy, Slavic Languages and Literatures, Theater, Film and Television, University Elementary School, University Extension, and Visual Library. (See details at http://www.research.ucla.edu/media.htm). These projects cover a vast array of human knowledge and activity. Some projects related to cultures and languages are:

- *Culture and Communication* (http://www.research.ucla.edu/mmedia/anthro.htm#anthro2),
- *Educational Multimedia on Pacific Studies* (http://www.research.ucla.edu/mmedia/pacrim.htm#anchor435555),
- *Crosslinguistic Research Project* (http://www.humnet.ucla.edu/humnet/al/clrl/crphome.html) for Applied Linguistics,
- *Bulgarian Traditional Music on CD-ROM* (http://www.research.ucla.edu/mmedia/ethno.htm)
- *World Music Navigator* (http://www.research.ucla.edu/mmedia/ethno.htm#anchor6071659) developing under Ethnomusicology,
- *Comparative Court Cultures In Cross-Cultural Perspective* (http://www.research.ucla. edu/mmedia/cmrs.htm) developed by The Center for Medieval and Renaissance Studies.

The UCLA School of Dentistry has developed a unique "*Preceptorship (Specialty Training) Program*" (http://www.dent.ucla.edu/ce/in-person/precep/index.html) targeted at foreign-educated dentists all over the world. This program is delivered via the Internet and aims to enrich the educational experiences of dentists in a certain specialty.

Multimedia applications have also addressed social causes and concerns. One of these projects is a multimedia AIDS prevention project "AIDS: Interactive Situations" that has been undertaken jointly by research teams from the co-operative group, CLAPS, of Pordenone, Italy, and the University of Barcelona (ICE), Spain (Illera, 2005). The cultural and linguistic differences affect the education of differently abled students in classroom. Allen (1994) and Schildroth and Hotto (1996) studied the problems of deaf children from Spanish-speaking homes in the US towards learning English and were found to perform at lower levels from their Caucasian deaf peers. If such students come from different cultures or religion, they may use different sign languages. Such a situation may create problems for students learning subjects in a particular language. To promote the Mexican-American heritage of such deaf students and to accommodate their cultural and language needs, multimedia labs have been

established and multimedia stories on CD-ROMs have been produced (Pollar, 1993; Hernandez, 1994).

MULTIMEDIA IN A FOREIGN LANGUAGE INSTRUCTIONAL CONTEXT

Many cultures (like rural folk in Rajasthan State in India) use narration and story telling as a way of passing on the past to the present generation. Narration enables the learners to participate in the process and becomes the core of an experiential and contextual approach to learning. A project in the Danish Language and Art curriculum, called, "The Narrative Universes of Children" and "Narrative in interactive Web-based learning environments" enables children to identify with the characters and situations in the narratives (Gjedde, 2005). Multimedia materials may even provide the opportunity to mimic the patterns of traditional acquisition of native language and cultural competence, which in many cultures have formerly relied on repeated observation, playful pursuit and accompanying (more or less informal) explanation instead of abstract, decontextualized texts (Dürr, 1998).

LeLoup and Ponterio (1998) listed some of the multimedia applications (e.g., audio, digitized video) on the Internet using multimedia in a Foreign Language instructional context. Some of these applications are used for less- commonly-taught (LCT) languages and offer to the viewer or learner expression of native speaker pronunciation, cultural topics and references, and techniques of mastering difficult non-Roman scripts. Here is a listing of some of these sites:

- http://www.cortland.edu/flteach/civ/ deals with French instruction;
- http://web.uvic.ca/german/149/ offers lessons for beginning German students;
- http://carla.acad.umn.edu/vpa/hebrew/intro.html provides interactive lessons in Hebrew;
- http://carla.acad.umn.edu/vpa/India/exercises.html has applications in basic Hindi language courses;
- http://www.stanford.edu/~muratha/ is useful for Swahili classes and narrates cultural stories;
- http://www.fix.co.jp/kabuki/kabuki-j.html offers many vocal and musical sounds of traditional Kabuki; and
- http://www.wavefront.com/~swithee/dictionary/welcome.html contains Russian dictionary with sounds and still images.

Multimedia applications have also been developed for a flexible, effective and efficient mode of delivery for learning and teaching Chinese, especially Chinese characters. These applications have attracted a good response, acknowledgement and better inclination of students towards multimedia mode of delivery than traditional mode of learning Chinese characters. The difficulties in learning Chinese characters can be easily tackled through multimedia; Wang (1999) found that multimedia raised learners' motivation and self-esteem, satisfying individual differences, abilities and learning styles.

CONCLUSION

The swift developments in multimedia technology and products have revolutionized the ways of teaching and learning across different cultures. The content generated with multimedia applications act as a vehicle for knowledge that is well-suited to many cultures and languages across the globe. The new multimedia tools provide great opportunities for the preservation, expression, strengthening and dissemination of cultural identities and languages. The various projects, products, tools and Internet sites discussed above truly reflect the unparalleled capabilities of multi-

media technologies towards acquiring, mastering and advancing the past heritage to different platforms. These tools can be used as self-study aids, training tools, traditional narrative resources, and social and interpersonal communication channels. Research has shown that learning becomes a more effective and pleasant process through the use of interactive multimedia. Multimedia has excellent scope in educational, health, agriculture, social, scientific, engineering, history and geographical areas. Multiple representation, multilingualism and multimodal dialogues infuse interactivity, accessibility, understanding, and knowledge extraction and summarization to the cause of many cultures and languages.

KEY TERMS

Culture: The ideals, values, symbols and behaviors of human societies that create a distinctive identification.

Language: A means of verbal and non-verbal communication of thoughts and ways of speaking.

Multimedia: Integration of several media, such as text, audio, video, animation, etc.

Chapter 5.2
Developing Culturally Inclusive Educational Multimedia in the South Pacific

Christopher Robbins
Rhode Island School of Design, USA
The University of the South Pacific, Fiji

ABSTRACT

This chapter explores how educational technology can be developed according to indigenous learning approaches of the South Pacific. It is based on an expansive research and development project conducted 2003-2004 at The University of the South Pacific (USP). After an introduction to several aspects of indigenous South Pacific learning approaches and their usage in the formal learning sector, I make several recommendations for instructional technology design based on these principles, illustrated with examples of educational technology projects that apply these recommendations. Specifically, we follow educational multimedia efforts at USP that enable learning in wholes, encourage observation and imitation and utilize vernacular metaphors and languages. This includes recommendations for interface design, interaction design and decentralized content localization.

INTRODUCTION

Information technology plays a vital but contentious role in tertiary education in the South Pacific. Although many students must rely on information technology for higher education, there are concerns regarding the intrinsic cultural biases of, and unbalanced access to, educational technology in the region (Matthewson, 1994; Thaman, 1997; Va'a, 1997; Wah, 1997). Approximately half of the 15,000 students of The University of the South Pacific (USP) study through USP's Distance and Flexible Learning (DFL) Centers, a network of mini-campuses in 12 island-nations (Cook Islands, Fiji, Kiribati, Marshall Islands, Nauru, Niue, Samoa, Solomon Islands, Tokelau, Tonga, Tuvalu and Vanuatu) linked through VSAT satellite (USP DFL Unit, 2004). These students negotiate audio and video conferences, Web-based group activities, interactive CD-ROMs, video broadcasts of lectures, email, faxes and even CB

radio as they communicate with their teachers and fellow students.

While educational technology offers distance students a higher degree of interaction with their educational materials, lecturers and fellow students, it can also introduce additional cultural biases into their already imported education system. The cultural gaps between USP's formal education system and the diverse South Pacific cultures of USP's staff and students has been widely documented (Lockwood, Roberts, & Williams, 1998; Thaman, 1997; Va'a, 1997, 2000; Wah, 1997). Closing these gaps through culturally inclusive curricula and pedagogy has become an institutional priority. Recently, the University's focus on culturally relevant pedagogy has broadened to include the instructional design of educational technology.

As part of this initiative, The University of the South Pacific Media Centre, with funding from the Japan International Cooperation Agency (JICA), completed a project that examined how educational multimedia can be designed according to the learning approaches of the South Pacific. In the study (Robbins, 2004), we captured the views of Pacific educationists through a series of interviews and a review of academic literature covering indigenous pedagogy in the South Pacific. We conducted interviews, employed questionnaires and usability tests with staff and students from the 12 member-nations of USP to find applications of regional learning approaches to the development of educational technology and built an educational CD-ROM to audit and illustrate the findings.

In this chapter I outline several recommendations and applications of these findings, focusing on how educational multimedia can be made culturally relevant to the South Pacific.

The goal of this chapter is not only to enable technological fluency by helping developers create educational multimedia designed specifically for the region, but also to ensure that the technology promotes indigenous approaches and values, rather than submerging them under dominant technological hegemonies.

PEDAGOGIC FOCUSES FOR EDUCATIONAL TECHNOLOGY DEVELOPERS IN THE SOUTH PACIFIC

This chapter concentrates on three regional pedagogic focuses relevant to educational technology in the region:

1. Enable learning in wholes (Thaman, 1992; Yorston, 2002);
2. Encourage observation and imitation (Lima, 2003; Pagram, Fetherston, & Rabbitt, 2000; Taufe'ulungaki, 2003; Thaman, 1999; Yorston, 2002); and
3. Utilize vernacular metaphors and languages (Afamasaga, 2002; Pagram, Fetherston, & Rabbitt, 2000; Taafaki, 2001; Taufe'ulungaki, 2003; UNESCO, 1992).

Enabling learning in wholes, or preserving "the big in the small," arises time and again as a key component of South Pacific learning approaches (Mel, 2001; Harris, 1992; Thaman, 1992; Yorston, 2002). The key concept is that rather than segmenting learning activities into distinct conceptual units, ideas are approached as they can be applied within the context of larger tasks (Thaman, 1992; Yorston, 2002). In other words, rather than master each step consecutively, learners witness and then imitate the whole, attaining the desired goal through trial and error (Mel, 2001). To preserve the whole, complex activities are tackled as "successive approximations" of the final product rather than as "sequenced parts" (Harris, 1992, p. 38). For example, in learning a musical piece using this method, a band would play the entire piece through until they had mastered it, as opposed to repeating individual refrains.

A nuance of learning in wholes is that in each step, the focus is on the specific context of the task or idea and its relevance to the broader goal, as opposed to working from generalizations towards instances of universals (Thaman, 2003; Va'a, 1997).

In educational technology, this approach has ramifications for information architecture and interface design, suggesting navigation processes that are more task than concept-focused, and content-display that continues to present the wider context while students explore details.

Closely related to the concept of learning in wholes is the process of observation and imitation, as both approaches originate from task-based learning exercises applied in "real world" settings. However, while learning in wholes translates well from traditional contexts to formal education settings, observation and imitation can manifest itself less desirably as rote memorization and surface learning (Landbeck & Mugler, 1994). Tying observation and imitation activities to application rather than memorization can encourage deep learning (Landbeck & Mugler, 1994). In other words, showing how a concept can be applied to something the student already knows can situate the knowledge more deeply than having students memorize sets of tasks or terms.

Teaching from students' own cultural contexts can be difficult with a population as diverse and distributed as that served by USP, and is further confounded by the colonial history and post-colonial legacy of formal education in the region (Petaia, 1981; Thaman, 2000b, 2003; Wah, 1997). Most textbooks used at USP are published in Europe and North America, and utilize examples from the cultures in which the books are produced (Thaman, 2000a). Despite efforts to create culturally relevant learning materials at USP, it can be incredibly difficult to choose examples and metaphors that make sense in all 12 countries served by the University:

> *Some of the course writers only use examples from the countries they know. If you look at sourcebooks, most use examples from Fiji and Samoa — a staff-member at the USP Solomon Island DFL Centre.* (Robbins, 2004, p. 29)

> *The exam paper had to do with kava. It was like double-dutch to us… Most of the examples are very Fijian. We don't have veggie markets. We don't have military management. I have to pick something we can identify with — a staff-member at the USP Nauru DFL Centre.* (Robbins, 2004, p. 29)

In addition to local metaphors, there is also a need for local languages in educational materials. Vernacular languages play a vital role in this officially English-speaking University. As a lecturer at the Samoa Campus confessed, "after class, when there are no other English-speaking students around, they ask me to explain in Samoan" (Robbins, 2004, p. 16). A program assistant's comments at the Tuvalu DFL Centre clarified, "all students understand English, it's just when it comes to tutoring, or when a point needs to be understood subtly, the students and the tutors prefer to exchange in the local language" (Robbins, 2004, p. 16).

Regional research has shown that using vernacular language aids comprehension (Pagram, Fetherston, & Rabbitt, 2000; Taafaki, 2001; Taufe'ulungaki, 2003) and deeper learning (Kalolo, 2002) where English alone can fail, and is also important for purposes of cultural preservation (Afamasaga, 2002; Sami, 2004; Taufe'ulungaki, 2003; Veramu, 2004).

Taken together, these pedagogic foci indicate that educational technology in the South Pacific should utilize vernacular metaphors, examples and languages, and should be presented in a way that enables learning in wholes using activities that rely on observation and imitation.

APPLICATIONS OF INDIGENOUS LEARNING APPROACHES TO EDUCATIONAL TECHNOLOGY IN THE SOUTH PACIFIC

In this section, I discuss how the aspects of South Pacific learning approaches outlined earlier can be applied to the development of culturally inclusive educational multimedia. Specifically, I explore how interventions at the following design levels can help achieve our pedagogic goals:

1. **Interface level:** enable learning in wholes;
2. **Interaction level:** encourage observation and imitation; and
3. **Content level:** utilize vernacular metaphors and languages.

Interface Level: Enable Learning in Wholes

The solutions we have created to enable learning in wholes are primarily interface-based, maintaining the big picture while focusing students on specifics. I discovered one very simple way to preserve "the big in the small" while looking for something else entirely. As part of our 2003-2004 study (Robbins, 2004), we asked 155 students of USP to choose between two Web designs (Figure 1). The goal was to determine whether the students would feel more comfortable with contextual, inline navigation (links within the body of the text), or with a separate menu listing the links apart from the body. I expected students to prefer the simpler, inline approach (labeled "L"), as this is closer to the layout of books, and so would be more familiar to them than the Web-derived navigation menu. However, my hunch was proven unequivocally wrong: 93% of the students preferred the menu navigation, labelled "O" (X^2 (2, N = 155) = 250.90 $p < 0.0001$). Students appreciated that the separate menu neatly summarized the longer text, and allowed them to jump directly to points of interest without losing their place.

A graphical corollary involves presenting concepts through "layers of simplicity" that offer increasing levels of detail to the students without muddying the overall purpose of the graphics. In other words, the basic lesson or overall theme of the image is always clear, even when students have drilled into details of the graphic or animation. For example, in Figure 2 we present the student with a simple initial layer of information (arrows showing immigration patterns), augmented with deeper layers of information (descriptions of archaeological remnants at different sites or related stories from regional oral histories) that the student can access by clicking sections of the map/timeline with his or her mouse.

Interaction Level: Encourage Observation and Imitation

While preserving the whole plays a role in determining the organization of content in the interface, observation and imitation have applications when designing the deeper interactivity and functionality of an educational technology project. Designing these interactions around observation and imitation enables students to act on instructions within the learning interface. For instance, in Figure 3, instructions are overlaid on the active interface, rather than being provided in separate instruction screens, so that students seeking help are shown exactly what to do, where to click and how to do it, rather than merely being provided with instructions.

By programming timers that automatically demonstrate the options for the user after a period of inactivity, this same approach can be used to help students with a tendency to "freeze" when confused, and has many applications to lab simulations.

Figure 1. Navigation preference (Robbins, 2004, used with permission)

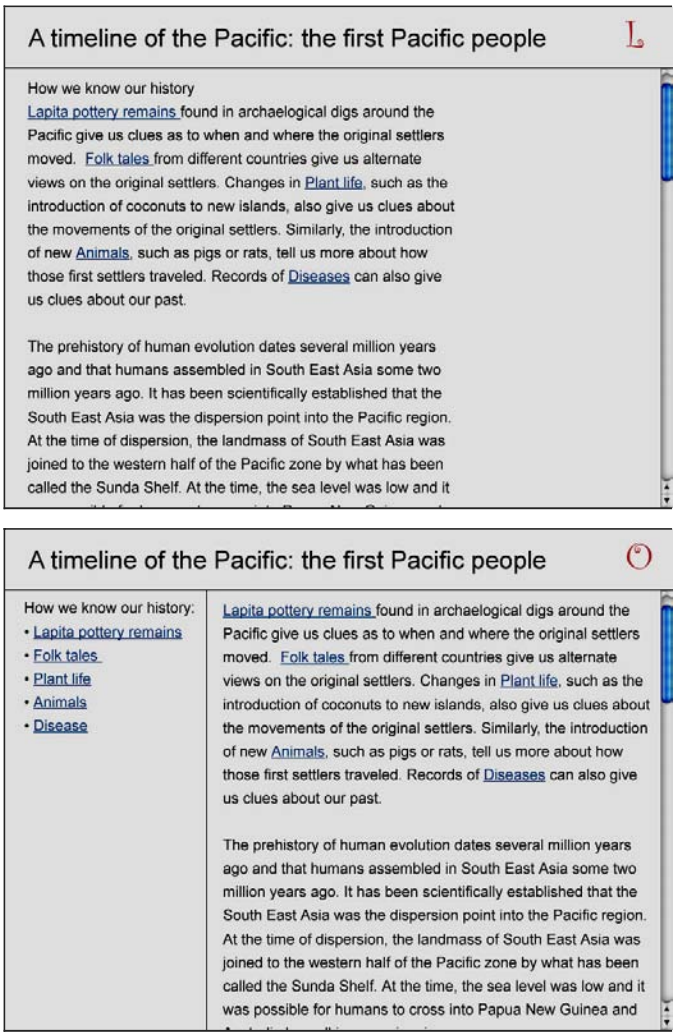

Figure 2. Using layers of simplicity on a map/timeline to show immigration patterns into the South Pacific (Robbins, 2004, used with permission)

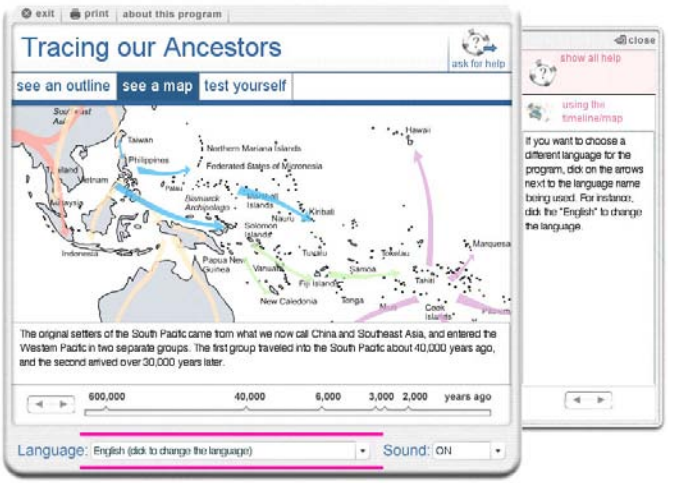
Figure 3. Instructions are paired with an overlay showing how to act on the instructions within the interface itself (Robbins, 2004, used with permission)



Content Level: Utilize Vernacular Metaphors and Languages

The most obvious way that educational technology can be made culturally inclusive is by including the cultures of students and teachers in the educational content. This is true anywhere in the world, but is a particular focus at USP because of the wide gaps between the cultures of the educational institution, students, teachers and educational technology developers.

As USP caters to 12 distinct island-nations, providing truly local illustrations for every concept is incredibly difficult. However, by designing educational multimedia so that teachers and students can provide cultural context themselves, educational technology developers can create flexible toolsets that decentralize the contextualization process.

One such solution is the virtual peer, which uses regional examples as "seed-questions" to encourage students to contribute their own explanations. In Figure 4, peers representing different cultures in the South Pacific discuss aspects of the Internet using metaphors from their home countries. Clicking the "show me" button brings up an animation, illustration or audio clip, so the interface is not dominated by text.

To further situate the learning to the student's own circumstances, the student is asked to make his or her own descriptions of the concept (Figure 5). These answers are saved on the computer for future iterations of the program, allowing other students to view each other's perspectives.

Another approach to creating flexible educational multimedia relies on the file structure rather than the interface. For instance, in order to create multilingual and multicultural educational multimedia at USP, we have employed an open-source, three-tier file structure to help staff and students customize their learning materials themselves. Separating the core multimedia from all supporting image, text and audio files makes these updates easier to achieve. Figure 6 shows how this approach can be used to create an open framework for multilingual multimedia. Each language is given its own text file so that students and teachers need only make edits to existing text files to add additional languages and metaphors. The language files are inserted into the educational multimedia at runtime so that the materials are flexible and current.

Figure 4. A virtual peer gives his or her own descriptions of the concepts in local terms (Robbins, 2004, used with permission)

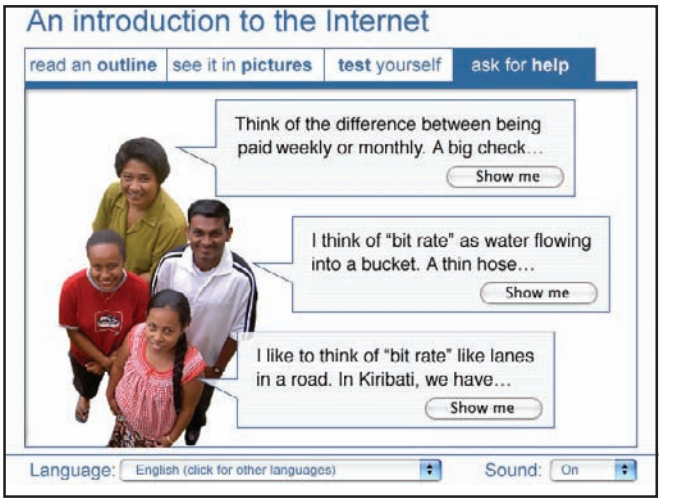


Figure 5. The student is asked to make his or her own metaphors to describe streaming media (Robbins, 2004, used with permission)

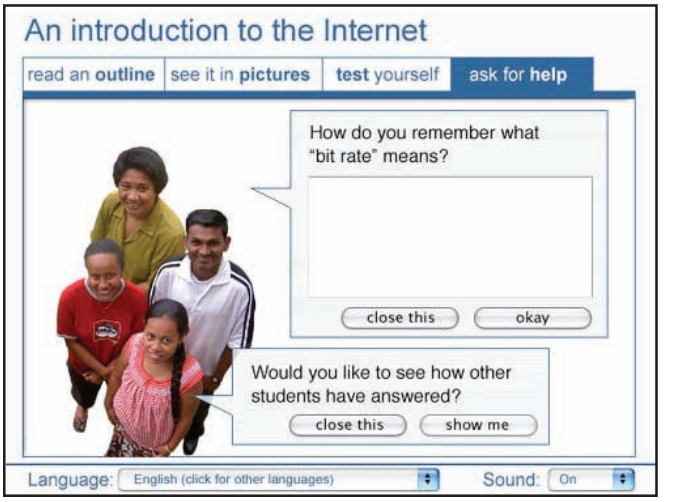
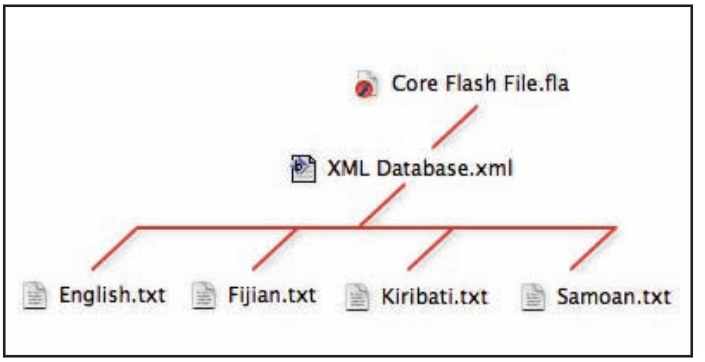


An additional benefit of the three-tier file structure is that presenting the images, audio files, videos and animations separately encourages their re-use in other media, aiding accessibility as well as customization of the media. The approach can also make the separate elements of a multimedia project (text, images, video and audio) available for re-use in other projects and media, along the lines of learning objects in object-oriented instructional design (Ahern & Van Cleave, 2002; Parrish, 2004; Wiley, 2000).

Additionally, translating entails more than simply changing the language; it involves translating the stories, devices, examples and metaphors to correlates that are meaningful within the culture of the language of translation. As such, developing educational technology that can be easily localized enables deeper reflection rather than

Figure 6. A three-tier file structure for multilingual multimedia (Robbins, 2004, used with permission)



surface memorization, encouraging students to think about their learning materials within their own cultural contexts while simultaneously creating culturally relevant educational media for future students.

While the approaches I have mentioned are tied to specific courseware, other methods for providing cultural context focus more broadly on cross-curricula databases of educational content from a variety of cultures. USP's multimedia database (http://mdb.usp.ac.fj) and cultural curriculum development initiative are the beginnings of multicultural learning toolsets for the South Pacific, with the promise of freely accessible educational media from various cultures of the region.

CONCLUSION

In order to help ensure that educational technology is built according to the cultures of the South Pacific rather than relying on de facto standards of the technology developers, the following suggestions are useful to consider:

- Offer opportunities for contextualization of the educational media, utilizing decentralized methods that enable "on-the-fly" staff and student input. Such approaches can be front-end, such as virtual peers from several countries who present examples and explain concepts using terms from their own backgrounds, or back-end, involving open file-structures that enable localization of supporting media files.
- Ensure that materials preserve the whole while offering specific anchors. For instance, long text should be accompanied by quick summaries that link to different parts of the main text. Graphical interfaces should present concepts through "layers of simplicity," in which details are available to the students without confusing the overall purpose of the graphics or the interface.
- Utilise modeling rather than separate instructions, enabling students to act on any instructions or practice any skills within the learning interface. For instance, overlay instructions on the active interface rather than providing separate instruction screens for help sections or lab simulations.
- Provide vernacular translations or glossaries within the educational multimedia. For ease of translation, save language files as separate text documents so that translators can make edits to the multimedia using simple word-processors, and need not know how to use multimedia development software.

This list is by no means exhaustive. Our own USP study (Robbins, 2004) explored how educa-

tional multimedia can help students with regard to computer access, reticence with authority figures, group learning, content-display and usability. Other studies have explored the role of terminology, multiple-modes and representational form (McCloughlin, 1999); icons and visual metaphors (Evers, et al., 1999); design and content-flow (Hedberg & Brown, 2002) and institutional/industrial collaboration (Kisum, 2003) in developing culturally inclusive educational technology.

The aspects of indigenous approaches to educational technology covered in this chapter were chosen because they reflect a broad scope of the educational technology development process (interface, interaction and content), and because their immediate applicability to a wide variety of educational technology can promote their further development in the educational technology community. Likewise, this chapter does not focus on differences between individual nations in the region, as such distinctions were beyond the scope and sample size of the original study, but rather on shared approaches that can be applied throughout the region.

Chapter 5.3
Using an Interactive Feedback Tool to Enhance Pronunciation in Language Learning

Felicia Zhang
University of Canberra, Australia

ABSTRACT

This chapter focuses on the effect of a learning environment in which biological, physical and technological ways of perceiving Mandarin Chinese sounds have been used. One of the most important tools of this environment is the use of a speech analysis tool for audio and visual feedback. This is done by way of incorporating a visual representation of student's production that can be easily compared to the speech of a native speaker. It is the contention of this chapter that such an interactive feedback tool in conjunction with other feedback mechanisms can provide opportunities for increasing the effectiveness of feedback in language learning.

INTRODUCTION

This chapter reports on an experiment of restructuring the learning environment using a variety of computer-enhanced language tools with the explicit aim of training students to perceive Mandarin (hereafter referred to as "MC") sounds. It focuses on the effect of creating a learning environment in which biological, physical, and technological ways of perceiving MC sound have been taught to students. It is hoped that access to these different approaches to perception will help students to know how to better perceive MC sounds outside the classroom context. One of the most important parts of this environment is the use of a speech analysis tool for offering audio and visual feedback by way of incorporating a visual representation of student's production that can be easily compared to the speech of a native speaker. It is the contention of this chapter that an interactive feedback tool such as this can provide opportunities for increasing the effectiveness of feedback in language learning. It is hoped that through the exploration of the results of this research, clearer directions on how this technology can be generalized to other learning contexts with other languages can emerge.

CRITIQUE OF VARIOUS WAYS OF TEACHING PRONUNCIATION

Practitioners of both "traditional" and "modern" approaches of language teaching have generally acknowledged good pronunciation as a very important objective in learning a second language (L2). As perception is intricately connected to speech production, training to perceive sounds necessarily becomes an important part of language acquisition and good pronunciation acquisition. However, in the history of foreign language instruction, pronunciation has not always been regarded in this light.

The grammar translation method, which focuses almost entirely upon written texts, has always considered pronunciation nearly irrelevant. The cognitive code approach also de-emphasized pronunciation in favor of grammar and vocabulary, because it was thought in the late 1960s and early 1970s that native-like pronunciation could not be taught anyway (Scovel, 1969).

Subsequent approaches, however, put more emphasis on oral communication. For example, the direct method has claimed that pronunciation is very important and presents it via teacher modeling. This methodology assumes that sounds practiced in chorus or even individually will automatically be transformed into "correct" production by the students. Similarly, the immersion method assumed that students would acquire good pronunciation through exposure. In the audiolingual approach, pronunciation is also very important. In this approach, the teacher models and the students repeat, usually with the help of minimal pair drills. However, by making students "improve" their pronunciation through a set of minimal pair drills suggests that every learner will make a particular error through a particular trajectory. For example, if an English as a foreign language (EFL) learner makes an error with the word "beach," it will inevitably be that he or she will say it as "bitch." This predetermination of what kind of errors students will make when learning a L2, not only denies a student's individuality, it also excludes many other possible causes that may lead a learner to make that particular error.

Even in the teaching approaches that focus on oral communication cited above, relatively scanty attention has been paid to the complex nature of phonation and auditory perception in a L2. In fact, teaching people to perceive in a L2 is considered so difficult that most teaching methodologies have based their approaches for teaching pronunciation on the teaching of elements that are relatively easy to define (e.g., vowel and consonant sounds). Elements that are relatively unstable and hard to define, such as intonation patterns, are usually left out of the teaching process. The teaching of intonation and rhythm has hardly been explored. The logic behind this is easily understood: one must first put together the elements of language and then, later, somehow add the intonation. These methods of teaching pronunciation have been widely used in language teaching. However, they have not yielded particularly useful results, for instance, in the field of teaching English as a second/foreign language. This led Jenkins (Jenkins, 2000) to argue that in the case of the English language, as many nations in the world use a variety of English as their own native or official language, rather than measuring native-like pronunciation or intelligibility against any particular form of the English language from say, the United Kingdom or the United States of America, it might be worthwhile to set up an international core for phonological intelligibility for the English language. It suffices to say that within this core for phonological intelligibility for English, prosodic features such as intonation were the least important according to Jenkins' reasoning. Yet this might, in fact, be approaching the problem from the wrong direction entirely.

Moreover, one cannot possibly dismiss the relationship between good pronunciation and social power. If one wants to be accepted and respected in the target language culture, the first

testament of one's worth is one's pronunciation and fluency in that particular target language. Thus, mastery of intonation patterns of that L2 is actually an integral and crucial part of language proficiency.

Finally, research by Hinofotis and Bailey (Hinofotis & Bailey, 1980) has demonstrated that "there is a threshold level of pronunciation in English such that if a given non-native speaker's pronunciation falls below this level, he or she will not be able to communicate orally no matter how good his or her control of English grammar and vocabulary might be." It is then reasonable to assume that there might also be a similar threshold level of pronunciation in MC for non-native speakers of MC. Tones in MC, as an indispensable part of intonation, perform the function of differentiating word meaning. The importance and endurance of tones in MC is such that native speakers will still find your speech intelligible, even if the vowels and consonants are unintelligible (Chao, 1972). This is why recognition bestowed upon a non-native speaker's mastery of MC is almost entirely based on native speakers' perceptions of their tones. In other words, intelligibility of non-native MC is based very much on the speaker's correct tonal production. For this reason, mastery of tone proves to be one of the most worthwhile tasks in learning spoken MC. This is true not only of a tonal language such as MC; it is also true of a nontonal language such as French (James, 1976).

In short, it is maintained that instead of focusing on the easily definable and discrete elements that make up speech, perhaps a worthwhile experiment would be to start with the intonation and the melody of a language and the process of training L2 students to perceive sounds in a L2. The study described in this chapter reports on an experiment based on this orientation of pronunciation training.

OBJECTIVES OF FEEDBACK

Getting good-quality feedback is an important aspect of language learning (and learning in general). For many educationalists, feedback is important, because it is essential for learning and can play a significant role in students' development by providing knowledge required for improvement (Hinett, 1998; Hyland, 2000). The objectives of providing feedback are as follows:

1. To enable students to understand feedback and to make sense of it;
2. To establish a common understanding of how this feedback may be implemented or acted upon by students between students and teachers.

Toohey (2000, p.154) gave a model of a learning process involving feedback: initially the student encounters or is introduced to an idea, this is followed by the student becoming aware of the idea, the student then tries the idea out, receives feedback and then reflects and adjusts the implementation of the idea. Feedback as described in this model takes place in a language teaching classroom on a daily basis. In a communicative classroom, students are frequently called upon or volunteer to try out a new sentence, conversation, or structures. The student then receives feedback from the teacher or his or her fellow classmates almost instantly in many ways. In the classroom, many channels are used for communicating feedback, through error correction and other channels, such as body language, nonverbal behavior, facial expressions, gestures, tone of voice, and so on. Such feedback is usually instantaneous, involuntary (from the feedback provider), episodic, and disappears very quickly from the memory of everyone involved. So in a traditional classroom, while we receive a huge amount of feedback on our production, the feedback received seldom becomes guidance or long-term learning in a real,

face-to-face communicative interaction outside the classroom.

First, can we expect the classroom situation to provide feedback that is able to achieve the objectives listed above? Clearly, the episodic nature of the feedback offered in the classroom can have minimal effect on student learning. Second, understanding what the feedback contains and how to act on it are not as easy as they seem. The feedback offered in a L2 language classroom does not only contain information on the correct way of pronouncing or writing something. In some cases, error correction offered can be as detrimental as not offering any feedback at all. An excellent example is in the teaching of MC tones. In a character-based language such as MC, each character has a lexical tone that is stable when it is isolated from other words. However, in a sentence situation, a lexical tone of a character is influenced by other characters and their tones before and after it. In other words, a character might lose its stable lexical tone in a larger stretch of discourse. In the MC language, changes in tones across sentences and longer stretches of discourse are very hard to predict and describe. Yet, in every classroom in the world where students are learning MC as a foreign language, teachers are constantly pulling students up on their tones by demonstrating the right tones for individual characters and telling them the tone for a particular character is a fourth tone not a first tone and so on. The problem is that such corrective effort is usually ineffective, as the immediate context (influence of words left and right to the character in question) of the correction for that particular character is ignored, and the effect is usually short-lived and transitory.

THE CONTRIBUTION OF COMPUTER TECHNOLOGY IN FEEDBACK PROVISION

The advent of computer technology in language learning has added a very interesting dimension to the role of providing feedback. Computer technology can provide an environment in which certain memory traces that work for a particular learner can stay longer in that students' consciousness or sometimes unconsciousness. In a real-life situation, such memory traces can be called upon to help facilitate the communication involved. The advantages of feedback offered by a computer are that the feedback is constant; it can be repeated over and over; and it allows students to control their own learning.

However, the design of CALL tools for providing feedback still depends on the theoretical framework that conceptualizes the tools. For instance, in a Speech-Recognition-Based pronunciation training experiment conducted by Tomokiyo et al. (2000), the feedback offered still follows the model of offering explanation using diagrams of articulatory position and minimal pair practice. Many CALL tools still tend to focus on the production side of pronunciation rather than on exploring how students perceive sounds. Thus, the criticisms that are put forward against the various approaches of teaching pronunciation in language teaching are equally pertinent here as well. The present study proposes that instead of conducting research based on the more stable aspects of pronunciation (i.e., vowels and consonants) that are constrained by particular theories of linguistics, it might be more productive for students if we conduct research based on sound theories of learning. The speech tool we developed, and which will be discussed in more detail shortly, is based on verbo-tonal system of phonetic correction, developed by the late Professor Guberina in connection with his work with people whose hearing was impaired (Renard, 1975). This is a system that brings the human brain and the human body as a whole to the forefront of the study of auditory perception. The computer software is used in a language learning environment that has been designed to use all the sensory organs of the body to facilitate auditory, visual, and other perceptions and to contribute to the brain's realization of every perception.

Most of the feedback that is currently offered in computerized multimedia environments is focused on the product of student's performance rather than upon the process. For instance, we are familiar with many language-teaching exercise makers that allow you to offer feedback such as "try again" or "well done." However, such feedback is pointless, and students are unlikely to benefit from it if they do not change their actions during the process of production. In the case of getting better pronunciation in any language, this amounts to getting students to try to say a sentence differently. Most feedback mechanisms, while offering feedback in terms of judgment, do not offer any feedback that contributes to the process of production. The speech tool we developed, by contrast, is designed to offer feedback that is nonjudgmental and allows students to explore and reflect during the process of learning, not just at the end of the learning process. Reflection occurs when students can observe visually the differences between their productions and the native speaker model. When this is combined with the biological and physical memory traces built up in the classroom context, students can act upon their reflections and change the processes of production. It is the contention that this way, students will be able to turn feedback to students into learning in the long run.

Providing Feedback Using Sptool

A few attempts have been made to teach melody and intonation in a new and original way by displaying the melodic contours on a screen. The students hear a model sentence and, at the same time, they watch the melodic pattern form on the screen where it is "frozen." They then attempt to match the model melody by speaking. As their melodic pattern is also "frozen," they can compare their productions with the model. Students can then employ auditory and visual stimuli for assistance in the comparison process. Such methods, overall, have had good results (James, 1976). In the past, this kind of feedback machine was relatively expensive and, as only one person could be trained on any single machine at any one time, not really feasible for widespread educational use. However, computer technology has made it possible that such a feedback mechanism can be provided at the click of a button. The Sptool (Zhang & Newman, 2003) used in this research is such a feedback mechanism.

The Sptool program is produced with a windows component called dotnetfx.exe; it is 20 megabytes in size. It is most stable for Windows 2000 and XP; a bit unstable for Windows 98. When you open the program, you can see the open icon, which allows you to import any other prerecorded audio file saved in the .chwav, .mchwav, or .wav formats. If you have a prerecorded sound file, saved in Windows .wav format, you should be able to open it and run through the program. If you record a male voice in Cooledit (Syntrillium, 2002) or any other recording software, save it under the Windows .wav format to .mchwav. If you record a female voice, save it to .chwav, and then Sptool should play and measure your recorded sentence. At the moment, the program is not able to work with large files over 10 megabytes due to the limitation imposed by the Microsoft component.

Other Speech Analysis Tools

There are other speech analysis tools on the market. The commercial product Winpitch (Martin, 2003) is such a speech analysis tool. Praat (Boersma & Weenink, 2003) is free and also available. However, these software programs are far too complex for beginning language students to use. As the students involved in this research are zero-level beginners of MC with varying computer literacy levels, the complexity of the programs described above made the creation of a more user-friendly speech analysis tool integrated into the teaching material a necessity.

The Tell-Me-More series (Auralog, 2000) of language-learning programs also have built within them a speech comparison tool. However, the speech comparison chosen by the creator of Tell-Me-More is using phoneme matching. In other words, while the sentences contained in the language program can be verified by the speech comparison tool attached to the program, it cannot verify any other sentences outside the program. This means the usefulness of their speech tool is really limited.

THEORETICAL FRAMEWORK UNDERPINNING THE CURRENT RESEARCH

The use of Sptool is embedded in a larger learning theory based on the theory of the verbo-tonal system of phonetic correction. This theory is mainly concerned with the way students perceive sounds of a L2. The starting point of this theory is the complex nature of phonation and auditory perception of a language. From the verbo-tonal point of view, auditory perception develops synchronously and synergistically with the development of the motor, proprioceptive, and visual abilities (Guberina, 1985). One of the senses in audition is through the ears. A person with normal hearing in his mother tongue will behave, in a foreign language, as though he or she were hard of hearing. Each language sound carries all frequencies from about 50 Hz to about 16,000 Hz (albeit at various intensities). Theoretically, at any rate, each sound can be heard in many different ways. The ear seems to have a "choice" as to what to hear, in practice, depending on the way in which the ear has been trained. L2 students tend to make "choices" in the target language based on what they are familiar with in their mother tongue. Each sound has a particular "optimal" frequency (i.e., the frequency band, or combination of frequency bands, at which a native speaker best recognizes and perceives the sound in question). This is what Troubetzkoy (1969) referred to as the mother tongue "sieve."

Students who experience difficulty with a particular foreign language sound are considered as not having recognized its optimal. Hence, they are unable to reproduce the sound correctly. One of the ways in which students can be made to perceive the optimal of each sound is to remove (e.g., through electronic filtering) any interfering frequencies that might prevent it from being perceived. In this way, it is possible, in theory, to bypass the mother tongue "sieve" (Troubetzkoy, 1969). Once this has been achieved, students will be able to perceive, for the first time, the specific quality of the troublesome sound. However, exposing the students to the native speaker optimal may still be insufficient. A set of "corrective" optimals then needs to be determined. These will be such as to direct a student's audition away from its natural tendency to structure as it has always done.

Verbo-tonalism postulates that the articulation of sounds poses relatively little difficulty once the specific quality of the sound has been heard. Consequently, the determination of corrective optimals for any one student will be established on the basis of his or her pronunciation. It is through exposure to corrective optimals, followed by intensive articulatory practice, that students will carry with them valid acoustic models constituting the normal range for the phonemes of language. The intense exposures to the sentences in this course via the Sptool plus the intensive articulatory practice carried out in the two-hour lecture provide students with such valid acoustic models of the phonemes of the L2.

Audition is a form of total behavior that occurs on the level of the body as a whole. In the present course, nine steps in the lecture sequence have been designed to integrate phonation and expressiveness that occur in the space between the lungs and the nasal cavity, with the breathing, moving, feeling patterns of a person in entirety so that a multitude of memory traces will be retained in different parts of the body.

Given the complexity of the various processes involved in perception and phonation, an intellectualization of these processes is unlikely to be successful. Learning processes must therefore operate at the "unconscious" level. Rather, it is essential that proprioceptive powers be called into play in the development of good pronunciation so that students might become conscious and perceptive of the rhythms and stresses of the target language. The fact that translation into English, romanization in Pinyin, etc. are not emphasized or used at all in this course suggests that the course is especially designed to allow new language to be processed "unconsciously"—or perhaps *intuitively* would be a better word—first and foremost. In other words, we are not really talking about unconscious learning but the more intensive utilization of the language centers through the exploitation of different parts of the nervous system, such as the parts that are concerned with proprioception and bodily sensation.

The elements described in the following lecture sequence and the audiovisual materials contained in the teaching materials represent the pedagogic measures that integrate the senses of the body with movement with the process of ear training through working on a system of errors rather than isolated elements of the language. It is proposed that starting an audition process from intonation would result in the proper training of several systems at once in MC. These pedagogic measures also are designed to instill in students certain memory traces by physically "marking" on their brains so that these memory traces can be reactivated once feedback either from Sptool or from any other sources has been received.

These memory traces are essential in enabling students to act upon the feedback received. This is the second important objective of any feedback system: to create a set of memories that are not merely cognitive records but feelings of relaxation and muscular tension that are distributed through the students' experience of his or her bodily sense. What follows is a brief description of a teaching method that, in helping to create such somatic traces, provides an environment suitable to the inclusion of the Sptool and assists students in the exploitation of that resource.

A NEW METHOD OF TEACHING MANDARIN CHINESE PRONUNCIATION TO BEGINNERS

It is 5:30 pm on a Tuesday afternoon, in a large room capable of holding up to 50 students; the lecture chairs with attached arms have been pushed to the perimeter of the room. The students are randomly slouched on their chairs relaxing after a tired day of either work or lectures.

The teacher walks into the room carrying the necessary computer gear, CD-ROMs and so on. She greets the class cheerfully with "ni3men hao3" (hello, everyone) and puts the CD-ROM in the computer. "Now, leave your seat and lie comfortably on the floor and listen." Then the following audio file is played:

"Imagine that you are lying on your back on the grass on a warm summer day and that you are watching the clear blue sky without a single cloud in it (pause). You are lying very comfortably, you are very relaxed and happy (pause). You are simply enjoying the experience of watching the clear, beautiful blue sky (pause). As you are lying there, completely relaxed, enjoying yourself (pause), far off on the horizon you notice a tiny white cloud (pause). You are fascinated by the simple beauty of the small white cloud against the clear blue sky (pause). The little white cloud starts to move slowly toward you (pause). You are laying there, completely relaxed, very much at peace with yourself, watching the little white cloud drift slowly toward you (pause). The little white cloud drifts slowly toward you (pause). You are enjoying the beauty of the clear blue sky and the little white cloud (pause). Finally the little white cloud comes to a stop overhead (pause). Completely relaxed,

you are enjoying this beautiful scene (pause). You are very relaxed, very much at peace with yourself, and simply enjoying the beauty of the little white cloud in the blue sky (pause). Now become the little white cloud. Project yourself into it (pause). You are the little white cloud, completely diffused, puffy, relaxed, very much at peace with yourself (pause). Now you are completely relaxed, your mind is completely calm (pause), you are pleasantly relaxed, ready to proceed with the lesson (pause)." ***(Step 1)***

"Now, get up and stand in a circle." The teacher joins the circle.

The teacher says "I will hum to the rhythm of the sentence and please hum with me while walking slowly in a circle." This is done five times. ***(Step 2)***

"Now, I will clap to the rhythm of the sentence and then you can clap after me." ***(Step 3)*** *Again, this is done five times.*

"Notice the high sounds and the low sounds in the sentence? With your palm up, push your hands above your head as high as possible for the high sounds. For the low sounds, stamp your feet done as hard as possible. Now let's hum the sentences again." ***(Step 4)*** *This is again done five times.*

"Continuing with the movements, now mouth the sentences while I say them out loud." ***(Step 5)*** *Of course, at every lesson, at this stage, one or two people always end up repeating the sentences rather than mouthing them. This is again done five times.*

"Now repeat after me, and then add words to the intonation." This again is done five times. ***(Step 6)***

Now the teacher instructs each individual to repeat the sentence by themselves; checking that each student is reproducing the sentence correctly. ***(Step 7)***

"Now what is the meaning of the sentence?" Students enthusiastically volunteer the meaning in English, and the meaning of the sentence is usually established in seconds. ***(Step 8)***

In each two-hour lecture sequence, every sentence is presented and practiced using the above procedure. At the end of each lecture, the whole class engages in a pair or group work conversation activity using the materials covered in the lesson. ***(Step 9)***

At the end of the lesson, students are instructed to sit and write the meaning or whatever notes they want to make themselves.

In the lecture sequence described, several rather unconventional elements make an appearance. For instance, relaxation exercise, humming, mouthing to the words, body gestures, and mouthing the words and then repetition, are all present in the learning sequence. How are these related to each other? How do these elements relate to the Sptool under discussion?

Focusing on the Rhythm and Intonation of the Language

The activities described in the above lecture sequence all have to do with focusing on the rhythm and intonation of the language. Intonation is a universal feature of all languages. Melody (which includes tones and intonation) holds the units together and arranges them with respect to one another. It is a very special kind of glue. Attempting to arrange the sounds with the wrong "glue" is like building structures of the wrong kind.

The smallest unit of the language being presented is a sentence rather than individual words or compounds. This is because in MC, the acoustic characteristics of the words change when they are in a sentential environment. For instance, when a word is read in isolation, the frequency of the word is different from when the word is part of a sentence. So concentrating one's effort in mastering the tones of individual words or compounds does not guarantee success in producing the sentences containing those words. This is true of MC as well as other nontonal languages.

Step 1: In this step, the imagery of the "little white cloud" is used to relax the students and the teacher. This constitutes the *relaxation* phase. This sets up a relaxed atmosphere for learning for the rest of the lesson. Stevick (1986) has stressed the usefulness of working with imagery in language teaching. In education, visualization can facilitate the interiorization of knowledge by creating a more receptive state of awareness, permitting the affective and creative functions of a more holistic nature to participate in and strengthen the learning experience (Murdock, 1987). According to Neville (Neville, 1989), "the fragmented, dispersed, chaotic energies of our organism are aligned, harmonized and made purposive by the imagined experience, just as they would be by a 'real one', possibly leading to important changes in our 'self-image, attitude and behavior' (p. 95).

Step 2: This step involves humming along to the rhythm of the sentences without the vowels and consonants (five times). This is used to highlight the intonation and tones of MC.

Step 3: Clapping to the rhythm allows students to experience the rhythm of the sentence and observe different groupings of the words in a sentence. This also allows the students to observe how stress, realized by length and loudness in MC, is tied to meaning. This also allows them to observe the key words in a sentence and realize that not all words are of equal value and that in making oneself understood, one only needs to get the key words right. This training is essential in training them the strategy of prediction and advanced planning in listening comprehension.

Step 4: In this step, walking about with feet coming down on every syllable is practiced in order to get the body used to producing a tense downward tone that is also loud. Raising or stretching upwards as though attempting to touch the ceiling to experience the tenseness of the body in producing the first high level tone is also done. Instruct the students to adopt a forward lumping of the shoulders for the second and third tones in MC that need a relaxed posture.

Research shows that Chinese speakers have a much wider voice range when speaking MC than English speakers speaking English (Chen, 1974). As the first tone starts at a higher frequency than what most Australian speakers are used to, extra physical efforts need to be made to remind one that one must start high. To stretch one's muscular system to express these MC tones, one must not slouch in seats. By asking students to stand up straight and walk in a circle with various gestures, students are experiencing the coordination and synchronization of various muscles with the sounds uttered.

Steps 5 through 9 are steps that further highlight the melody of the sentences involved. Notice that throughout the learning sequence, translation and writing down the sentences are not needed until the last moment. By the time students come to write down the meaning, they will have already internalized the melody of the sentences.

The nine steps of the lecture sequence offer students a range of physical ways for remembering tones beyond the set contact hours every week. These measures set up a series of learning steps that can be used for self-access learning at home.

ROLE OF THE SPEECH TOOL AND THE COURSE DATA CD AND AUDIO CD

Course Data CD

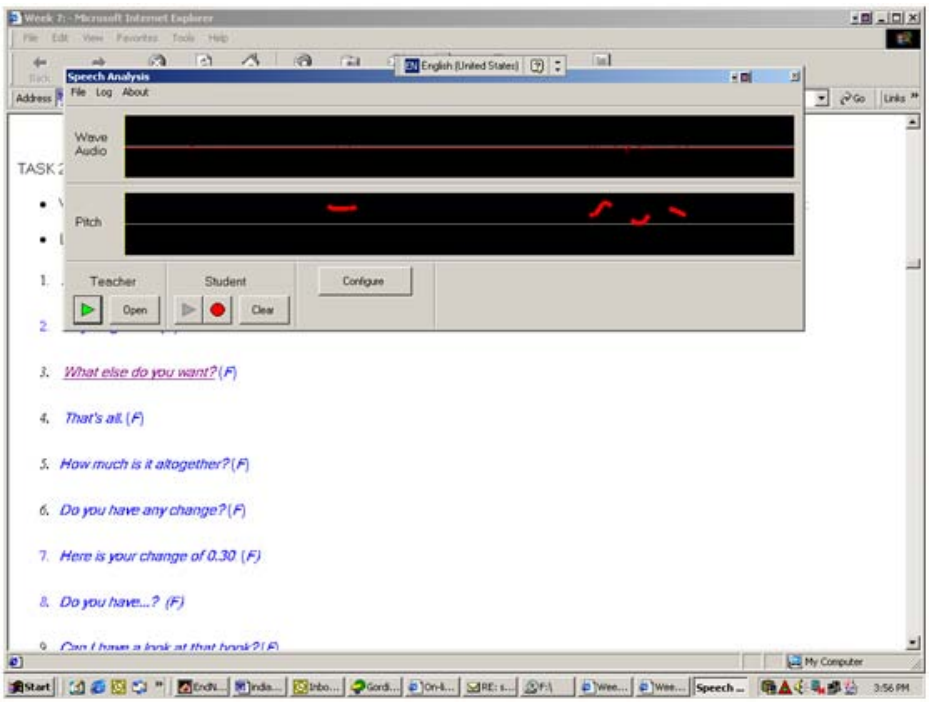
Each new vocabulary item, new sentence, or new phrase in the teaching materials is linked to a normal sound file. Only the sentences are linked to both a normal sound file and a filtered sound file.

All the sound files in the materials can be passed through the Sptool (Figure 1). Once passed through the Sptool, the learner can listen to the teacher's model pronunciation by clicking on the "teacher" icon. With one click, the student can hear the model sentence, and the pitch curves of the model sentence are displayed. If the learner wants to hear a smaller chunk of the sentence, then he or she can select that bit of the curve by dragging the cursor over the portion they want to hear. After listening to the sentence numerous times, the learner can decide whether he or she wants to record his or her own production.

Before clicking on the record button, however, it is necessary for the student to tell the program whether he or she is female or male. This is necessary because females generally have higher fundamental frequencies than males. The difference is sometimes as much as over 100 Hz. If the program is configured to measure a female voice, the pitch curve of a male learner will not be able to be displayed. However, once configured correctly, the pitch curve of the learner's recording will then be displayed properly.

The course data CD also contains teaching materials in html format; all the associated sound files, the Speech tool, and short video skits with which students can test their comprehensions of the new language can be learned by watching these video skits. An audio CD of the sound files is also provided with the course materials. In 2003,

Figure 1. Picture of the teaching material



a weekly compulsory class using computer-enhanced teaching materials was arranged. Other computer-enhanced learning materials such as Tell-Me-More (Auralog, 2000), VCDs, movies, and videos with similar content are also available in the computer center.

The Role of Sptool

Steps 2 to 7 in the lecture sequence are duplicated in different forms through the use of the Sptool. While the classroom sequence is more or less teacher driven and physical, the Sptool allows the lecture sequence to be experienced in a different way. It also allows other choices to be made:

- The beat, stress, word groupings, key words, and sentential intonation are all indicated in the speech curve and the sound file. In the sample sentence, zai4 nar3 you3 mai4 bi3 de0 (Where can one buy some pens?) shown in Figure 2 on the next page, "zai4 nar3" is the key word and the curve clearly shows that the three characters are in a group together and should not be separated.
- The height (related to the muscular tenseness of the body) of both first and fourth tones is indicated clearly with respect to other tones. The height of the first and fourth tones reminds the students of the need to stretch their voice range beyond their normal voice range. This information is very useful in enabling students to change their ways of producing the target sentences after observing the differences between the native speaker's production and theirs.
- Comparison of the pitch curves of individual words in the vocabulary section with the same words used in sentences is possible.
- Students can select any portion of the sentence for listening practice and repetition.
- The links between words are easily observable. For instance, in the sentence,
  Wo3 sheng1yu2 yi1 jiu3 wu3 ling2 nian2.
  I was born in the year 1950.

The production of "sheng1yu2" requires the body to be tense and to be kept tense in order to produce the next "yi1: one." Students can select the three syllables "sheng1yu2yi1" in order to explore how physically one has to keep one's body tense in order to produce this group of words using the physical gestures practiced in the classroom.

The use of Sptool encourages students to reflect on and explore the process of learning. Many of the explorations are usually impossible to be predetermined by a teacher, as most teachers, even the most able, do not have an extensive list of rules about how the different combination of words are produced physically in MC. Many of the things that can be done using the program may not be initiated by teachers but are being explored by the students through use. Furthermore, being able to experience each sentence repeatedly through the Sptool creates an environment in which students can totally immerse themselves consciously and unconsciously in the language.

THE STUDY

Sample

The progress of three groups of beginners of Mandarin Chinese has been followed. The first group (hereafter referred to as "Group 1") consists of two other groups of total beginners from 1995 and 1996 who were taught pinyin (the Chinese romanization) from the beginning of their MC study. The oral test data collected from this group represent the baseline data.

The second group (hereafter referred to as "Group 2") of beginners finished their two semesters of study in Mandarin in 2001. These participants were students enrolled in *Chinese 1a: Language and Culture* and *Chinese 1b* of the first-year Chinese course at the University of Canberra in 2001. By the end of the experiment, they had completed 130 contact hours of lectures and tutorials over two semesters.

The third group (hereafter referred to as "Group 3") consisted of students who studied MC in the first semester, 2003. Students in Group 3 were zero-level beginners when they started and were taught exclusively by the use of the Sptool. These participants in this study were 15 students enrolled in *Chinese 1a: Language and Culture* in 2003. There were three students from Japan, one student from Korea, and 10 Australian students. By the end of the experiment, they would have completed 65 contact hours of lectures and tutorials over one semester. They were all zero-level beginners of MC at the beginning of the course.

Data Collection Methods

A configuration of data methods was used to explore the experiences of Groups 2 and 3 students as they learned MC through this technology-rich learning environment. The configuration of methods is as follows:

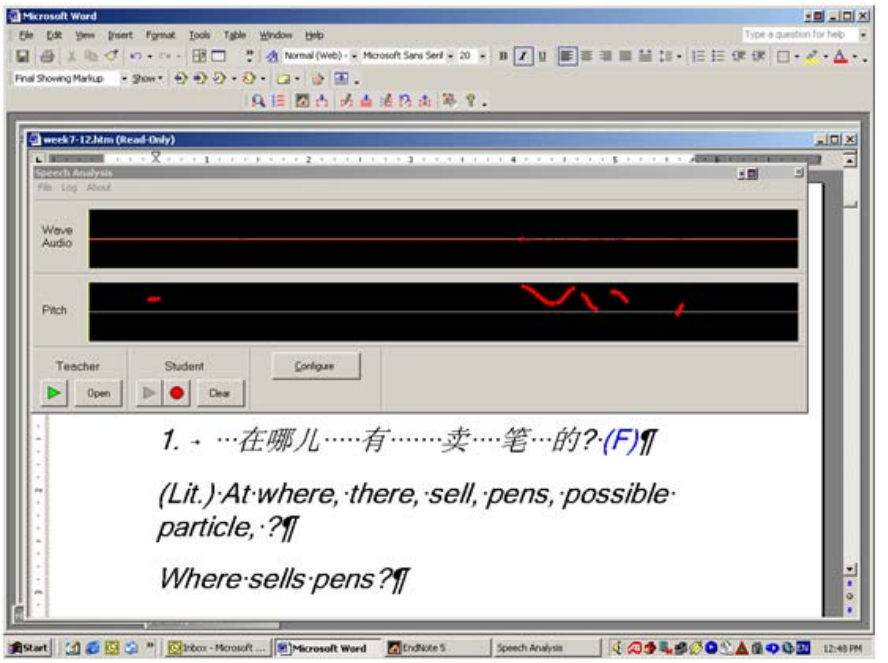
Qualitative:

- One-to-one oral tests (four of them for Group 2; one for Group 3)
- Self-scripted video segment done in small groups (four for Groups 1 and 2; one for Group 3)
- Written examination tests (four for Group 2; and one for Group 3)

Quantitative:

- Computer-technology-related questionnaires from Group 2 students
- One-to-one interviews with Group 2 students

Figure 2: Picture of the Sptool showing the sample sentence: Where does it sell pens?



RESULTS AND DISCUSSION

Qualitative Data

Group 2:

Data collected from the 2001 group of students were compared with two other groups of total beginners from 1995 and 1996. The fundamental difference between the groups was that the 2001 group of students was not taught pinyin from the very beginning. Analysis of students' oral performances revealed that the rate of acquisition of MC initials (consonants) and finals (vowels) was faster for these students. For instance, in the data from students in Group 1 (the pinyin group), a large number of errors with palatals [x] and [j] and [q] were present. While the Group 2 students made some errors with [x] and [q], errors with [j], after only six weeks of instruction, did not occur. Furthermore, by the time the second oral (after 65 hours of instruction) was conducted, no errors were made with respect to these initials.

Group 3:

Students in Group 3 started learning Mandarin only since the end of February 2003. This group is the only group that benefited with a verbo-tonal-theory-driven teaching methodology combined with a fully developed software package that included course data and audio CDs and the speech tool. By the end of May 2003, this group of students had completed their first written and oral tests.

Oral test:

The first oral performances of eight students in Group 3 had been analyzed. Out of 1827 words (MC characters) uttered, 77 errors were made with consonants and vowels. In other words, only 4.2% of errors were made. Out of the 77 errors, students from a non-Australian background, i.e., one Korean, one Thai, and one Cantonese speaker of Chinese made the majority of the errors. In terms of consonants, only one Australian student made two errors with "zhi3." He pronounced it as "zi3." Again, errors with palatals [x] and [j] and [q] were not present. After only 30 hours of face-to-face instruction, all the Australian students had gained complete control of the initials of MC. Similar to previous groups of students, pinyin and non-pinyin groups, the problematic errors were with the vowels and diphthongs rather than with consonants.

The faster rate of Mandarin sound system acquisition can be attributed to the removal of romanization and the availability of sound files on CDs and the speech tool. The combined effect of both tools appeared to have helped to reduce the transfer effect from the students' mother tongue—English. A close examination of the audio recordings of Group 3 students' oral also suggests that Group 3 students were more fluent. Though they still had tone problems, the rhythm of their speech was much more natural when compared with a native speaker's rhythm.

Furthermore, anecdotal reports from students suggested that students were confident with their listening comprehension ability, citing that the use of humming, clapping, and so on in class combined with the use of Sptool, allowed them to hear and remember more distinctly the rhythm and stress of the language. This meant that they were able to hear familiar key words that enabled them to predicate what was coming up more accurately. Evidence of this came in the form of the ranking of students in different parts of their written tests. For this group, the top three ranks were occupied by Australian zero-level beginners overall. For the entire group, for the listening comprehension section, even the weakest student (the student who scored the lowest for the entire written test) scored well for this section. This was very different from the results of previous years. As one student remarked, this course was more like an immersion language program in which

students were expected to use the whole body in the process of learning.

Quantitative Data

Group 2: Results of the Computer Technology Questionnaires:

The reaction to the computer-based materials was extremely positive with this group of students. Many, 85%, of the students regularly used the audio and data CDs for at least one to three hours per week in an evaluation survey conducted at the end of the first semester in 2001. At the end of the first semester, students requested that in the written text on the data CD, each line of each dialogue be linked to its corresponding sound file, thus making the practice of the target language, line by line, easier.

A similar technology-oriented questionnaire was also administered at the end of the second semester. All students used the course data and audio CDs regularly to prepare and review the materials covered. Two out of six students requested each item of the vocabulary each week to be linked to its own audio file. Two students requested more regular use of VCD, and some requested more regular use of the Tell-Me-More CD in class.

Group 3:

No quantitative data had been collected from this group of students at the time of writing this chapter. Both questionnaire and interview data have been collected in late June of 2003 but are yet to be analyzed. A brief glimpse of the questionnaires completed by Group 3 students suggests that, on average, these students spent around 10 hours per person outside class contact time on their Chinese learning. This kind of devotion to the learning of MC has not been experienced by the researcher in her entire teaching career.

The availability of such an array of computer-enhanced learning materials encouraged students to engage in more autonomous learning behavior. As pronunciation could only be obtained either through looking in the dictionary or listening to the accompanying course CDs, all students spent time on a regular basis to listen to the CDs to prepare for the week's materials. This autonomous learning pattern actually forced students to open their ears to the target language in and outside of class, thus enormously increasing exposure to the target language. Autonomous behaviors happen every time each student listens to a string of sounds in Mandarin, as each student has to perceive the sounds according to his or her individual perception and translate them in a way that is recognizable to each student, individually.

FUTURE DIRECTIONS

It is important to note that Sptool can be used with any language, whether mother tongue, L2, or languages in danger of becoming extinct. It can be used with languages or any sound wave. Therefore, it can be used to enhance the teaching of the prosodic aspect of any language. For instance, in the teaching of English, the Sptool described in this chapter makes it possible for different models of native English sentences to be made available to teachers and students.

The Sptool used in the learning process is by no means perfect and, therefore, can be further improved in several aspects:

1. At the moment, it can only work with pre-produced sound files of a fairly small size. This means that a sound file has to be prerecorded before it can be run through this tool. It will be a huge improvement if as soon as someone speaks, the speech is recorded and automatically analyzed with the pitch wave displayed on the screen instantly. In other words, this tool should be able to process speech in real time.

2. Another icon called "filtered" can be built into the program to display the filtered version of any sentences.
3. This program should be able to talk to other programs, such as a video database, so that the sound file from any movie can also be measured and displayed instantly.
4. Band passes can be built into the program so that students can investigate the "optimal" frequency of a particular consonant or vowel.
5. A Web-version of the course should be created, and flash technology should be used so that once students point on a sound file, the speech tool opens automatically.

While Improvements 1 through 3 will not make the program too complicated to use, a large amount of research needs to go into investigating the possibility of Improvement 4. Improvement 5 is also possible, but the use of the World Wide Web itself already restricts its use. However, a Web version of the Sptool is being planned.

One of the most promising research directions at the moment with regards to this program is further improvement of the program and then testing of the tool with a larger group of students in different languages.

CONCLUSION

Limited findings described in this article demonstrated that a well-thought-out and properly implemented curriculum involving computer technology can make feedback to students more effective. This kind of environment is instrumental to produce students with better pronunciation in a L2 and can increase students' motivation for learning the language and culture of an L2. One significant consideration of creating this environment is the fact that the technology chosen is of a "*low-tech*" nature, utilizing mainly CD-ROM technology. While it has been acknowledged that adding the Net to this learning process may also be beneficial for students, at the beginning stage of language learning, the use of the Net only serves to increase the cognitive load on students.

Another significant characteristic of this environment is its *modularity*. I would like to refer to all the elements within the environment metaphorically as "machines." The "machines" used in the environment are easily accessible and user friendly and adaptable. The non-technology-driven elements such as one's body, voice, movement, and gesture are already available to every student. The technological elements, such as the sound, video, text files, and filtered sound files, are not hard to produce. The frequency of interaction and ease of access afforded by the Sptool and other sound files have been extremely motivating for students. Through the use of various machines in this environment, feedback, offered through physical, biological, and technological means, has acted in concert to motivate students and convert feedback in learning.

ACKNOWLEDGMENT

The investigation described in this chapter is sponsored by a University of Canberra research grant, 2002–2003 from the University of Canberra, Australia. I would like to thank Professor Michael Wagner for participating in the grant and offering me useful feedback and advice throughout the grant.

I would also like to thank Kate Wilson and two anonymous reviewers for helpful feedback on a previous version of this chapter. I am, however, entirely responsible for the good and bad herein.

Chapter 5.4
Web-Based Synchronized Multimedia Lecturing

Kuo-Yu Liu

Herng-Yow Chen
National Chi-Nan University, Taiwan, R.O.C.

INTRODUCTION

Over the last decade, the emerging Web technologies have opened a new era for distance education, where online courses can be created and accessed in a very easy way not previously available. Many online courses based on HTML pages thus are now available in cyberspace for synchronous or asynchronous distance learning (Anderson, Beavers, VanDeGrift, & Videon, 2003; Gregory, 1999; Muller & Ottmann, 2000; Shi et al., 2003; Siddiqui & Zubairi, 2000). However, without the support of multimedia, the static HTML pages can only serve as different kinds of simple "dumb" lecture notes on a network. Thus most students may lose interest quickly and eventually give up self-learning (Zimmer, 2003). Furthermore, this kind of unguided, static HTML pages are clearly insufficient for diverse learning needs and for different knowledge domains. With the dramatic development of multimedia technologies, we can integrate various media and provide students with vivid multimedia lectures on the Web. For example, the presentation techniques of online language courses should stress the importance of multimedia (e.g., voice and video) and document interaction flexibility (e.g., random access and repeated play of a specific speech segment) much more than other courses do (Brett, 1998; McLoughlin, Hutchinson, & Koplin, 2002).

The Computer-Assisted Language Learning (CALL) has existed for a long time and has used the computer technology with advanced multimedia and Web technologies to fulfill a certain pedagogical approach (e.g., listening, speaking, reading, and writing) since 1990s (Warschauer, 1996). The purpose of this study is to explore in what ways multimedia and Web technologies can help, and how they can do so in our developed system—the Web-based Synchronized Multimedia Lecture system (WSML)—to make online foreign language teaching and learning more effective

(Chen, Chen, & Hong, 1999). The WSML system has been applied to online language learning that includes English as Second Language (ESL) learning for Chinese students (http://english.csie.ncnu.edu.tw) and enhancement of Chinese for overseas Chinese students (http://chinese.csie.ncnu.edu.tw) in National Chi-Nan University.

The advantages of the WSML system are described as follows:

- **Providing different types of materials can enhance students' capabilities in English/Chinese:** The online teaching materials come from two types of language-learning activities (or sources) with which most students are familiar: (1) lectures with teachers' guidance—the recitation or explanation of an article created and/or used in a real classroom process/experience; and (2) self-learning content without teacher's guidance—the Web/Internet resources beneficial to students' learning. The material involved in a real-classroom activity may include instructors' speech (and/or video), HTML-based lectures, and lecturing events imposed on the HTML lectures. The Web/Internet language material can be HTML-based headline news transcripts and the corresponding news speeches.
- **Providing easy-to-use authoring tools can assist teachers to generate multimedia lectures:** In contrast to the static HTML-based documents, authoring a multimedia document requires much time and work. Therefore, the WSML system provides several authoring tools to assist teachers to create teaching materials, record oral guidance, and capture navigation events without programming skills (Lower, 2001).
- **Web-based multimedia tutoring breaks the limitations of conventional teaching environments:** The online courses provide flexibility for those who are limited by time, distance, or physical ability. Students can choose a suitable course according to their learning situations or suggestions from the teacher. Hence, with the WSML system, students can get adequate practice in listening, reading, and writing.

BACKGROUND

Let's take an English as a Second Language (ESL) course at our university as an example. Instructors usually prepare the teaching materials (e.g., HTML-based reading essays) accessible on the Web for student pre-readings. In class, the instructors use a computer, a microphone, and an LED projector to assist teaching. After opening remarks, the instructors may recite the article to students once at a slower pace before going through other details, such as vocabulary definition and explanation, and so forth. After class, the students are requested to write a reflection on the topic having been taught and to submit the homework through an e-mail or a Web-based submitting interface. Then, instructors receive students' homework, print it out, correct directly on it, and return it back to the students in a later class. This is a model with which we are most familiar and have used for a long while. The computer and network/Web technologies used here are merely to facilitate content exchange between teachers and students.

Imagine that if students could, for example, listen to (and see animated) an online lecture or their own homework as corrected by their teachers, and if a particular text units of the lecture (e.g., keywords and sentences) could dynamically be highlighted in synchronization with the playback of the corresponding speech; students could learn the points more effectively and efficiently. Therefore, the goal of the WSML system is to fulfill the scenarios described above. In what follows, several related works on language learning will be discussed, and the multimedia synchronization issues providing an integrated

synchronized presentation of the WSML system will be investigated.

RELATED WORK

Several language-learning systems have been developed by integrating state-of-the-art multimedia and Web technologies for online language learning. The purpose of these systems is to develop functionalities that support language learning in listening, speaking, reading, and writing skills or online assessment.

Web-CALL (Fujii, Iwata, Hattori, Iijima, & Mizuno, 2000) is an easy-to-use system allowing teachers to add or modify the content of the teaching materials according to their needs. The construction of Web-CALL consists of two units: a Web-page Materials Production Unit (WMPU) and a Learning Support Unit (LSU). The former is a useful tool for teachers to produce Web-page materials without knowledge of programming skills, and the latter enables students to study online language lessons produced by the teacher. Multimedia features such as sound, pictures, and movie files can be attached to a lecture as supplemental materials.

The goal of the Intelligent Web-based Interactive Language Learning (IWiLL) (Kuo et al., 2001) system is to build a networked learning system by integrating language pedagogy, linguistics, computer networks, and multimedia technologies. Two kinds of writing environments in IWiLL are designed to support asynchronous and synchronous writing correction process. The asynchronous writing environment mainly provides functions allowing students to submit essays via the Internet and to examine essays that have been corrected by the teacher. The synchronous writing environment provides functions enabling students and teachers to work on the same essay and to communicate with each other in real-time. In addition, Video-on-Demand technology is also applied in the IWiLL system to support online movie access.

The BRIX system (Sawatpanit, Suthers, & Fleming, 2004) was developed to address the need for a generic language-learning environment that fulfills language-learning activities. Ease of use was important in the design of BRIX, which can yield great benefits to teachers by saving the time and cost of developing courseware. Several functions are implemented for teachers to create teaching materials, such as vocabulary, grammar, discussion, essay, self-test, and quiz. All of the resources can be accessed by the students via the Internet.

The systems described above primarily use the network to distribute and share the language-learning resources. However, multimedia features that are most important for developing online learning systems, particularly for language learning, are less investigated. Web-CALL loosely integrates multimedia files by containing voice information in lectures for listening practice. For the IWiLL system, co-editing and online conversation capabilities are beneficial for essay correction. On the other hand, online movies are other types of teaching materials for listening practice. In contrast to the Web-CALL and IWiLL systems, the BRIX system paid little attention to the use of multimedia materials. It focused on development of functions for fulfilling the instructional activities.

In this article, we present a language-learning system based on developed WSML technology to construct a vivid and vigorous Web-based instruction environment. In the WSML system, teaching materials containing various types of media such as audio-video and navigation events (e.g., pen strokes, highlight, dynamic annotation, tele-pointer, scrolling, etc.) are fully integrated to benefit students in language-learning skills. The elaborate online exercise design is also helpful for self-learning of students. Table 1 shows the summarized assessments of the four language-

Table 1. Summarized assessment of different systems

System / Characteristics	Web-CALL	IWiLL	BRIX	WSML
Support Multimedia teaching materials	medium	medium	low	high
Support Dynamic lecture presentation	no	no	no	yes
Support Online dictionary	no	no	yes	yes
Support Online exercise	yes	yes	yes	yes
Support listening practice	medium	medium	low	high
Support speaking practice	no	no	no	no
Support reading practice	medium	medium	medium	high
Support writing practice	no	high	medium	high

learning systems: the Web-CALL system, the IWiLL system, the BRIX project, and the WSML system, in accordance with their multimedia features and pedagogical approaches.

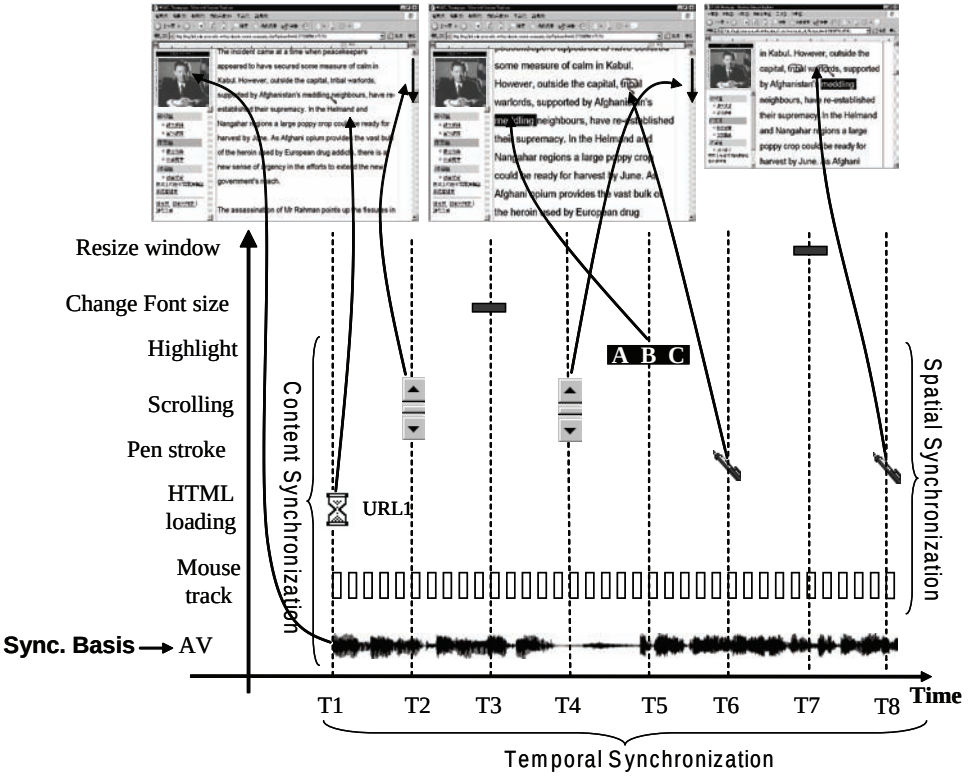
MULTIMEDIA SYNCHRONIZATION

Multimedia systems usually integrate different types of data streams, including continuous media (e.g., audio and video) and discrete media (e.g., text and still image). The synchronization information (i.e., sync-relation) used to render these streams in a correct manner is often interrelated with one another. Thus, multimedia presentation systems must maintain such relations from temporal, spatial, and contextual perspectives and protect them against possible out-of-order and destroyed danger, especially when the streams are going to be presented to end users—the principle of Multimedia Synchronization (Blakowski & Steinmetz, 1996; Effelsberg, Meyer, & Steinmetz, 1993).

In addition, the relations necessary for document presentation may be related to intra-media synchronization (e.g., play audio in continuity without jitter) or inter-media synchronization (e.g., audio-video temporal synchronization in a lip-sync application). In our system, the related media, which include HTML-based document, teacher's voice, and navigation events (e.g., pen strokes, highlight, dynamic annotation, telepointer scrolling, etc.), will be captured during the recording stage. In order to reconstruct the captured process and present the media synchronously, the Adaptive Synchronization Framework (ASF) developed for a better presentation; even the synchronization relations, in particular to the spatial relations, are destroyed by the user interactions/preferences (e.g., font size change, window resize, etc.).

Figure 1 illustrates the handling of synchronization by Adaptive Synchronization Framework. In this scenario, audio is referred to as a presentation time axis (temporal relations) and treated

Figure 1. An example of the integrated synchronized presentation in the WSML system



as a synchronization basis (master stream). The synchronized presentation is described as follows:

T1: The AV and HTML URL1 are loaded at T1. The HTML page is then rendered by the browser and the AV player starts playing the AV lecture at the same time. The mouse-track events would exist all the time during the presentation. Note that the navigation events and the corresponding audio clip should never be presented unless the associated HTML page (namely base page) has been retrieved into the browser, because both navigation-events rendering and audio-clip playing are meaningless if the HTML base slide cannot be loaded successfully (i.e., content synchronization).

T2: A scrolling event is triggered to move down the scroll bar so that the content that is originally out of screen could be displayed. The event is triggered by the teacher during the recording stage.

T3: User enlarges the font size of the document, and the hypertext is subsequently rearranged by the browser.

T4: A scrolling event is triggered to show the content that is out of screen. The event is triggered by the ASF for maintaining content synchronization.

T5: A highlight event over a keyword is invoked at T5.

T6: A pen-stroke event is driven to show a continuous draw effect where the correct coordinates are re-computed by ASF (i.e., spatial synchronization).

T7: At this time, the user narrows the browsing window, and the document layout is changed again.

T8: A pen-stroke event is driven again to show a continuous draw effect. It is rendered according to the correct coordinates re-computed by ASF after the document layout is changed (i.e., spatial synchronization).

IMPLEMENTATION AND FEATURES OF THE WSML SYSTEM

The WSML system integrates audiovisual lectures, HTML slides, and navigation events to provide synchronized presentations. In our environment, teachers use computers to instruct, and a synchronization recorder keeps track of the oral guidance along with several navigation events. The navigation events, such as pen strokes, highlight, dynamic annotation, tele-pointer, and scrolling, are guided media. These media objects and navigated events will be presented dynamically in a browser by using the state-of-the-art, dynamic HTML techniques. In the following, the details about implementation and features of the WSML system will be described. The core of the system includes two perspectives: (1) the synchronized multimedia tutoring and the exercise practice functions for students, and (2) the multimedia lecture-authoring and course management tools for teachers.

For Students

To provide an optimal learning experience for the students, different media objects should be presented synchronously and displayed according to the pre-recorded scenario. In addition, a good exercise system will assist students to have more practices on key points of the lectures.

Voiced Lecture Guidance and Composition Correction

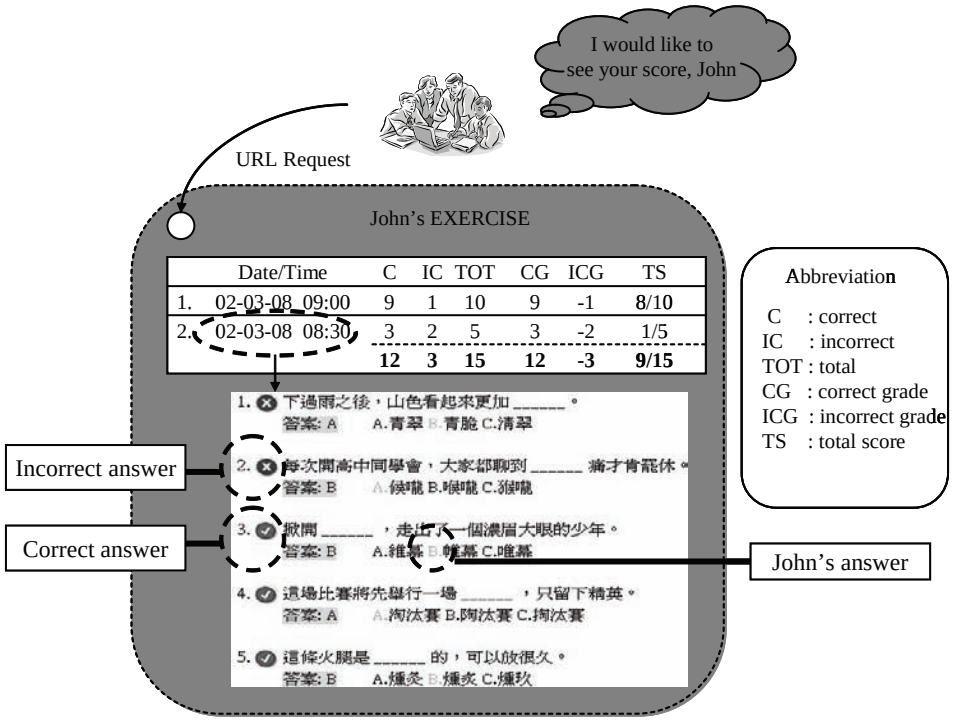
With the authoring tools provided by the WSML system, instructors can record a multimedia document (which may be lecture guidance or a composition correcting results) by navigation events (e.g., mouse moving, annotation, pen drawing, and highlights) and voice, for online access. The function is useful because students can review the multimedia documents again and again. The lecture guidance comprised of recitation with some explanation is a reading enhancement for students. The voice-based composition correction with animated pen-stokes makes students clearly realize what mistakes they made in writing. The function has been applied to online language learning that includes English and Chinese. As Figure 2(a) shows, once a student clicks the play button, he/she can see the composition-correction process completely with the synchronized multimedia presentation. Figure 2(b) shows the voice lecture guidance with tele-pointers and a dynamic dictionary for learning Chinese.

The Online Exercise Function

The online exercise function is designed to evaluate students' learning achievements. Since each student has different degrees of English or Chinese learning, the exercise is categorized into three levels: beginner, intermediate, and advanced level. Three types of exercise—listening exercise, vocabulary testing, and cloze exercise—are provided for students. To a certain extent, each exercise emphasizes different learning goals; for example, listening exercise in intermediate level is different from listening exercise in advanced level. Figure 3 is an example of a Chinese vocabulary test. The following information can be obtained from the exercise function: (1) Students can know how many questions they have answered.

Figure 2. (a) The composition correction with vivid navigation events for learning English; and (b) an example for learning Chinese

Figure 3. The testing results obtaining from the online exercise function



(2) Evaluation results will be given to the student immediately after he or she finishes the test. (3) According to statistical information, students can know what kind of mistakes they made.

FOR TEACHERS

From the teachers' perspective, the WSML system provides several useful multimedia content-authoring tools and a course management tool to create content quickly and manage lectures easily. Moreover, the Web-based exercise management tool helps teachers produce exercise questions more quickly and conveniently.

Multimedia Content Authoring

In the material-authoring stage, this system provides teachers with several tools to facilitate the generation of HTML documents, the recording of oral guidance, and the issuance of some navigation events. These tools include (1) the visualized HTML-editing Tool, and (2) the WSML Recorder.

- **Visualized HTML-editing Tool:** In the WSML system, the most essential teaching media are HTML documents. To enhance the convenience of creating a HTML document, the visualized HTML-editing tool is designed to arrange HTML content visually. Like some commercial editing tools, such as Microsoft FrontPage and Macromedia Dreamweaver, the visualized HTML-editing tool provides "WYSIWYG" features. Teachers can just connect to the WSML Web site and use the online version of the editing tool to generate or manage their HTML documents.
- **The WSML Recorder:** With the prepared HTML documents, teachers can record audiovideo guidance with navigation events by using the WSML Recorder. The recorder consists of three components: a timer, AV encoder, and an event logger. When the teacher starts this recorder, the timer will be initiated to be the timeline of the multimedia document. At the same time, the AV encoder and event logger are also activated to record audio/video data and navigation events, respectively. The recorder detects and stores the synchronization information, including temporal, spatial, and content data, between navigation events and AV lecturing. The navigation events are guided media that are issued by the teacher to emphasize some portions of content or add additional information dynamically. Table 2 shows the collection of navigation events and its description.

Course Management Tool

Having a good course management tool is very important because more and more lectures will be added to the system as time goes on. Additionally, some lectures may need to be updated or modified in the future. For those reasons, we have designed a Web-based course management tool that is described as follows:

(1) Add a new course/lecture: A teacher can manage his or her courses or lectures easily through our system via the Internet. All course information will be recorded in the database (e.g., course, lecture content, teacher's name, etc.). Students can search what they want and need while browsing the lectures. Furthermore, courses and lectures can be classified according to the semesters or course attributes. Students can learn the materials systematically and gradually.

(2) Vocabulary editor: A teacher can first define the vocabularies in the lecture during the recording stage. Through the vocabulary

Table 2. Navigation events and their descriptions

Navigation Event	Description
Audio/Video explanation	Teacher can explain the meaning in a specific sentence and students can practice by imitating the word pronunciation.
HTML Event	Teacher may change the lecture during the instructional process and can add some related reference materials as well as hyperlinks in the lecture.
Scrolling Event	When a HTML document can not be displayed in a viewing window, the scroll bar should be moved to show other portions of content.
Tele-pointer	In the recording stage, teachers often use the mouse to point out the content that they are discussing.
Pen Stroke	The event can simulate strokes of a pen and can be provided for teachers to draw lines or have handwritten effects in the lectures. The result will be presented animatedly in the presentation stage.
Vocabulary Note	A teacher can define the vocabulary appearing in the lecture. The defined vocabularies will become an online dictionary when the students navigate or browse that word. The online dictionary includes the vocabulary explanation, an example, and the pronunciation.
Highlight	The event is useful for teachers to highlight some important words or sentences in the lecture. It is the most frequent feature used to put emphasis on a HTML document.
Dynamic Annotation	To supplement some information, the WSML Recorder also allows teachers to add some textual data dynamically.

editor, the teacher can add the explanation and example sentences of vocabularies and record the pronunciation of vocabularies.

Exercise Management Tool

The exercise management tool provides an easy-to-use authoring interface for exercise creation. The authoring function in the exercise management tool includes the creation of new exercise and re-authoring an exercise. In current stage, several kinds of exercises, such as listening exercise, vocabulary testing, and cloze exercise, have been designed to support specific lecture material. As shown in Figure 4, authoring a cloze exercise is designed to support the understanding in reading a Chinese newspaper.

CONCLUSION

In developing and testing the WSML system for its online use, we consulted many ESL teachers with experience in the Computer Assisted Language Learning (CALL) field. We were delighted to discover that they are happy with the features and existing performance of the WSML system. The easy-to-use lecture-capturing tool and vigorous presentation feature of the WSML made teachers' teaching and homework correction more efficient and effective and more enjoyable, not only for teachers themselves, but for their students. More interesting, multimedia-based lecture presentation increases students' learning motivation and, most important of all, students more clearly understand what mistakes they have made in their homework and why. To this end, the WSML system has been a very helpful online

language tutor in our school. The result of this study is essentially a framework, applicable to different foreign language learning and different teaching scenarios. We hope that the proposed WSML framework will be beneficial for other e-learning applications to explore multimedia relations possibly involved in any teaching activities, and so to develop more effective and useful systems for students' learning.

KEY TERMS

Adaptive Synchronization Framework (ASF): A framework that adopts a mechanism to re-compute the synchronization relations that are destroyed by unexpected events (e.g., window resizing or font size change), so as to restore a presentation system to synchronization.

AV Encoder: An encoder used to encode the input audio/video signal to specific digital format.

Computer Assisted Language Learning (CALL): The topics discuss the teaching practices and research related to the use of computers in the language classroom.

Event Logger: A text file used to record the timestamps, attributes, and types of navigation events invoked by the teacher during the recording stage. The log is treated as synchronization information for dynamic presentation.

Multimedia Synchronization: Multimedia systems usually integrate different types of data streams, including continuous media (e.g., audio and video) and discrete media (e.g., text and still images). The information (e.g., temporal, spatial, and content relations) for displaying these data streams is often interrelated. Thus multimedia systems must guarantee such relationships between streams against partial loss or being nonfunctional when the streams are transmitted after capture and presented to end users.

Navigation Events: The events, such as pen stroke, tele-pointer, document scrolling, annotation, highlights, and the like, invoked by the teacher during the recording stage will be captured as guided media and thus can be presented dynamically to the end users.

Timer: The timer is used to determine timestamp of navigation events invoked by the teacher during the recording stage.

Chapter 5.5
Teaching, Learning and Multimedia

Loreen Marie Butcher-Powell
Bloomsburg University of Pennsylvania, USA

ABSTRACT

"We must not forget that almost all teaching is Multimedia" (Schramm, p.37). Today, the magnetism of multimedia is clearly oblivious via the use of streaming video, audio clips, and the Internet. Research has shown that the use of multimedia can aid in the comprehension and retention of student learning (Cronin & Myers, 1997; Large Behesti, Breulex & Renaud, 1996; Tennenbaum, 1998). As a result, more educators are utilizing Web-based multimedia materials to augment instruction online and in the classroom. This chapter provides a theoretical framework for transforming Student Centered Discussion (SCD), a traditional based pedagogy strategy, to a new multimedia pedagogy SCD strategy. The new multimedia SCD pedagogy represents a new way of teaching and learning. As a result, positive responses and feedback have been collected from students in their ability to interpret facts, compare and contract material, and make inferences based on recall of information previously presented or assigned in article readings.

INTRODUCTION

Research has shown that students can integrate information from various sensory modalities into a meaningful experience. For example, students often associate the sound of thunder with the visual image of lightning in the sky. When the cognitive impact of two given interaction modalities differ enough, different learning modes can be induced. Moreover, an interaction modality, which affects a learning mode, also has consequences for the learning performance (Guttormsen, 1996, 1997). Therefore, a teacher is faced with the need to integrate various combinations of sensory modalities, such as text, still images, motion, audio, animation, etc., to promote the learning experience.

Multimedia is multisensory; it engages the senses of the students. Multimedia can be defined in a variety of ways, but in this chapter, the term "multimedia" refers to a Web-based interactive computer-mediated application that includes various combinations of text, sound, still images, audio, video, and graphics. Multimedia is also interactive; it enables both the student and the

teacher to control the content flow of information (Vaughan, 1998). A major part of using multimedia in instruction involves engaging students in sense-making activities, such as conversations and chats about external representations that use concepts, symbols, models, and relationships. As a result, multimedia has introduced important changes in the educational system and has impacted the way teachers communicate information to the student (Neo & Neo, 2000).

Learning

Learning is fundamentally built up through conversations between persons or among groups, involving the creation and interpretation of communication (Gay & Lentini, 1995; Schegloff & Sacks, 1973; Schegloff, 1991). More importantly, learning is established and negotiated through successive turns of action and conversations (Gay et al., 1995; Goodwin & Hertage, 1986; Schegloff, 1991). Thus, conversations are means by which people collaboratively construct beliefs and meanings as well as state their differences.

Brown, Collins, and Duguid (1989) argued that learning involves making sense of experience, thought, or phenomenon in context. They hypothesized that student representation or understanding of a concept is not abstract and self-sufficient, but rather it is constructed from the social and physical context in which the concept is found and used. Further, Brown et al. (1989) emphasized the importance of implicit knowledge in developing understanding rather than acquiring formal concepts. It is, therefore, essential to provide students with authentic experiences with the concept.

Students can engage in learning conversations in distributed multimedia environments. Multimedia technologies, such as graphics, simulations, video, sound, and text, allow instructors to use multiple modes and representations to construct new understanding and conceptual change of enhancing student knowledge. Brown et al. (1989) stated that learning involves making sense of thoughts, experiences, or phenomena in contexts. Multimedia allows for the accommodation of diverse learning styles. Different media provide different opportunities for communication and activities among students. For example, online conversations provide a common background or mutual knowledge about beliefs and assumptions during conversation.

The Distinct Ways of Learning

There are multiple ways of learning. Four of the most common and distinct ways to learn are independent learning, individual learning, cooperative group learning, and collaborative group learning (Kawachi, 2003). For the purpose of this chapter, it is important to understand the differences between cooperative and collaborative learning.

Traditionally in a cooperative learning environment, knowledge is learned by the student via the teacher or other students repeating, reiterating, recapitulating, paraphrasing, summarizing, reorganizing, or explaining the concepts. Meanwhile, in collaborative learning, knowledge is not learned by the student via the teacher, but rather knowledge is learned via an active dialogue among students who seek to understand and apply concepts. Using multimedia in collaborative environments allows students to participate in genuine learning activities by which they can reflect as well as modify their understanding of concepts (Brown et al., 1989; Gay, Sturgill, Martin, & Huttenlocher, 1999; Harasim, Hiltz, Teles, & Turoff, 1995; Wegerif, 1998; Murphy, Drabier, & Epps, 1997). The ability to read and respond to a message posted to an online forum creates opportunities for the creation of knowledge.

With the use of multimedia, students can utilize the information presented to them by the teacher, and represent it in a more meaningful way, using different media elements. Fortunately, there are many multimedia technologies that are available for teachers to use to create innovative

and interactive courses. A review of literature on multimedia educational tools revealed some interesting innovative and rich multimedia-based learning tools. Jesshope, Heinrich, and Kinshuk (n.d.) researched the ProgramLive application. The ProgramLive application is a rich multimedia-based tutorial of the Java programming language. ProgramLive's interface represents a notebook, within a browser. There are tabs to the side of the notebook display that can be used for navigation of the material, as well as pop-up explanations of key concepts.

Millard (1999) developed an Interactive Learning Module for Electrical Engineering Education and Training titled the Interactive Learning Modules (ILM). ILM presents Web-based multimedia tutorials created with Macromedia Director. ILM provides a mechanism for the creation of supplementary material for lectures and collaborative problem solving and simulation environments. ILM is highly modular for the usage of various materials to be used in multiple courses. Similarly, the Multimedia Learning Environment (MLE) developed by Roccetti and Salomoni (2001) is a networked educational application that also provides course material in a student-based manner. MLE provides a virtual learning environment, through a client application, where the multimedia educational material is structured in Adaptive Hypermedia, from which sets of hypermedia pages are dynamically retrieved and presented to the student via tailoring the contents and presentation style to the students needs (Roccetti et al., 2001).

Further, Jesshope, Heinrich, and Kinshuk (n.d.) are currently developing an integrated system for Web-based education called the Teaching Integrated Learning Environment (TILE). This system uses Web-based delivery of course material, including interactive multimedia presentations, problem solving, and simulation environments in which students learn by doing. Like MLE, TILE provides students with an interactive multimedia environment and instructors with a multimedia environment for managing, authoring, monitoring, and evaluating student learning.

The multimedia educational tools, described above, have been traditionally used in two ways, either as a vehicle for students to learn theory and application beyond the subject matter or as a tool used by the teacher to support teaching. As a result of multimedia educational tools, teachers are faced with a significant need to provide a more multimedia-based approach to learning, and to create a new educational pedagogy that emphasizes collaborative learning via multimedia.

Numerous studies have been conducted in the attempt to determine how effective multimedia is in teaching (Blank, Pottenger, Kessler, Roy, Gevry, Heigel, Sahasrabudhe, & Wang, 2002), however, very few studies have been conducted to illustrate and determine the factors that may aid in a new multimedia pedagogy strategy for teaching. This chapter was designed to provide the theoretical framework for how teaching is enhanced using Web-based multimedia. The objective of the chapter will be to explain the latest pedagogical teaching strategies for utilizing interactive Web-based multimedia educational tools. As a result, this chapter will provide instructors with a positive and effective example for utilizing Web-based multimedia in teaching.

A NEW GLOBAL ENVIRONMENT FOR LEARNING

A new multimedia pedagogical model for learning in a collaborative environment was incorporated in the Information Science and Technology (IST) undergraduate program at Pennsylvania State University (PSU), Hazleton, Pennsylvania (USA). The transformation from a traditional lecture-based model to an interactive Web-based multimedia application was accomplished using A New Global Environment for Learning (ANGEL). ANGEL is PSU's course management system (CMS) that is currently in use within the University's system

(Pennsylvania State University, n.d.). ANGEL is an interactive Web-based multimedia application developed by CyberLearning Labs Incorporated, for constructive, collaborative, inquiry-based, and problem-solving Web-based learning. ANGEL allows for interaction, testing, presentations, audio, video, forums, file submissions, and many more multimedia features. Through ANGEL, instructors are able to use multimedia effectively in aiding in the students' learning and retention process (Pennsylvania State University, n.d.).

Pedagogical Strategy

Beginning with the philosophy that "learning is not a spectator sport" (Chickering & Gomson, n.d.), students are encouraged to get involved in their educational experience. The probability of students' learning improving by getting involved, talking and writing about what they have learned, relating it to past experiences, and most importantly applying it to their daily lives, is much greater than by students sitting in classes listening to teachers, memorizing prepackaged assignments, and spitting out answers. The goal of each course is to provide the students with a challenging, critical thinking, novel, technology-focused, and learner-centered educational experience, where they learn by pursuing knowledge, improving basic communication skills, and, most importantly, taking responsibility for their own learning (Brown et al., 1989).

To obtain such a goal, the following procedures were used. The classes were structured toward creating a problem-based learning (PBL) and a student-centered discussion (SCD) environment for students utilizing a multimedia course management system, ANGEL. PBL is traditionally used in courses that provide more student-centered learning experiences. The origins of PBL began in the medical education field (Barrows, 1986, 1999). PBL is a student-centered pedagogical approach in which learning is taught through suggested real-world problems. PBL establishes the importance of clearly formulated effective real-world problems. An effective problem has a realistic context and is couched in appropriate vocabulary. The problem should be complex and ill-structured, without clear-cut, easy answers or nuances and subtitles that are not immediately apparent. Moreover, the problem should support both discovery and self-directed learning while engaging the interest and the curiosity of the student (Desmarchais, 1999).

SCD is a delivery system for the application of educational goals in the classroom. This process is accomplished by integrating basic discussion skills in the classroom. The technique is one that models after all competency levels of Blooms Taxonomy in a limited structured time period. The discussion and team-building process that occurs in SCD promotes the active engagement of the students in their own educations. This technique requires the student to actively take responsibility for conducting a productive and meaningful discussion (Wright & Shout, n.d.). SCD has been proven to be an interactive model that encourages students to develop effective communication and interpersonal skills as well as strengthen critical-thinking skills (Butcher-Powell & Brazon, 2003). Moreover, Wright et al. (n.d.) stated that this model is effective regardless of discipline or knowledge base.

The addition of multimedia technology into a PBL and a SCD environment further enhances the students' learning experience. Figure 1 illustrates this focus.

Class Structure

The original version of the PBL and SCD was modified in order to incorporate multimedia into the class. The classes meet every Tuesday and Thursday for approximately one hour and 10 minutes for one 15-week and one 14-week semester. On every Tuesday, the PBL and SCD models were used in class. To accomplish a cohesive learning experience, the students are first divided into small

groups consisting of four students. Each group has 30 minutes to discuss, ponder, debate, question, learn, and solve the problem from a video clip stored on ANGEL. Additional resources, such as articles, notes, and existing Web cases were made available to the students in a digital library on ANGEL. After the 30 minutes were over, the entire class was combined into one big circle, upon which students received another video clip that expanded upon the first video clip. The students were to engage in a larger PBL and SCD environment to create a solution to the problem identified in the video clips.

After the class session was over, students were required to log on to ANGEL and write a brief summary of what they learned from the video clips, and how that relates to their lives. In addition, the students were required to search the Web and find an article on the subject matter and post it to ANGEL for Thursday's class. On Thursday, an interactive PowerPoint lecture supporting Tuesday's video clip and the students' PBL and SCDs were presented to the class and remained available in ANGEL for later student usage. After the 30 minute lecture, the remaining 40 minutes were left for the students to find and discuss an article or Web site in the forum section of ANGEL. Moreover, each student was also required to read and elaborate upon at least one other student's summary of a related article or Web site.

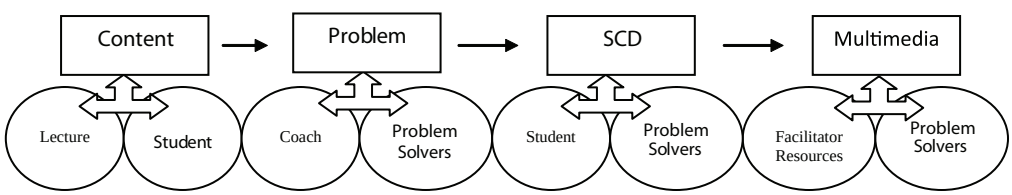
After the material was taught utilizing the defined methods, the students were required to take an online interactive time test via ANGEL. Traditionally, the test consisted of random multiple-choice, true and false, matching, and short-answer questions. ANGEL allowed authenticated users, during a specified time frame, various combinations of questions, and timed the test. More importantly, ANGEL allowed the teacher to make prerecorded video available during the test in order to guide a student through each excursion of the test. And, finally, ANGEL allowed the teacher to pregrade the test so that the students had immediate access to their grades after their tests were submitted. However, the answers to the test were only available for review after all students completed the test.

As illustrated above, this new multimedia pedagogical strategy allowed for inquiry to be accomplished via text mining and visualization tools. As a result, students were able to explore the emerging problems, solutions, and trends in their fields of study. Moreover, collaborative learning was also achieved via live links and remote-controlled "video" sessions by reviewing multimedia recorded lecture sessions that encouraged students to interact with instructors and digital libraries.

Data Source and Collection Instrument

The data population consisted of undergraduate students (n = 32) in the Information Science and Technology major at PSU Hazleton, Pennsylvania, USA. The students ranged in age from 20 to 28 (M = 20.51, SD = 2.68). Academic classification was represented by juniors (n = 26) and seniors (n = 8). The teaching team consisted of one instructor utilizing two classes to explore student

Figure 1: The multimedia PBL–SCD curriculum model



perceptions and experiences with the cohesive multimedia pedagogical strategy. Data were gathered in pre- and postquestionnaires and in student diaries. The pre- and postquestionnaires consisted of 11 questions to assess the students' interest in group project work and whether or not they were motivated in their project development. The questionnaire also tried to determine the students' levels of understanding and critical-thinking skills. The questionnaire was measured using a five-point Likert scale. The scale measurements were 1, strongly agree; 2, agree; 3, undecided; 4, disagree; and 5, strongly disagree. The scales and all questions in the questionnaire were developed after a review of literature guided by the theoretical base. An expert panel of faculty and doctoral-level graduate students evaluated the face and content validity of the questionnaire.

RESULTS AND DISCUSSION

The feedback at the time of writing indicates that the new multimedia pedagogy approach used in the classes is fully endorsed by students and leads to intense student engagement and an effective level of learning. Thus, over 80% (87.7%) of the students ($n = 32$) had a computer with Internet access at home and were able to fully take advantage of the new multimedia way of learning. At the beginning of the course, most (90.6%) of the students were excited and eager to be taught using the new multimedia pedagogy. Furthermore, almost all of the students (96.87%) at the end of the course felt they had learned a great deal of theory, content, and application with the new multimedia pedagogy. Consistently, students (96.87%) indicated that they would like to see this new multimedia pedagogy applied to all of their undergraduate classes. The perceived benefit of the new multimedia pedagogy to the student mean was 1.92 ($SD = 0.63$). This indicated that students agreed with the perceived benefits of the new multimedia pedagogy strategy.

Inferential *t*-tests were used to determine if significant differences ($p < 0.05$) existed in the perception of additional workload as a result of the adoption of the new multimedia strategy. The *t*-test revealed that no significant differences ($t = 1.59$, $p = 0.114$) existed in the additional workload mean between the students who liked and did not like the new multimedia way of learning. Furthermore, no significant differences existed in the additional workload mean between the students who earned a B or better and the students who earned a B- or less. More importantly, no significant differences existed between the students who earned a B or better or the students who earned a B- or lower, as they strongly agreed that this was a great way to learn.

Moreover, the students' experiences with this new multimedia pedagogical strategy were also demonstrated throughout the semester by the student's ability to interpret facts, compare and contrast material, and make inferences based on recall of the information previously presented or assigned information in the given article. Most importantly, the student's readiness for the class was instantly recognized.

Overall, the new multimedia pedagogical strategy represents a new way to develop and deliver classroom discussions and material. In traditional classroom discussions, the faculty member assumes the role of the discussion leader. He or she identifies the questions that will be discussed and maintains a teacher-centered structure. In contrast with traditional classroom discussions, the new multimedia pedagogical strategy online approach is much more student-centered through the usage of multimedia enhancements. As a result, the instructor assumes the role of discussion facilitator, instead of discussion leader. This shift from discussion leader to discussion facilitator forces students to become responsible for their behavior and interaction in the discussion.

Limitation

The integration of multimedia into the classroom and online is essential if multimedia is to become a truly effective educational resource. However, the integration and the change in pedagogy are difficult, time consuming, and resource-intensive tasks. Research has shown that teachers need time working with the technology before they will be at a level of comfort to change or modify their pedagogy (Redmann et al., 2003).

CONCLUSIONS

Despite a rapidly growing recognition of the potential impacts of such interactive multimedia developments, teachers have relatively little understanding of the extensive benefits surrounding the use of new multimedia resources in the classroom. The dearth of knowledge exists in a wide variety of domains, including but not limited to the design and development of new systems and tools to retrieve and manipulate documents, as well as the uses and impacts of such new tools on both learning and problem solving. Previous research documents the improvement in learning as a result of the use of multimedia (Blank et al., 2002), while other researchers have not found any significant differences in learning between multimedia-based and traditional-based pedagogical approaches (Moore & Kearley, 1996). As efforts to illustrate the impact of multimedia in instruction continue, one fact remains: Modern multimedia-based pedagogical approaches have roots of the oldest traditional human communication methods. However, in the future, multimedia pedagogical strategies will have a much more profound impact on how instructors approach and engage students in the process of education and communication.

As the complexity of using multimedia in the classroom continues, new teacher and student technologies will become robust, and ad hoc methodologies will give way to more interactive student competence for learning.

Chapter 5.6
Interactive Multimedia for Learning and Performance

Ashok Banerji
Monisha Electronic Education Trust, India

Glenda Rose Scales
Virginia Tech, USA

ABSTRACT

Developments in information and communication technologies (ICT) are rapidly transforming our work environments and methods. Amongst these changes, the advent of interactive multimedia technology has meant new approaches to instruction, information and performance support implementations. The available resources can be amalgamated in a suitable way to create an enabling environment for learning, training and performing. Concise descriptions of the salient aspects are presented along with basic design principles for communication and performance support. Guidelines for design and suggestions for implementation are provided for the benefit of the practitioners.

INTRODUCTION

Undoubtedly, the advent of computers and communication technology has forever changed our daily lives. Today, we have the fantasy amplifiers (computers), the intellectual tool kits (software and hardware), and the interactive electronic communities facilitated by the Internet that have the potential to change the way we think, learn, and communicate. However, these are only tools. The late Turing Award winner Edsger Dijkstra said, "In their capacity as a tool, computers will be but a ripple on the surface of our culture. In their capacity as intellectual challenge, they are without precedent in the cultural history of mankind" (Boyer et al., 2002). The onus is on us, our innovative ideas as to how we harness the technology for education, training, and business

in order to lead or lag in the new social order. In this regard, we may remember that Charles Darwin said, "It's not the strongest of the species who survive, nor the most intelligent, but the ones most responsive to change."

In this chapter, we will review these current developments in teaching and learning from a broader performance support systems perspective. Then we will suggest a performance-centered design approach in support of developing teaching and learning solutions for the knowledge worker of today.

Lessons from the Past

There are many examples from the past indicating the rush to implement cutting-edge technologies (Marino, 2001). All of these began with a grand promise as a total solution to a long-standing problem. For example, in 1922 Thomas Edison predicted that "the motion picture is destined to revolutionize" the educational system and will largely supplement textbooks. Radio was hailed with the promise to "bring the world to the classroom." Similarly, educational television was touted as a way to create a "continental classroom" (Cuban, 1986). How much of these hopes have been met as of today?

On similar lines, recently, there has been much hype about interactive multimedia and the Internet as the remedies for all problems in training and education. However, as a knowledge resource, multimedia productions, the Internet, and a library have similar attributes. It is particularly wrong to assume that putting all the information on the Internet will make learning happen. The Internet is useful, but it does not guarantee learning any more than a good library ensures creating knowledgeable persons (Clark, 1983).

From a technocratic perspective, there is a tendency to assume that installing computers and networks will solve every conceivable problem. However, the value and benefits of technology will come only through leveraging it for dynamic and strategic purposes that place the focus first on learning and performing and second on the technology (Dede, 1998; Bare & Meek, 1998).

The key lessons from the past indicate that including performance-centered design techniques tends to improve the usability of the information or learning systems. As we move from the "Information Age" into the "Knowledge age," it is important to consider technological solutions to support teaching and learning (Reeves, 1998). In the transition from the "Old Economy" to the "New Economy," a key outcome of the transformation is a dramatic shift from investments in physical capital to investments in human or intellectual capital. A well-designed holistic approach toward training and development is therefore needed to support the learning needs of the knowledge worker (McArthur, 2000). In this regard, we need to consider the benefits of a user- and performance-centered approach from the standpoint of design. The remaining portion of this chapter will discuss how the electronic performance support systems approach can help in the challenges associated with the new paradigm.

PERFORMANCE SUPPORT SYSTEMS

There are three primary impacts of information and communication technologies (ICT). These are the methods in which the following occur:

(a) Information is distributed and retrieved.
(b) Knowledge and expertise are stored and acquired.
(c) Skills are learned and transferred.

These technologies have made important impacts in transforming education, training, and skill development approaches. In 1991, Gloria Gery introduced a framework for electronic support (Gery, 1991, 2002). While definitions vary, it is widely agreed that performance support systems do the following:

- Enable people to perform tasks quickly, because they provide integrated task structuring, data, knowledge, and tools at the time of need
- Do not tax the performer's memory or require performers to manipulate too many variables
- Enable task completion, with learning as a secondary consequence

Taking a broader view, we can say that an electronic performance support involves "a human activity system that is able to manipulate large amounts of task related information in order to provide both a problem solving capability as well as learning opportunities to augment human performance in a job task" (Banerji, 1999a). Such systems provide information and concepts in either a linear or a nonlinear way, as they are required by a user. The EPSS concept provides a holistic design framework encompassing a custom-built interactive guidance, learning, information, and knowledge support facility that is integrated into a normal working environment. Such systems are concerned with effective human–task interaction in which the computer provides an interface to various job tasks and becomes an aid in achieving efficient task performance.

Components and Types of EPSS

In most modern workplaces, computers are used for decision making, task performance, task sequencing, planning, and also learning, thereby replacing many manual methods. In such situations, the work is not done solely by people or solely by computers but by human-computer systems. The computers and communication technology thus act as a powerful tool by providing an interface to the basic job tasks that are involved. People and computers thus tend to work cooperatively and symbiotically, combining the advantages of the powers of each in order to achieve more effective job performance (Licklider, 1960).

Thus, human-task interaction within the human activity system (HAS) forms the foundation of EPSS. The HAS involves the following three subsystems, as shown in Figure 1:

(a) The tool subsystem
(b) The task subsystems
(c) The people subsystem

The tool subsystem provides an interface to various job tasks and becomes an effective aid in achieving efficient task performance. It can also be a means for improving performance. However, the performance generally gets hindered in the absence of an appropriate "interface." These are the barriers of task performance that a support system should strive to minimize. The dimensions of these barriers include knowledge, skill, information, decision, processes, and procedures. The function of an EPSS would be to reduce the "permeability" of the interface through appropriate means. These include eLearning facility and Knowledge Management, among many others (Dickelman & Banerji, 1999).

There could be three principal ways in which the "tools system" interfaces the "task system," and, three broad classifications of EPSS can be made depending on how they render support in task performance:

Type 1: In this type, tasks are performed with computer and software tools, such as word processors, spreadsheets, and so on. Support for this type of application is tied with the software tools and, therefore, can be called *software-integrated EPSS*. The simplest examples are cue cards, animated help in Microsoft applications (Figure 2), and wizards.

Type 2: In this type, computer-based tools mediate the organizational tasks and practices, such as banking systems, enterprise resource planning systems, air ticket booking, along with hotel and car booking systems, and so

Figure 1: Concept map of human activity system

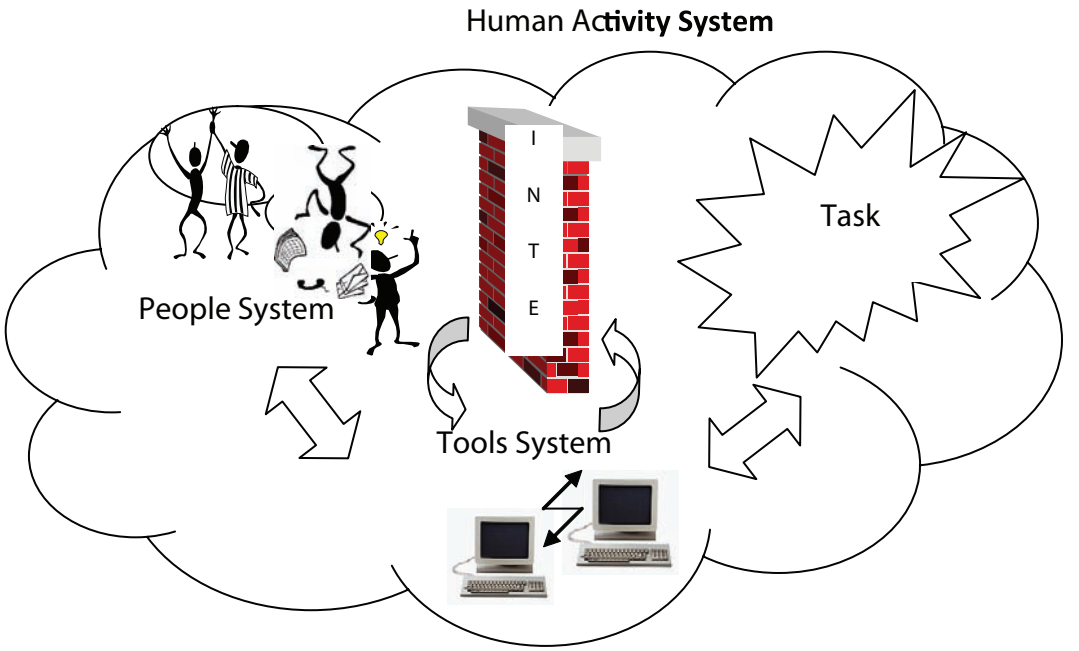

Figure 2: Animated help in Microsoft applications

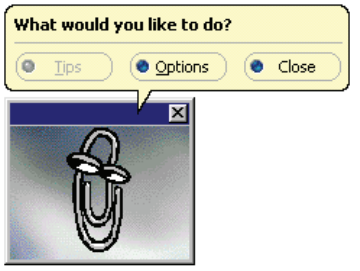


on. Supports are needed as an integrated part of this type of application so that the user can perform competently with minimal training. These types of applications can be called *job-integrated EPSS.*

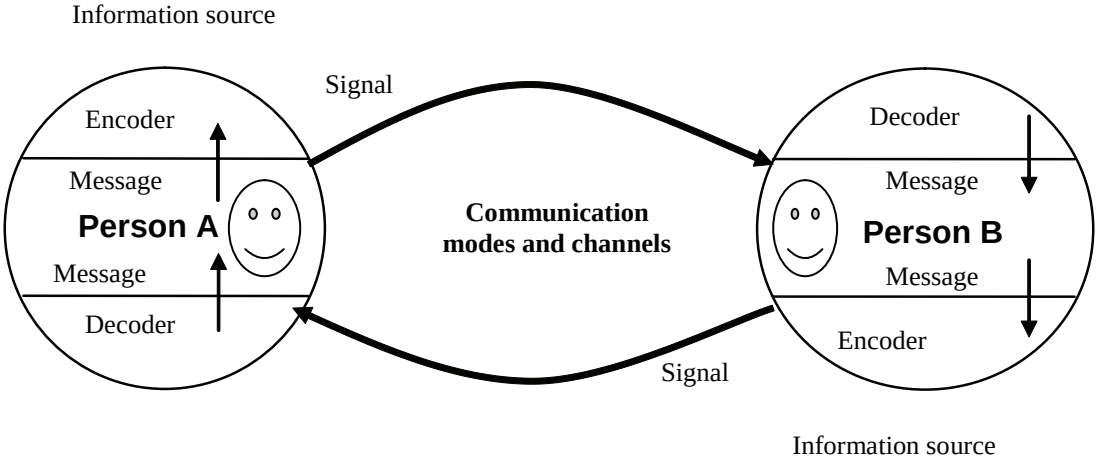
Type 3: In this type, computer-based systems mediate and facilitate the various operations and job roles, such as knowledge-based tasks, repair and maintenance jobs, and so on. Support for this type of application can be called *operation-integrated EPSS.* The emerging technologies involving wearable computers and virtual reality applications supporting repair jobs fall in this class of applications.

Numerous examples of EPSS applications are available in the literature (Banerji, 2003; Dickelman, 2001; Gery, 1991; Hall, 2003). However, detailed discussion of specific EPSS tools is not possible within the confines of this chapter.

INTERACTIVE TECHNOLOGIES FOR COMMUNICATION

Let us now examine multimedia technology as a tool for communication and information transfer. Communication is central to the development of human society and is responsible for all the knowledge that we have accumulated so far. By the word "communication," we mean the process of transmission of data and information from one person to another, which ultimately may lead to knowledge after processing in the mind of the recipient.

Figure 3: Encoder-decoder and channel model of communication



The communication process for information transfer is usually bidirectional. The chain of events starts with a trigger in the mind of the sender (Person A), who, in turn, gives the idea a form by encoding it in a language or expression or picture. The encoded message (signal) is then transmitted to the receiver (Person B), who must have the appropriate decoder to understand the message conveyed by the signal. The receiver may appropriately respond by similarly returning a message to the sender after suitable encoding.

The process of communication, however, continues only if the receiver has the appropriate decoder/encoder. This model is shown in Figure 3. This model can also be easily modified for human–computer communication by replacing "Person B" in the model with a computer. The developments in multimedia and Internet technologies provided the necessary impetus for this evolving human–computer symbiosis utilizing the various communication modes and channels. Their possible applications are limitless, as the technology is under constant evolution.

In the case of human-computer communication, interaction with the computer and the communicative dialogue takes place through some limited modes and channels. The modes are mainly visual, audio, and tactile. Within each mode, there can be various channels. Examples include text, graphics, animation, and video channels in visual mode; voice, sound, and music in audio mode; discrete and continuous tactile interaction modes using keyboard and mouse/joystick, etc. The effectiveness of this communication depends on how well the modes and the media components have been selected and combined. Various interactive technologies are available for this purpose. Detailed discussion on these will be beyond the scope of this chapter. However, the above model is important for conceptualizing and realizing the three types of EPSS discussed earlier.

DESIGN PRINCIPLES

The foregoing discussions on human–task interaction and interactive technologies for communication give us the necessary foundation for appropriate design of interactive multimedia for learning and, particularly, for performance support. Although the complexity of the application domain can vary considerably, we can design an appropriate performance support solution based on a set of 10 fundamental principles and guidelines. These are listed in Table 1. The 10 basic principles formulate the design strategies

Table 1: Basic principles of performance support

Number	Principle	Remarks
1.	**Specify and prioritize** the critical areas of underperformance within the application domain and then **identify appropriate strategies** to improve performance	Suggests a methodology for identification of critical areas of performance deficiency and a top-level approach for their remedy
2.	Attempt to **design mechanization aids and automation tools** to facilitate increases in personal and organizational performance with respect to task-oriented skills	Possible measures for prioritizing tasks could be based on cost, quality, error rate, and task performance time
3.	Identify relevant **generic and application-oriented tools and processes** that will provide on-the-job support and improve task performance	
4.	Attempt to identify and, if possible, eliminate all unnecessary **information blockages and constrictions** within an organization or a work environment	Suggests generic tool sets for information provision, information dissemination, intervention of JIT
5.	Identify an appropriate **combination of media, multimedia, hypermedia, and telecommunications in** order to optimize information flow and interpersonal communications	Training and learning facilities, including eLearning, within a performance support environment
6.	Where a user or employee has an identified skill deficiency, attempt to rectify the situation using **just-in-time (JIT) training and learning techniques**	
7.	Whenever feasible, a performance support system should accommodate **individual learning styles** and thus attempt to maximize its utility for as wide a range of users and task performance situations as is possible	Accommodates the importance of various types of users and their learning styles
8.	Identify appropriate groups of people who have the expertise needed to solve demanding problems and provide the infrastructure necessary to **facilitate group working**	Suggests computer-supported collaborative work (CSCW), the use of intelligent agents, and Knowledge Management
9.	Whenever feasible, attempt to use **intelligent agents** within an EPSS facility in order to **(a) identify the skills needed** for a given task, **(b) locate sources of organizational expertise** relevant to these tasks, and (c) enhance software components	
10.	Attempt to provide facilities to **create a corporate pool of knowledge and skill assets** that can be used to maintain and enhance performance levels	Permeate benefits of performance support right across an organization; create a corporate knowledge pool and skill asset (knowledge capital) that can be made available throughout an organization and is available when needed

for EPSS, including its major supporting components—eLearning and knowledge management (Banerji, 1995).

IMPLEMENTATION APPROACH

Performance means to complete a task such as a piece of work or a duty according to a usual or established method. It also means mastering the task using the most efficient and effective techniques. One aspect of mastering a task using a performance support system is the reliance upon the cognitive partnership between the user and the performance support tool. The important functions and performance measures are as follows:

(1) Reduction in task performance time
(2) Reduction of operational error
(3) Improvement of the quality of task performance
(4) Reduction in cost

These can be achieved through appropriate design of EPSS (Barker & Banerji, 1995; Banerji, 1999a; Gery, 2002).

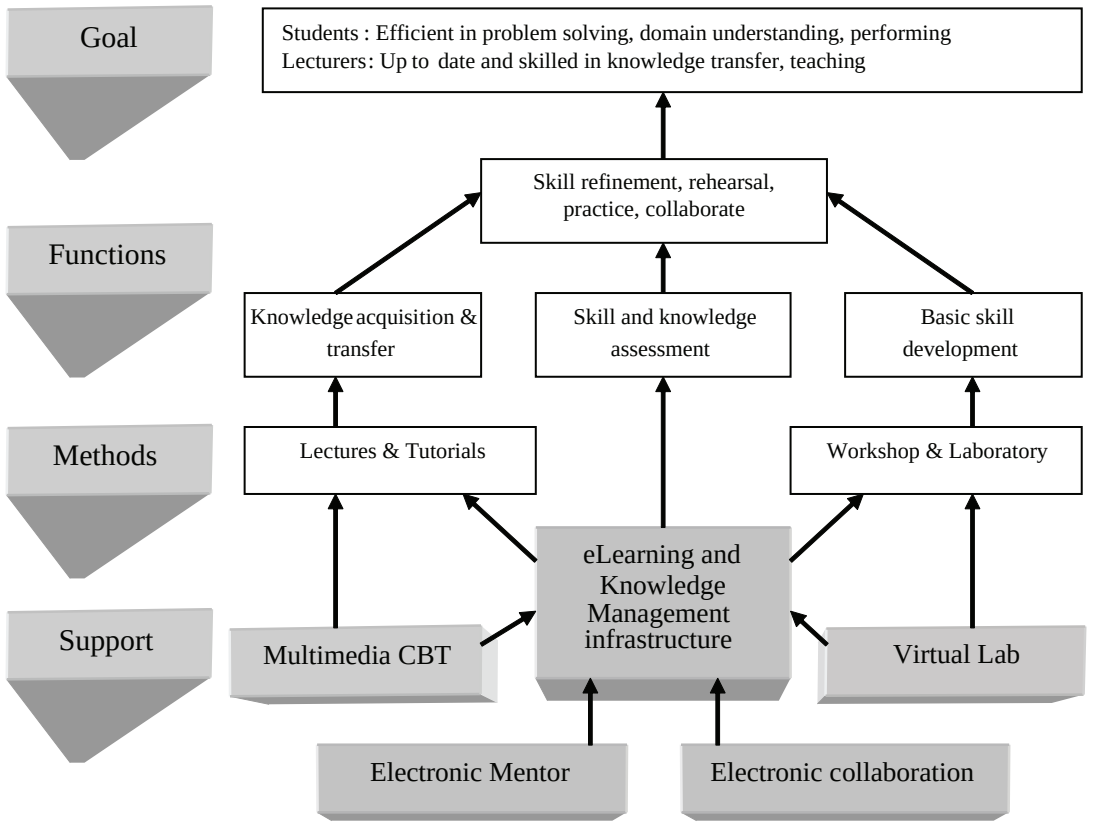
EPSS for Teaching and Learning

The four parameters, time, error, quality, and cost, form the justification for the use of the EPSS approach in any workplace design/redesign. For example, these are equally applicable in any academic institution or corporate university for supporting (a) the students in their learning tasks, (b) the faculty in their tasks of delivering knowledge, and (c) the employees in their management tasks and functions. Let us elaborate one approach.

Despite the advent of powerful, inexpensive, easy-to-use computer technology, the uptake of computer-assisted learning and computer-based training methods within most academic institutions had so far been slow. However, a new wave in the form of *Virtual Classroom*, *Virtual University*, *Web-Based Training* is currently sweeping across most institutions all over the globe. These are clubbed under the term eLearning (or e-learning), which provides opportunities for new modes of information exchange, information transfer, and knowledge acquisition.

It is conceivable that for some time to come, lectures will continue to be the mainstream mechanism for the bulk dissemination of information and knowledge to large groups of students. Given this situation, it is important to address the issue of how best to leverage technology to improve the quality of students' learning experiences and at the same time provide a more effective and efficient framework for the faculty to develop and present

Figure 4: Concept map of support system for teaching and learning



material. One way in which this could be done is to create an electronic performance environment that simultaneously fulfils the needs of both faculty and students. The model of required support for this purpose is shown in Figure 4.

The model shown in Figure 4 is based on the recognition of the currently accepted strategy. It suggests how we can incorporate the new strategy in making the shift (a) from teacher-centered instruction to student-centered learning, (b) from information delivery to information exchange, and (c) from passive learning to active/exploratory/inquiry-based learning.

The distinguishing characteristic of knowledge and skill is that it derives from and finds its meaning in activity. Knowledge is dynamic. Its meaning is constructed and reconstructed as the individual grapples with the use of knowledge through conceptualization, analysis, and manipulation. This naturally has important implications for curriculum development. The objectives of education in any discipline are conventionally attained through (a) classroom training (conceptual understanding), (b) tutorials (analysis), and (c) laboratory practice (practical skill or manipulation).

However, in view of the rapidly changing practices, revitalizing education and training, particularly technical education, has become a matter of concern. This is because of two factors. First, setting up an appropriate up-to-date laboratory is costly and takes time. Second, accessibility of the laboratory is limited to fixed available hours. The existing practices therefore do not support open and flexible learning (Barker, 1996; Baker et al., 1995). Therefore, the central challenge lies in how to provide cost-effective learning opportunities for a larger and more diverse student population. Following on the human activity system model (Figure 1) and the basic principles of performance support system design (Table 1), Figure 4 suggests an approach for a support system for teaching and learning. This can be achieved by incorporating the virtual laboratory, multimedia computer-based training (CBT), including eLearning, knowledge management infrastructure, and the support components made available through the Internet and communication facilities, as shown in Figure 4.

CONCLUSIONS

This chapter described design approaches to assist the knowledge worker of today by leveraging technology to support learning and performance. The basic premise of the approach is incorporating new techniques to deliver just-in-time learning into an EPSS design. Design for this purpose needs sound judgment and decision about pedagogy, which is often the main cause of failure, not the technology. It should be realized that merely hosting Web pages with all the information about the subject is not what eLearning is about. Better learning will not occur if only a conversion of media is effected—from paper to digital.

With sound design, the potentials of interactive multimedia technologies for learning and performing are many. Technology is available now to make learning interesting and activity oriented. It is possible to create low-cost alternatives for learning with active experimentation through virtual laboratories, where learning occurs through practicing and visualizing the concepts. Most importantly, it is possible to make these benefits available in a consistent way to a wider cross-section of people covering a large geographical area.

Gary S. Becker, Nobel laureate and professor of economics and sociology at the University of Chicago, argues the following (Ruttenbur, Spickler, & Lurie, 2000):

The beginning of this century should be called "The Age of Human Capital." This is because the success of individuals and economies succeed will be determined mainly by how effective they are at investing in and commanding the growing stock of knowledge. In the new economy, human capital is the key advantage. (p. 12)

In the knowledge-based economy, organizations as well as individuals need to focus on protecting their biggest asset: their knowledge capital. Therefore, the leaders of companies competing in the knowledge economy have to recognize the importance of efficient knowledge management as well as the importance of developing and enhancing their intellectual capital leveraging technology.

The increasing economic importance of knowledge is blurring the boundaries for work arrangements and the links between education, work, and learning. In this regard, the electronic performance support approach provides a holistic framework for workplace design and redesign.

Of course, the human mind is not going to be replaced by a machine, at least not in the foreseeable future. There is little doubt that teachers cannot be replaced with technology. However, technology can be harnessed as a tool to support the new paradigm. We can derive much gain by adopting information and communication technologies appropriately, especially as we look for new solutions to provide the knowledge worker with immediate learning opportunities.

Chapter 5.7
Planning for Multimedia Learning

Patrick J. Fahy
Athabasca University, Canada

ABSTRACT

Multimedia tools, applied with awareness of the realities of organizational culture, structures and finances, have been shown to enhance the performance of learning systems. If some predictable pitfalls are avoided, and proven pedagogical design principles and appropriate vehicles (including the Internet) are used effectively, multimedia can permit greater individualization, in turn fostering improved learning, learner satisfaction, and completion rates.

INTRODUCTION

Effective uses of multimedia in open and distance learning (ODL) depend upon various factors, some intrinsic to the media themselves, and others related to the differing pedagogic tasks and organizational environments into which these tools are introduced. For those planning use of multimedia, it may be valuable to consider the likely impacts of these tools on teaching and learning practices and outcomes, and on organizational structures and processes, as they are likely to be different in scope and magnitude from those of traditional instructional innovations.

This chapter discusses some of the characteristics of multimedia in relation to basic pedagogic tasks and organizational realities. The goal is to alert new users to issues that often arise in multimedia implementations and to assist experienced users in assessing their strategies, by outlining some fundamental considerations commonly affecting implementation of multimedia. Both new and experienced technology users will hopefully find the discussion useful for reflecting on options, and anticipating potential pedagogic and administrative challenges, as they move from simpler to more complex combinations of media for teaching.

The chapter begins with a discussion of the term *multimedia*, including a review of some of the characteristics (including common pedagogic benefits and potential issues) of specific media. Based on this analysis, some of the conditions under which multimedia might readily support

learning tasks are explored. Finally, the impact of multimedia as an innovation on aspects of organizational culture (including structure and finances) are addressed.

Defining Multimedia

While the term "multimedia" has not always been associated with computers (Roblyer & Schwier, 2003, p. 157), there is no doubt that it is the merging of increasingly powerful computer-based authoring tools with Internet connectivity that is responsible for the growing interest in and use of multimedia instruction, in both distance and face-to-face environments. This trend is encouraged by growing evidence that well-designed online delivery, regardless of the media used, can improve retention, expand the scope and resources available in learning situations, and increase the motivation of users (Fischer, 1997; Bruce & Levin, 1997; Mayer, 2001). For these reasons, the term "multimedia" is now firmly associated with computer-based delivery, usually over the Internet and accompanied and supported by interaction provided via some form of computer-mediated communication (CMC).

Definitions of multimedia vary in particulars but tend to agree in substance. Mayer (2001, p. 1) defined multimedia learning simply as "presentation of material using both words and pictures." Roblyer and Schwier (2003) observed that definition is problematic, because it is increasingly difficult to distinguish multimedia from other tools with which it seems to be converging. They also note that multimedia have sometimes been defined simplistically by the storage devices they employ, e.g., CD-ROM, videodisc, DVD, etc., a practice they regard as clearly inadequate. Roblyer and Schwier offered this definition of multimedia: "A computer system or computer system product that incorporates text, sound, pictures/graphics, and/or audio" (p. 329). They added that the multimedia implies the purpose of "communicating information" (p. 157).

In keeping with the above, in this chapter, the term "multimedia" refers to the provision of various audio and video elements in teaching and training materials. Usually, the delivery of the media is by computer, and increasingly, it involves the Internet in some way, but the storage and delivery devices, as noted above, are secondary to the forms of the stimuli that reach the user. The definition assumes that media are used, but it does not address such design issues as choice of specific media for differing pedagogic purposes and levels of user control.

Basic to considering how specific media contribute to the effectiveness or ineffectiveness of multimedia is a brief discussion of the available research on technology in learning. Multimedia technologies invariably consist of media with effects on learning that have been studied before, making this knowledge pertinent and applicable here (Saettler, 1990).

MEDIA AND LEARNING

Specific Media Characteristics

For some time, media have been used with more traditional delivery methods (lectures, tutorials) to support essential teaching objectives, such as the following (Wright, 1998):

- Clarifying and illustrating complex subjects
- Adapting to individual learning styles
- Improving retention and aiding recall
- Reaching nonverbal learners

Debates have occurred over the precise role of media in learning. The fundamental disagreement between Clark (1983, 1994) and Kozma (1994) about media and learning is familiar historically and need not be repeated here. It seems clear that Mayer's (2001) views of multimedia (discussed later) clearly support one point made in that debate, that of the "interdependence" of presentation

media and delivery methods in certain circumstances, especially in collaborative situations, and where higher-order learning is an objective (Crooks & Kirkwood, 1988; Juler, 1990; Koumi, 1994). As Berge (1995, p. 23) concluded, and as has been documented by Mayer (2001), "Some media channels promote particular interactions, and other channels can hinder that same type of interaction."

While the potential for successful high-level learning outcomes is present in media use, a persistent problem in multimedia applications has been failure to achieve more than low-level learning outcomes (Bloom, Englehart, Furst, Hill, & Krathwohl, 1956). Helm and McClements (1996) commented critically, "Interactivity in the context of multimedia often refers to the learners' ability to follow hypertext links or stop and start video clips…. Much of what passes for interactivity should really be called feedback" (p. 135). These are serious criticisms, justifying Mayer's (2001) advice, "Instead of asking which medium makes the best deliveries, we might ask which instructional techniques help guide the learner's cognitive processing of the presented material" (p. 71).

The varying characteristics of different presentation media and modes, and their implications for learning, have direct implications for the design of multimedia strategies and materials. *Sound* can supplement visual information and can be used to attract attention, arouse and hold interest, provide cues and feedback, aid memory, and provide some types of subject matter (heart or machinery sounds, voice clips). *Music* can be used to augment feedback, grab attention or alert users, and support the mood of a presentation. *Synthetic speech*, while useful for handicapped users, is less effective if too mechanical sounding. Szabo (1998) concluded that achievement gains due to audio are "weak or non-existent." He added that where benefits are seen, they tend to accrue to the more highly verbal learners. Problems with development costs and bandwidth for delivery of audio can also be significant (Wright, 1998; Szabo, 1998).

Graphics and color can be used for various purposes, from simple decoration to higher-level interpretation and transformation (helping the observer to form valid mental images) (Levin, Anglin, & Carney, 1987). Research has shown that realism and detail are not critical in graphics and may, in fact, extend learning time for some users; relevance is more important than detail (Szabo, 1998). Color may also distract some learners, unless it is highly relevant to instruction. A significant proportion of individuals (especially men) have some degree of color-blindness, suggesting that color should be placed under the control of the user where possible. The best contrasts are achieved with blue, black, or red on white or white, yellow, or green on black.

Animation can sometimes shorten learning times by illustrating changes in the operation or state of things; showing dangerous, rapid, or rare events; or explaining abstract concepts. For some, animation increases interest and holds attention better than text or audio, and the resulting learning seems to be retained (Szabo, 1998). Overall, however, research indicates that well-designed and imaginative verbal presentations may be capable of producing similar outcomes (Rieber & Boyce, 1990), leading to the conclusion that animation may not possess many unique instructional capabilities.

Video (motion or sequences of still graphics) can be used to show action and processes and to illustrate events that users cannot see directly or clearly in real time. Video, when used skillfully and artistically, can also emotionally move observers and can produce impacts affecting attitudes similar to in-person observation of real events.

Hypermedia is the linking of multimedia documents, while *hypertext* is the linking of words or phrases to other words or phrases in the same or another document (Maier, Barnett, Warren, & Brunner, 1996, p. 85). Hypertext and hypermedia may be difficult to distinguish and

increasingly difficult to separate from other applications of multimedia (Roblyer & Schwier, 2003). When paired with plain text, hypertext has been shown to be a cost-effective way to extend text's information-conveying capabilities, especially for more capable learners. Szabo (1998) suggested that hypertext should be used more to provide access to information than for actual teaching, in recognition of the need for hypertext materials to be placed in context for maximum impact (especially for less experienced or less capable learners).

Hypermedia is a particularly promising form of multimedia materials designed for ODL (Maier, Barnett, Warren, & Brunner, 1996, p. 85; Roblyer & Schwier, 2003). With advances in hardware, software, and human–computer interfaces, it is now technically feasible to use hypermedia systems routinely in online teaching. Dozens of hypertext and hypermedia systems exist, with most offering three basic advantages:

- Huge amounts of information from various media can be stored in a compact, conveniently accessible form, and can easily be included in learning materials.
- Hypermedia potentially permit more learner control (users can choose whether or when to follow the available links).
- Hypermedia can provide teachers and learners with new ways of interacting, rewarding learners who developed independent study skills and permitting teachers to be creative in how they interact with learners (Marchionini, 1988, p. 3).

There are potential problems, too, in learning with hypermedia, related to the volume and structure of all information found on the Web. The vast amounts of information available can overwhelm the learner, especially if structure is inadequate or procedures such as searches are not skillfully refined, allowing learners to "wander off" and become engrossed in appealing but irrelevant side topics. Learners who do not have independent study skills may not be able to manage the complexity of hypermedia. This problem may not be immediately evident, however, because they *appear* to be engaged and on task, sometimes deeply so.

Other potential problems in teaching with hypermedia include some unique to this medium and others common to all learning situations that require specific skills or make assumptions about learner attributes and characteristics:

- Hypermedia require basic literacy skills. While this may change as increasing bandwidth makes audio and video available, presently, the Internet and its multimedia products rely heavily on text.
- A related problem is that interacting with hypermedia and multimedia requires keyboard and mouse skills, as well as understanding and manipulating function keys. The computer illiterate, the unskilled, or the physically handicapped may be affected.
- More broadly, accessing hypermedia and multimedia requires computer use, including sitting in front of the machine and making sense of its cues and displays. Those with vision, concentration, coordination, or mobility problems, or those distracted or confused by the intense stimulation of colors, animation, sound, etc., may be penalized.

The above specific features of media have been shown to affect their usefulness for teaching and learning. In addition to the limitations of media, a key point here is the importance of historical media research to the present discussion: multimedia are *media*, and the view taken in this chapter is that knowledge previously gained about their impact on learning is still highly applicable.

Media Characteristics, Teaching Conditions, and Learning Outcomes

When media are used together, their effects can interact, sometimes unpredictably. With media, "more is not necessarily better."

There is as yet little thorough research on multimedia technologies to inform design and implementation decisions; use of previous research may help guide present practice. What follows is a discussion of some key didactic purposes to which media may apply, followed by some remarks about the Internet as a base for multimedia delivery.

Evaluations have shown that a fundamental benefit to students from the best uses of technology in teaching is a more systematic approach to the individualization and customization of instruction (Massy & Zemsky, 1999). Properly designed, a technology-based learning environment provides students with more options than are typically available in traditional learning situations, in content, pace, preparation, and review of prerequisites, and for activities such as collaboration, consultation, and testing/evaluation. These are objectives that have long been recognized as pedagogically essential (Zimmerman, 1972; Mezirow & Irish, 1974; Kemp, 1977; Dede, 1996; Roblyer, Edwards, & Havriluk, 1997). Among the benefits of technology delivery are the potential for less required training time; greater mastery and better transfer of skills; more consistency in delivery of content (a particularly important outcome of skill training); and greater student persistence, completion, satisfaction, collaboration, and self-direction (Grow, 1991; Moore, 1993). In some situations, experience has shown that highly self-directed students may be able to undertake and complete advanced studies with little or no direct assistance or intervention from the institution, increasing efficiency through the "unbundling" of learning from direct teaching (Massy & Zemsky, 1999, pp. 2–3). In the best examples, technologies increase learning, enhance learner satisfaction, stabilize costs, and raise the visibility and appeal of (and potential revenues from) existing programs (Oberlin, 1996).

While positive effects are possible in teaching with media, they are not automatic. Internal consistency of objectives is critical: multimedia technologies must be congruent with the organization's learning model and actual teaching practices, as well as with students' expectations and capabilities for autonomy and self-direction (Grow, 1991). If tools are chosen for their technological capabilities alone, there is a risk of failing to fit with the organizational environment (Helm & McClements, 1996; Mayer, 2001; Welsch, 2002), resulting in potentially disastrous technology implementation "mistakes" (Quinn & Baily, 1994).

Despite differing characteristics, useful online training technologies have in common the effect of bringing the student into timely and productive contact with the tutor, the content, and peers, thereby reducing the "transactional distance" in distance learning, the communications gap or psychological distance between geographically separated participants (Moore, 1989; Chen & Willits, 1998). The differences in how various media accomplish their effects are important to their potential usefulness. Figure 1, for example, compares instruction delivered by human and technological means (Fischer, 1997).

Illustrated in Figure 1 are some of the trade-offs inherent in the decision to use teaching media, as opposed to traditional forms of delivery alone. If a critical value for a program is met by tutor-based delivery, and resources are plentiful, it may be chosen without regard for cost. Where economy is important, however, the "best" delivery solution may not be affordable; a less costly but still adequate solution may have to be chosen. (This was the purpose of Bloom's [1984] "two-sigma" challenge, to find a teaching medium as effective as one-on-one tutoring. The search, of course, continues with multimedia.) Analysis such as the above may assist in identifying the trade-offs involved in the choice of one medium or technology over another and may suggest compensating strategies to improve the effectiveness of whatever tool is chosen (Wolfe, 1990).

Besides cost and accessibility (Bates, 1995), another issue in selecting media is the type of

Figure 1: Comparison of characteristics of human- and technology-based instruction

Training element	Human-delivered training	Technology-based training
Planning and preparation	Able to design training to correspond to the training plan; able to monitor consistency	Must be systematically designed to conform to the training plan
Expertise	Presenters hired from industry usually represent the most current knowledge and highest expertise	Must be designed to conform to industry standards; currency with standards must be maintained
Interactivity	Instructors tend to train the group, ignoring individual needs	Able to focus on individual needs in content, pacing, review, remediation, etc.
Learning retention	Retention rates vary	Can be up to 50% higher than instructor-led group training
Consistency	Instructors tend to adapt to the audience, sacrificing consistency	Rigorously maintains standards but may also be designed to adapt to learner's performance or preferences
Feedback, performance tracking	Human instructors especially good at constant, ongoing evaluation, response to trainee performance	Better at keeping records and generating reports, but designing cybernetic systems to adapt instruction based on feedback is costly, complex

experience or learning outcomes intended by the training (DeSanctis & Gallupe, 1987). Picard (1999), for instance, sees the key contribution of media as their ability to promote *relationship building*, and not merely *information exchange*, in work or learning.

From Figure 2, we see the following:

- When relationship-building and information exchange needs are both low, audio media alone may suffice.
- When both relationship-building and information-exchange needs are high, audio, video, and information exchange (including text) should all be present.
- Relationship-building is enhanced by combining audioconferencing and video together with data, especially text. (Text alone has substantial relationship-building capabilities, as anyone who has ever had a pen pal, or exchanged love letters, can attest.)

In relation to learning, technologies have potential directly to address common teaching tasks. In Figure 3, the views of several theoreticians regarding tasks or conditions essential to learning are compared. Two points should be noted in this comparison: (a) there is considerable apparent agreement among authorities on elements essential to effective teaching and learning, and (b) there appear to be obvious roles for multimedia in supporting some of these tasks.

A broader point in this discussion is made in Figure 3: technologies have capabilities to assist in specific teaching tasks, if used within their identified limitations as presentation and delivery media. The purpose of research on media is to identify characteristics (capabilities and limitations) that can then be applied in the ID phase, thus avoiding use of the wrong tool for a specific pedagogical purpose. Previous media research can be useful in identifying multimedia implementations able to supply or support the following:

- **Instruction—**CAL (computer-assisted learning), including various types of simulations, can be used, supported by varieties of CMC (e-mail, synchronous and asynchronous IP-audio- and IP-videoconferences, text-chat, file exchanges, and data access).

Figure 2: Relation of data, audio, and video technologies to information exchange and relationship-building outcomes

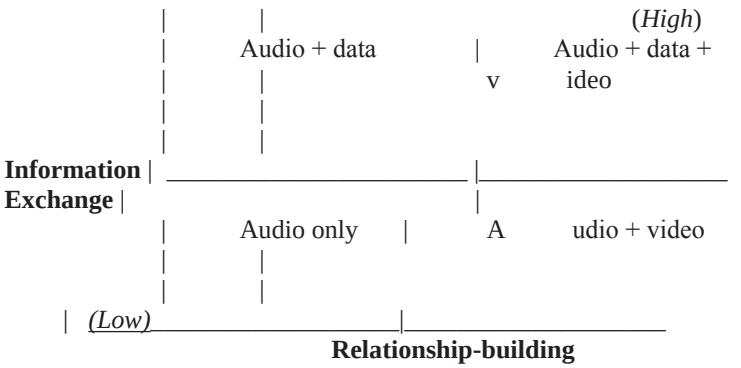

Figure 3: Comparison of models of effective teaching and learning: roles for multimedia

Bloom (1984)	**Chickering & Gamson (1989)**	**Gagne (1985)**	**Joyce & Weil (1980)**	**Moore (in Garrison, 1989)**
Tutorial instruction	Student–faculty interaction	Presenting new material; describing objectives; gaining learner's attention	Presenting stimuli, objectives; sequencing learning tasks	Communicating in an understandable manner
Reinforcement	Student–faculty interaction	Recalling previous learning; enhancing retention and recall	Increasing attention; promoting recall	General support
Corrective feedback	Proper feedback	Providing feedback on performance	Prompting and guiding	Feedback
Cues and explanations	Student–faculty interaction	Learning guidance	Prompting and guiding	Guidance
Student participation	Active learning; student reciprocity and cooperation	Student performance	Evoking performance	Active involvement
Time on task	Time on task; communicating high expectations	Assessing performance		
Assessing and enhancing learner's reading and study skills	Respecting diverse ways of learning			

- **Reinforcement, corrective feedback, and cues and explanations—**CAL and, especially, CML (computer-manager learning) can be useful.
- **Participation, engagement, time-on-task—S**trategies for collaboration and cooperation with peers and authorities include various forms of problem-based learning, using Internet-based communications tools. Motivational advantages are gained from the scope of access and the immediacy of interaction provided by the Web.
- **Assessing and respecting diverse learning styles, preferences—**Though not cited by all the authorities in Figure 3, this may be one of the most powerful arguments for multimedia delivery. (As Fletcher [1992] recognized more than a decade ago, individualization is both "a morale imperative and an economic impossibility"—unless, it is argued here, use is made of well-designed multimedia resources.)

As noted earlier, technologies vary in their immediacy and interpersonal impact. For example, video affects the likelihood and, according to some research, the speed with which relationships will grow in mediated interaction, while simple data exchange may do little to promote relationships in virtual work teams (Walther, 1996; Picard, 1999). The objectives of the instruction should dictate the media to be used and must be grounded in the media's demonstrated capabilities; the choice of media thus both affects and reflects the relative emphasis on different desired learning outcomes.

Multimedia and the Internet

Multimedia are increasingly associated with the Internet, which offers both delivery advantages and challenges to users: advantages arise from the Internet's enormous capacity to link and interconnect, but there are potentially serious problems related to lack of inherent structure and tutor control (Thaler, 1999; Stafford, 1999; Campbell, 1999). Advantages of the Internet for teaching, under ideal conditions, include the following (Heinich, Molenda, Russell, & Smaldino, 1996, p. 263):

- ***Engrossing:*** The opportunity for deep involvement, capturing and holding learner interest.
- ***Multisensory:*** The incorporation of sounds and images along with text (but see Mayer's [2001] *multimedia principles,* below, regarding the limits of sensory channels).
- ***Connections:*** Learners can connect ideas from different media sources, for example, connecting the sound of a musical instrument with its illustration.
- ***Individualized:*** Web structure allows users to navigate through the information according to their interests and to build their own unique mental structures based on exploration.
- ***Collaborative creation:*** Software allows teachers and learners to create their own hypermedia materials; project-based learning provides opportunities for authentic collaboration.

Some of the more common problems with the Internet for teaching, and as a platform for multimedia delivery, are as follows (Heinich et al., 1996, p. 263):

- ***Getting lost:*** Users can get confused, or "lost in cyberspace."
- ***Lack of structure:*** Those whose learning style requires more structure and guidance may become frustrated. Some less-experienced or less well-disciplined users may also make poor decisions about how much information they need.
- ***Noninteractive:*** Programs may simply be one-way presentations of information with no specific opportunities for interaction or practice with feedback. A further problem is that, due to poor design, what may be intended as *interaction* is sometimes more accurately called *feedback* (Helm & McClements, 1996).
- ***Time-consuming:*** Because they are nonlinear and invite exploration, hypermedia programs tend to require more time for learners to reach prespecified objectives. Because they are more complex than conventional instructional materials, hypermedia systems require more time to master ("Workers find," 2000).
- ***Bandwidth***: This continues to be a critical barrier to Web-based multimedia use for some potential users. While broadband availability is increasing worldwide (*PC Magazine*, 2003), especially outside North America ("Where's the broadband boom?," 2002), online speeds still prevent many users from accessing multimedia efficiently or reliably (Howard, 2001; Miller, 2002).

The above inherent limitations of the Internet as a multimedia delivery tool arise from its very nature. In order for these limitations to change, the Internet would have to become more structured, limiting user choices. This is unlikely, as these changes would make the Web a very different entity from what it is today (Greenaway, 2002).

Planning Issues with Multimedia

Design and Development Principles

The potentials and challenges discussed above underscore the importance of planning and design in the implementation of multimedia. Fortunately, research offers principles that can guide instructional designers and instructors in the development and use of multimedia. Mayer's (2001) work is particularly useful. His examination of the impact of multimedia on learning, based on how the human mind works to process verbal and visual information (p. 4), has produced important insights about media and learning, including the following:

- Words and pictures, although qualitatively different, complement one another and promote learning, *if* learners are successful in mentally integrating visual and verbal representations (p. 5).
- True learning is more a process of knowledge construction than information acquisition (p. 12).
- Deep learning is evidenced by retention *and* transfer (lack of which indicates no learning, or merely superficial rote learning) (pp. 5, 16–17).

In Mayer's model, there are three key assumptions underpinning a cognitive theory of multimedia learning: (a) humans have dual channels for processing input as part of learning, the *visual* and the *auditory*; (b) while the two channels exist in most people, humans are limited in the amount of the information they can process in each channel at one time; and (c) learners must actively process information and experience as part of learning, by a process that includes attending to relevant incoming information, organizing selected information into coherent mental representations and integrating mental representations with other knowledge (p. 44).

Mayer (2001, p. 41) concluded that successful learning requires students to perform five actions, with direct implications for the design of effective multimedia instruction:

1. Select relevant words from the presented text or narration.
2. Select relevant images from the presented illustrations.
3. Organize the selected words into a coherent verbal representation.
4. Organize selected images into a coherent visual representation.
5. Integrate the visual and verbal representations with prior knowledge.

Mayer articulated seven principles useful for guiding the design of multimedia instruction. Under these principles, students have been shown to achieve greater retention and transfer (Mayer, 2001, p. 172):

1. **Multimedia principle**: Students learn better from words and pictures than from words alone.
2. **Spatial contiguity principle**: Students learn better when corresponding words and pictures are presented near rather than far from each other on the page or screen.
3. **Temporal contiguity principle**: Students learn better when corresponding words and pictures are presented simultaneously rather than successively.
4. **Coherence principle**: Students learn better when extraneous words, pictures, and sounds are excluded rather than included. ("Extraneous" can refer either to *topical* or

conceptual relevance, with the latter being more important.)

5. **Modality principle**: Students learn better from animation and narration than from animation and on-screen text. (This principle assumes use of a *concise narrated animation*, text that omits unneeded words.) (See p. 135.)
6. **Redundancy principle**: Students learn better from animation and narration than from animation, narration, and on-screen text. (This principle is based on *capacity-limitation hypothesis*, which holds that learners have limited capacity to process material visually and auditorily [p. 152]. Eliminating redundant material results in better learning performance than including it [p. 153]).
7. **Individual differences principle**: A particularly important finding is that design effects are stronger for low-knowledge learners than for high-knowledge learners, and for high-spatial learners than for low-spatial learners (p. 184).

The above are examples of design principles under which learning *may* be enhanced by the use of various display or delivery media. Principles such as these are particularly important, as they are research-based and tested (Mayer, 2001). Any design principles adopted should meet similarly stringent empirical tests.

Multimedia, Productivity and Performance

The previous discussion suggests that multimedia implementation, while potentially valuable to learning, requires strategic planning to exploit pedagogic possibilities and avoid the pitfalls of misapplication. The point has further been stressed that the existing literature on technology-based learning is applicable to multimedia planning, especially the known pedagogic and representational characteristics of individual media identified in actual learning situations. There are nonpedagogic considerations, too, related to organizational impacts and various costs from the use of multimedia.

A realistic decision to incorporate multimedia in ODL should recognize that multimedia, like most technologies, are unlikely initially, or perhaps ever, to save the organization time or money (Quinn & Bailey, 1994; Burge, 2000; Cassidy, 2000). In fact, multimedia may in the short-term increase operational complexity, create "organizational chaos" (Murgatroyd, 1992), and promote time-wasting behaviors by users throughout the organization (Laudon, Traver, & Laudon, 1996; Fernandez, 1997; Evans, 1998; Fahy, 2000; Dalal, 2001). The early effects of multimedia, like other technologies in complex organizations, may well include *lower* organizational productivity (Black & Lynch, 1996).

Another caveat is financial: the economics of technologies generally suggest that the total cost of ownership (TCO) of multimedia technologies will constantly rise (Oberlin, 1996), and that no genuine cost savings may ever actually be achieved by some users (Welsch, 2002). The rationale for adopting multimedia technologies, therefore, is more related to *performance* enhancements, such as greater flexibility, improved learning, and higher satisfaction and completion rates for users, than to cost savings (Oberlin, 1996; Daniel, 1996; Fahy, 1998).

This point is significant, because, historically, technology users have sometimes confused performance and productivity outcomes in technology implementations, underestimating the costs and long-term impacts of technology, while, to the detriment of realistic expectations, overestimating and overselling possible productivity benefits (Dietrich & Johnson, 1967; McIsaac, 1979; Mehlinger, 1996; Strauss, 1997; Lohr, 1997; Wysocki, 1998; Greenaway, 2002; Hartnett, 2002). For the future of multimedia, avoiding these kinds of mistakes is critical: unrealistic expectations produce disappointment, and may result in skepti-

cism among instructors and managers about the value of educational innovation generally, and educational technologies in particular ("Nothing travels through an educational vacuum like a technological bandwagon.")

Organizational Issues in Multimedia Adoption

Realistic expectations of multimedia require compatibility with the adopting organization's culture, structure, and finances (Welsch, 2002).

The culture of any organization includes its various values, beliefs, myths, traditions, and norms, as well as its historic practices and typical ways of doing business (including how it adopts or rejects innovations). Organizational culture may present the most serious challenges to those responsible for the strategic planning (Rogers, 1983; Stringer & Uchenick, 1986), including the problem of distinguishing whether any resistance encountered is due to simple unwillingness or to real inability (Welsch, 2002). (In the latter case, resistance may be rationale and appropriate, a sign that conditions are not right for an innovation to succeed.) The problem is thought to be particularly acute in slow-to-change enterprises such as public education (Senge, 1990).

Another problem for adoption of complex innovations such as multimedia is the attitude in some organizations that training is an optional activity (Gordon, 1997). Ironically, it is technologically illiterate managers and administrators who most often resist training initiatives, both for themselves and their staff, to avoid embarrassment in an area in which they know their expertise is not as great as their subordinates'. The needs analysis stage of planning is the best place to assure that cultural issues like these are recognized and evaluated in advance.

Planning for multimedia implementation need not be timid. The needs assessment should carefully distinguish *climate* from culture and respond accordingly. Climate consists of the commonly held viewpoints and opinions in the organization, directly influenced by widely recognized measures of organizational health and success, such as enrollment or student achievement and performance relative to competitors. Climate is more "constructed" and temporary than culture, based upon elements such as student and staff perceptions of how well the organization is performing its fundamental tasks. By its nature, climate is more manageable than culture. Managers, by their reactions to external developments, can influence how staff members interpret the outside events that may shape climate. Climate is an area in which planning can have an impact, through the efforts of planners to influence the internal recognition and interpretation of outside events.

In addition to culture, structural factors within the organization may also affect multimedia innovations. The presence and adequacy of the required technological infrastructure, including software, hardware, communications, and networking systems, should be assessed. Personnel in the form of knowledgeable management, maintenance, training and support staff, key consultants, and cost-effective contract help are also critical structural elements. If not already provided for, the costs of system upgrades and ongoing maintenance (including initial and recurrent training for staff) should be assessed in a structural review, preceding the introduction of multimedia systems. Ongoing costs should be identified in budget projections.

Finances are a vital part of any multimedia adoption in ODL. Assessing organizational finances also introduces complexity into the planning process, as costs are inherently difficult to predict accurately, sometimes even to identify completely. While precise accuracy in cost analysis may be difficult, potential purchasers of technologies should be aware that, as noted above, the total cost of ownership of multimedia technology will likely be well above the purchase price, exceeding the purchase price by many times (Oberlin, 1996; Black & Lynch, 1996;

Khan & Hirata, 2001; Welsch, 2002). Using a definition of productivity as the ratio of benefits to costs (Massy & Zemsky, 1999), the high cost of a technology may not be disqualifying if the payback is clear. Costs alone do not necessarily change the justification for a technology, but they could constitute a shock to an organization that has not adequately anticipated them.

Part of the rationale for investing in multimedia is the fact that technology provides flexibility: technologies are more scalable than human resources, *if* this aspect is exploited in the organizational vision. In general, scalability means that program growth may be more easily accommodated with technology than without it; costs do not escalate in line with growth as they do where enrollment increases are borne strictly by hiring more instructors and support staff. Multimedia resources may be augmented or trimmed without reference to collective agreements or other commitments. Another difference is that technologies such as multimedia tend to become more efficient the more use is made of them, lowering the break-even point and increasing their efficiency (Matkin, 1997; Harvard Computing Group, 1998; Watkins & Callahan, 1998).

The decision to acquire technology is fundamentally a strategic one, because technologies are means to various ends. Bates (1995) suggested that *accessibility* and *cost* are the two most important discriminators among technologies, and thus the most critical criteria in a technology acquisition process. A decision to "build" or develop a new multimedia technology option should bear in mind that there is now a rapidly increasing amount of available software (Gale, 2001). A careful analysis of needs and a search of available options should be performed, especially before a decision to develop is authorized, as even professional programming projects, in general, often end in failure (Girard, 2003), and instructors who lack special instructional design (ID) training are particularly apt to become bogged down in the development of ultimately mediocre materials (Grabe & Grabe, 1996).

Another factor in assessing the financial viability of various multimedia technologies is the potential target audience in relation to the expected costs of production. Perry (2000) cautioned that custom multimedia training courseware will likely not be cost-effective for fewer than 1,000 users. Bates (1995, 2000) also offered figures and usage considerations that help with the assessment of costs and benefits. Costs and time frames can be formidable: Szabo (1998) reported nearly a fourfold range (40 to 150 hours per hour of instruction) for development of very basic computer-assisted learning (CAL) in health education, and another study reported that a 6 hour module in weather forecasting, involving a production team of instructional designers, meteorologists, hydrologists, graphics artists, media specialists, computer scientists, and SMEs, consumed a year and cost $250,000 (Johnson, 2000).

CONCLUSIONS

Presented in this chapter was a discussion of factors (inherent, pedagogic, and organizational) that may impact planning for multimedia use. The suggestion here is that multimedia are more likely to affect pedagogical performance (how well the program or the organization does its work) than productivity (measured by profitability). In planning for multimedia implementation, it was suggested, performance outcomes should be the focus (improvements in quality of service, as measured by timeliness, accessibility, convenience, and responsiveness of program offerings and supports), rather than "bottom-line" outcomes.

Strategic planning in the form of ID promotes proper uses of multimedia technologies, especially (at the awareness and adoption stages). The best pedagogical arguments for use of multimedia technologies (providing more learner convenience, satisfaction and success) may be compelling enough, but problems in relation to existing organizational culture, structure and finances should

not be overlooked. The adoption process includes distinguishing climate factors from culture (the former being more amenable to influence by effective leaders); considering the needs of affected groups in planning; acknowledging and respecting users' expectations; providing existing managers with training, so they can provide effective leadership; accurately assessing existing and needed technical resources; avoiding overselling potential benefits, thus keeping expectations realistic; and selecting, adapting, or (rarely) building products on the basis of demonstrable advantages, especially accessibility and costs.

Pedagogically, the principal contributions of multimedia technologies in teaching and training are likely to be increased flexibility, resulting in greater learner access and convenience, and more choices to users, including self-pacing, individualization, customization, and learner control. Positive impacts such as these on aspects of the teaching process can be anticipated, but problems should also be expected; media selection usually involves trade-offs, and the losses and gains in the choice of one delivery or presentation medium over another should be acknowledged.

For instructional designers, principles exist to guide development of multimedia. Among the most useful of these are the multimedia principles that address design issues such as contiguity, redundancy, coherence, and choices of delivery modes (Mayer, 2001). Adoption of these principles would, in general, likely result in "lean" multimedia design, with use of audio-textual and visual-pictorial elements based more directly upon empirical evidence about how these actually impact learning, rather than upon their technical features alone. Though perhaps less technologically elegant, such implementations promise to be more pedagogically effective and organizationally compatible.

Chapter 5.8
E-Learning and Multimedia Databases

Theresa M. Vitolo

Gannon University, USA

INTRODUCTION

E-learning covers the variety of teaching and learning approaches, methodologies and technologies supporting synchronous or asynchronous distance education. While distance education is a concept typically used by conventional institutions of education to mean remote access and delivery of instruction, the concept of e-learning broadens the scope to all instances of learning using Web-mediated learning. The scope includes realizing learning organizations (Garvin, 1993), achieving knowledge management (Beccerra-Fernandez; Gonzalez & Sabherwal, 2004; Aussenhofer, 2002) and implementing organizational training.

Individuals continue to learn throughout their lives, particularly as a function of their work and profession. The manner in which they access information and use it often depends upon the available technology, their previously learned response for information acquisition and how their organization facilitates learning and knowledge transfer (Tapscott, 1998; Zemke, Raines & Filipczak, 2000). Hence, e-learning is not simply a consideration for traditional learning institutions, but for any organization.

As such, e-learning not only faces the traditional challenges of teaching to various learning styles while conveying the spectrum of educational objectives, but also faces the extra challenge of using emerging technologies effectively. The three significant emerging technology areas to e-learning are: networking, mobility and multimedia. These technologies can enable a highly interactive delivery of material and communication between instructors and students. Out of the three, however, multimedia technologies relate directly to pedagogical concerns in providing material

tailored to the content domain, to the individual and to the learning objectives (Vitolo, 1993).

Currently, multimedia and e-learning initiatives focus on the presentation of multimedia. The adequate presentation of multimedia is often more an issue of the network being used and its connectivity parameters. Acceptable multimedia presentation depends upon the format of the multimedia and its ability to be quickly transferred (David, 1997). In these circumstances, the availability and appropriateness of the multimedia is assumed to have already been decided as necessary to the instruction.

Not being addressed currently is the storage of multimedia. Multimedia databases should allow for retrieval of components of the integrated and layered elements of the media data stored. In this way, the media would support learning goals. Its retrieval should be conditional upon a context and a content need. Context involves the learning situation – the educational objectives and the learner, combined. Content need includes the particular material to be acquired. Conditional retrieval of multimedia based upon a pedagogical circumstance implies that not all learners or situations need the same media to be delivered, but that a compendium of stored media should be available. In fact, the media alone cannot solely enable learning. Clark (1983) analyzed the effects of learning from different media and observed that significant changes in learning are a function of the media used for the presentation of the material. Significant attention must be given to the content material available for e-learning systems. The material in a certain media format should be included, because it adds or complements the underlying informational intent of the system.

Further, as educational objectives aspire to higher levels of competency such as analysis, synthesis and evaluation, more depth and variety of detail need to be communicated to the student. However, due to the connectivity issues of e-learning, often layers of representation are not available to the learner. For example, during face-to-face communication, student to teacher, the teacher provides the path to the solution and essentially trains the student when teaching analysis skills. However, with e-learning systems, just the end product—the "solution"—of the analysis is provided. When the underlying reasoning layers of the analysis are not available, the overall quality of the instruction suffers (Vitolo, 2003).

Multimedia databases added to an e-learning initiative would provide conditional retrieval and comprehensive storage of multimedia. However, no database management system (DBMS) exists solely for multimedia storage and access (Elmasri & Navathe, 2000). Several current DBMS do provide a data type appropriate for multimedia objects. However, the range of capabilities available for manipulating the stored object is severely limited. A pure multimedia database management system (MDDBMS) is not commercially available, now.

BACKGROUND

Learning, education and teaching are inextricably intertwined, highly complex processes. Each process has been researched as a social phenomenon, cognitive transformation, generational bias and personality expression. While the work on these topics is vast, several aspects are generally accepted as foundation concepts:

- People interact with environments on an individualized basis. Learners have learning styles; teachers have teaching styles; individuals have personality styles.
- Educational efforts seek to find a correspondence between these various styles so that learning can progress effectively.
- Educational efforts can be described via taxonomies—progressions of objectives. The realization of these objectives does not necessarily require any specific learning or

teaching modality. The communication of the content of the objective may be better suited to one modality (visual, auditory or tactile) than another.
- Learning can continue throughout an individual's life.
- Technology can facilitate educational efforts by providing various formatted and comprehensive content for interactive and self-regulated learning. Multimedia technology provides an excellent opportunity for packaging content into a variety of modalities.

With respect to styles, Coates (2002) provides a condensation of the various style-based perspectives of learning. While much of these style-based analyses of behavior stem from the initial work of Carl Jung (1923), the facets of the styles are continually being researched. Learning is mediated by a variety of factors—some (such as modality of instruction) that can be manipulated successfully within an educational effort, some (such as generational cohort biases) that are out of the control of instructional design.

With respect to educational structures, educational researchers have developed taxonomies to explain educational objectives. (See Anderson, Krathwohl, Airasian, Cruikshank, Mayer, Pintrich, Raths & Wittrock, (2001) and Bloom (1984, 1956) for classic coverage of these taxonomies.) Essentially, educational efforts advance instruction in levels of difficulty and performance so that the breadth and depth of the knowledge of a field can be communicated.

As a foundation concept to using multimedia for e-learning, the media requires appropriate processing for adequate capture, production and distribution. For example, video may be shot using either an analog or digital camera. Before the source video can be edited using computer software, it must be instantly accessible from a hard disk and not the original videotape. The source video is imported into the computer by a process called video capture. Captured video is huge; 10 seconds of raw, uncompressed NTSC video (the standard for television video) use as much as 300 megabytes (MB) of storage space.

For video to be played in a Web browser or distributed on CD-ROM, the file size must be reduced significantly. This file size reduction, or compression, is achieved using codecs – compression/ decompression approaches. Source video captured from a digital camcorder will already have been digitized and saved in a digital file format inside the camera. Digitizing a video sequence results in extremely high data rates. For example, an image with a resolution of 720x576 pixels and a color depth of 16 bits produces a data stream of 1.35 MB per individual frame. At the rate of 25 frames per second required to render smooth video scenes, a gigantic data volume of 3,375 MB/second results. This volume is far too great for the average hard disk to handle; a CD-ROM would only have enough space for about 16 seconds (Adobe Press, 2003; Bolante, 2004).

Next, the capture process involves transferring the digitized video file to a computer hard disk. Once captured, the multimedia requires further considerations for production and dissemination considerations. The analog or digital source video is captured using video editing software and saved into an appropriate video format. These video formatted files are also large; 60 minutes of video can consume 12 GB of disk space. The media file is manipulated within software via timing option, making it ready for rendering and production. After rendering, the video file is processed further depending upon its desired distribution modality:

- Exported back to video tape (analog or digital)
- Compressed further for distribution on CD-ROM or DVD
- Compressed further for distribution across the Internet

The final presentation also has options. Progressive encoding refers to where the entire video must be downloaded before any viewing occurs, regardless of its format. This case occurs with any of the formats considered so far. Alternatively, Internet streaming enables the viewer to watch sections of video without downloading the entire file. Here, the video starts after just a few seconds. The quality of streaming formats is significantly lower than progressive formats due to the compression being used (Menin, 2002).

Finally, appropriate display of the material for effective consumption is improved with interactive multimedia. However, interaction with a media file—the goal of interactive multimedia—is restricted; navigation is possible using pause, forward and reverse controls provided by the player installed on the client computer. To create interactive media for the Web, CDs, kiosks, presentations and corporate intranets, a multimedia authoring program is used. These programs enable the combination of text, graphics, sound, video or vector graphics in any sequence. To add more interactive features, powerful scripting languages are also provided (Gross, 2003).

Hence, the situation for e-learning is bound in several ways by the available multimedia technology. First, the production and distribution of multimedia is not a trivial undertaking, requiring specialized skills and technologies. Second, the viewing of the multimedia requires the client machine and user to have appropriate technology. Third, the goals of the e-learning effort must be in balance with the available and expected technology. Fourth, the multimedia technology itself is providing limited options for interactive manipulations. After these steps, the media as a data-rich structure can be stored in multimedia databases.

LIMITED STATE OF E-LEARNING AND MULTIMEDIA DATABASE SYSTEMS

The requirements for the next era of e-learning applications using multimedia databases are:

1. Repository systems offering storage and access capabilities of media
2. Indexable storage structure for media files as contiguous structures composed of identifiable and searchable elements
3. Tier-architecture deployment providing multiple application access

With respect to point 1, DBMS implementations are commercially available that can reference media files in a variety of formats. The media file is handled as a complete unit through a large object (LOB) data type. For instance, Oracle introduced a set of LOB data types with Oracle 8 to facilitate the storage of large-scale digitized structures and references to them. The media itself is stored in one of two ways: as a LOB (usually BLOB) type within the database, or in an external file and pointed to by a BFILE type within the database.

Oracle has continued to advance the integration of these LOB data types through its database versions and the various tools it offers. Oracle's *inter*Media management system and Oracle 10g database support various media specific object types, recognize and record facets of the media's attributes in metadata structures, and provide support to multimedia needs for various applications and enterprise-wide delivery. The *inter*Media objects of ORDAudio, ORDImage, ORDVideo and ORDDoc provide attributes and access capabilities recognized by the end-user application (Oracle, 2003, 1999).

With respect to point 2, however, media data are not handled as an indexed structure. Thus, access to incremental slices or partitions of the media is not a current capability. Access to the

attributes of the entire media as a unit has been improved, but more is desired for e-learning. A beginning point would be a query standard for multimedia and its internal elements. Oracle 10g does support a portion of the first edition of the ISO/IEC 13249-5:2001SQL/MM Part 5: Still Image Standard. The standards community and commercial vendors continue to address the query needs of multimedia and applications.

With respect to point 3, multimedia applications may not have any database component. The media is handled as a data item manipulated by the script of the application (David, 1997). This situation mimics the file-processing era; namely, that the data manipulated by one file for its application's needs may not lend itself to manipulation for another, separate application's needs.

A more desirable architecture for multimedia delivery is a three-tier one. The advantages of a multi-tier architecture are:

- Separation of the user interface logic and business logic
- Low bandwidth network requirements
- Business logic resides on a small number (possibly only one) of the middle machines

Together, these aspects promote greater accessibility across various applications and ease of maintenance through hardware and software upgrades.

E-learning has benefited from the enhanced broadband and accessibility of the public infrastructure. As such, the popularity and market presence of the initiatives have grown. The initiatives offer delivery convenience, communication channels and content volume. These three factors make e-learning a highly attractive possibility for a variety of learning circumstances.

In many respects, however, current e-learning initiatives are similar to page-turning, computer-assisted instruction packages of earlier computer-based learning efforts. That is, the initiatives lack pedagogical development and refinements, tailoring the instruction with respect to a student model and to the complexities of higher-level educational objectives.

The higher levels of educational objectives need to communicate greater complexity in the detail, explanation and incremental refinements of the content. If only the final result of the analysis, synthesis or evaluation is the goal of the instruction, then current multimedia efforts would be fine. However, higher-level educational objectives require more layers and connections to be communicated—more complex structures need to be communicated in order to teach more complex concepts. Further, this type of refinement of complex structures through incremental layers of development, feedback, and progress is desirable for effective education and for effective handling of learning styles given a learning situation. To achieve mediated learning episodes with this finesse, the next generation of multimedia applications and deployment utilities are necessary.

FUTURE TRENDS & CHALLENGES

Multimedia capabilities will continue to improve, becoming more economical and more usable. In time, the authoring, production and distribution of multimedia will become as easy as word processing. As with many information systems efforts, the challenge resides with understanding the infrastructure commitment to deploy such efforts in terms of hardware, skills and procedures. Successful efforts require high-capacity, secure servers and connections. Individuals need to understand the nature of multimedia to manipulate it successfully within the software. Finally, well-defined procedures for the distribution and maintenance of the multimedia over a desired architecture must accompany the effort and must be handled by systems staff cognizant of the desired performance levels.

The future of multimedia databases shares this same positive outlook. The capabilities sought in various data-typing of media, querying of media segments and indexed aspects need continued addressing.

For e-learning, the challenges parallel those of multimedia. E-learning efforts need to understand how the infrastructure can limit the instructional goals. The skill level for development efforts requires technical competence and instructional design principles. When future e-learning efforts include multimedia databases, then the required technical skills will be further specialized. E-learning efforts will require teams of highly specialized individuals, bridging the different technical needs for pedagogy, multimedia and multimedia databases.

The final future challenge to be addressed is one shared with many Web-based developments—intellectual property rights. Intellectual property is a sufficiently difficult concept currently when multimedia is part of a single application. Once the multimedia is part of applications connected through a database, then the intellectual property rights of the database and its development must be considered also.

CONCLUSION

E-learning continues the efforts of computer-mediated instruction. The depth and interactivity potential of multimedia components is a highly attractive factor to add to instruction. Multimedia offers the capability to construct interactions tailored to the learning needs of a specific student, within a specific learning context, being taught a specific content domain.

Multimedia technology has matured significantly as its complementary technologies of network capacities and deployment hardware have advanced. However, for the next generation of multimedia and e-learning to progress, multimedia databases should be used. The database configuration would increase the potential use of the multimedia across multiple application instances, the multimedia could be queried for access and, ultimately, the elements composing the multimedia could be accessed as opposed to accessing the entire multimedia file—the current option for multimedia access.

Multimedia databases not only would enhance the technical delivery of e-learning efforts, but also would enhance the pedagogical aims of e-learning efforts. Instruction of the higher-order educational objectives requires layers of a representation to be presented. Multimedia databases could store media in its elemental segments so that selective delivery of pieces of the media could be offered for instruction—not the media file in its entirety, leaving the parsing of the relevancy of the media to the discretion of the student.

While multimedia databases would increase the flexibility, access and reuse of the media, other challenges arise. Multimedia databases are complex technologies requiring more specialized skills beyond simply building and deploying multimedia. Adequately supporting multimedia databases requires continued, expensive investments in infrastructure to support the deployment of the databases and e-learning efforts. Further, not all of the required features of true multimedia databases have been developed to date, but are part of the current efforts of database developers and of standards communities. Finally, intellectual property issues are a challenge of applications using multimedia databases. As in most development aspects, the intellectual property issues will be as difficult to resolve as the technology was to develop.

KEY TERMS

Bit Depth: The number of bits used for color resolution when viewing a movie.

Codec: Compression and decompression algorithms provided by either a software application or a hardware device.

Database Management System (DBMS): Collection of software components to store data, access the data, define data elements, store data element definitions, build data storage structures, query the data, backup and secure the data, and provide reports of the data.

E-Learning: All teaching and learning processes and functions from course authoring, course management, examinations, content delivery, feedback and course administration developed, delivered and monitored through synchronous or asynchronous communication.

Encoding: The process of using codecs to convert video files to different distribution file formats. The codecs used for encoding files for CD-ROM and DVD are MPEG-1 and MPEG-2, respectively.

Frame Rate: The number of frames projected per second.

Frame size: The height and width of the video window according to the number of pixels.

Internet Streaming: Video format that intermittently downloads sections of a media file to a client.

Knowledge Management: The set of initiatives to identifying, retrieving, organizing, disseminating and leveraging intellectual capital—usually as an enterprise-wide effort.

Learning Styles: A cognitive perspective of individualized preferences for modalities when learning; includes a learner's manner of responding to and using stimuli while learning.

Multimedia Database: Database storage and retrieval capabilities developed with respect to multimedia requirements for high-quality, rapid, queried usage by applications.

Progressive Encoding: Video format that downloads the entire media file to the client before any displaying occurs.

INTRODUCTION

The digitization of educational content is radically transforming the learning environment of the student. A single lecture, as well as supporting reference material, textbook chapters, simulations, and threaded chat system archives, may be captured on one hour of video, a set of 20 or more slides, and ancillary text resources. A single course may contain 25 such lectures and a single department may have 30 distinct courses that have been digitized in a single year. If, while taking one course, a student wants to find a relevant definition, example, discussion, or illustration of a concept, then the student would potentially need to search as much as 750 hours of video, 15,000 slides, and a huge volume of text in order to find the desired information. Thus the online student is overwhelmed by a flood of multimedia data which inhibits the development of insight.

Insight is a key ingredient of education and is most often achieved by the manipulation of information through the discovery of new relationships, identification of hidden structures, or the construction of domain models. The methodology of instructional design may be used to anticipate the needs of the student in the controlled environment of a classroom with novice learners, but it is inadequate for the needs of a heterogeneous population of online learners. Intelligent tutoring systems provide an additional degree of flexibility for the independent learner, but are

difficult to produce and maintain. The advanced learner needs powerful search and organizational tools to support self-guided learning. In all three cases there is a need for content-based retrieval of multimedia resources ranging from simple indexing and navigation of lectures to ontology-based mining of information nuggets from large repositories of heterogeneous content.

The needs of the independent learner are particularly demanding due to the requirements for real-time, context-dependant, and precise retrieval of unstructured and incomplete information distributed across multiple media sources. Due to the large size of the corpus and the highly focused nature of the target information, the systematic labeling (either manually or automatically) of the media is not feasible. Instead, we propose a system for *media hot spotting.*

Media hot spotting is the process of finding *hot spots* within the text, audio, video, and other media content. A hot spot may be a distribution of key terms in a text document; a matching distribution of terms in the speech track of a lecture video; or a sequence of writing, emphasis, and gesture events in the video stream of a lecture, where an event is a spatial or temporal set of interrelated features. Individually, each piece of information does not convey sufficient semantic information to identify the informational content of the media. In combination, they provide significant evidence, for instance, that a Definition event has occurred in the media and that a particular term has most likely been defined within the context of this event. Thus, given a model for how information co-occurs across different media objects, hot spotting enables the rapid retrieval of candidate media content for further analysis and reference.

Content-based solutions are available for domains like sports and news, but have not yet been systematically explored for educational videos (Idris & Panchanathan, 1997; Mittal & Cheong, 2003; Woudstra et al., 1998). This chapter describes a new method of content-based retrieval for e-learning videos using camera motion cues, audio features, slide layout, and associated decision rules. Using this technique, we are able to separate the lecture videos into several component states and personalize the video from these states. For our experiments, we used 26 lecture videos from the Singapore-MIT Alliance, along with the associated PowerPoint slides.

This chapter is organized as follows. The next section presents a discussion of an existing distance learning program (SMA) and other related work. Then an overview of our approach is presented, followed by the section titled "Multimedia Indexing Features," where we show the framework for modeling multimedia information and present a list of the most useful features used in the video segmentation task. The section titled "Indexing of Lectures" elaborates upon the mapping of low-level features to lecture semantics. Finally, we discuss the experimental results and significance of this approach.

DISTANCE LEARNING PARADIGM

Singapore: MIT Alliance Educational Setup

The work presented here relates to the materials used in the Singapore-MIT Alliance (SMA)[1] development program. SMA is an innovative engineering education and research collaboration among the National University of Singapore (NUS), Nanyang Technological University (NTU), and the Massachusetts Institute of Technology (MIT). SMA classes are held in specially equipped classrooms at the Singaporean institutes and at MIT using live video transmission over the Internet. The synchronous transmission allows participants at both locations to see each other and speak normally. However, because of the 12-hour time zone difference, SMA has made a great effort to find and develop tools to enhance asynchronous learning.

SMA lectures are given daily, and it is expensive to process, index, and label them through manual methods. Immediate availability of the lectures is also important because the courses are fast paced and build sequentially upon earlier lectures. Techniques for the efficient indexing and retrieval of lecture videos are required in order to cope with the volume of lecture video data produced by the SMA program and other media-intensive programs.

SMA is just one example of how the application of information technology to digital media is rapidly enhancing the field of distance education. The effective use of information technology enables institutions to go beyond the classroom to create personalized, lifelong learning for the student. This results in a repository of potential learning experiences that is available not only for the student, but also available for incremental refinement and elaboration by the lecturer.

Related Work

Using video for educational purposes is a topic that has been addressed at least since the 1970s (Chambers & Specher, 1980; Michalopoulos, 1976). Recently the focus of the research has been on the maximum utilization of educational video data which has accumulated over a period of time. Ip and Chan (1998) use the lecture notes along with Optical Character Recognition (OCR) techniques to synchronize the video with the text. A hierarchical index is formed by analyzing the original lecture text to extract different levels of headings. An underlying assumption is made that the slides are organized as a hierarchy of topics, which is not always the case. Many slides may have titles which are in no way related to the previous slide.

Bibiloni and Galli (1996) proposed a system using a human intermediary (the teacher) as an interpreter to manually index the video. Although this system indexes the video, it is highly dependent upon the vocabulary used by the teacher, which may differ from person to person. Moreover, even the same person may have a different interpretation of the same image or video at different times, as pointed out by Ip and Chan (1998).

Hwang, Youn, Deshpande, and Sun (1997) propose a hypervideo editor tool to allow the instructor to mark various portions of the class video and create the corresponding hyperlinks and multimedia features to facilitate the students' access to these prerecorded sequences through a Web browser. This scheme also requires a human intermediary and thus is not generalized.

The recently developed COVA system (Cha & Chung, 2001) offers browsing and querying in a lecture database; however, it constructs the lecture index using a digital textbook and neglects other sources of information such as audio or PowerPoint slides. A similar work (Mittal, Dixit, Maheshwari, & Sung, 2003) concentrated on deriving semantic relationships between concepts and answering queries solely based on PowerPoint slides. Thus, it can be concluded that the integration of the information present in various e-learning materials has not been systematically explored.

STATE MODEL FOR LECTURES AND OVERVIEW OF OUR APPROACH

The integration of information contained in e-learning materials depends upon the creation of a unifying index that can be applied across information sources. In content-based retrieval systems, it is often convenient to create a *state model* in which nodes represent semantically meaningful states and the links between nodes represent the transition probabilities between states. Thus, the methodology for constructing an educational video information system begins with the creation of a state model for the lecture, where the states are based on the pedagogical style of teaching. For the purpose of illustrating the concept, let us consider computer science courses, especially

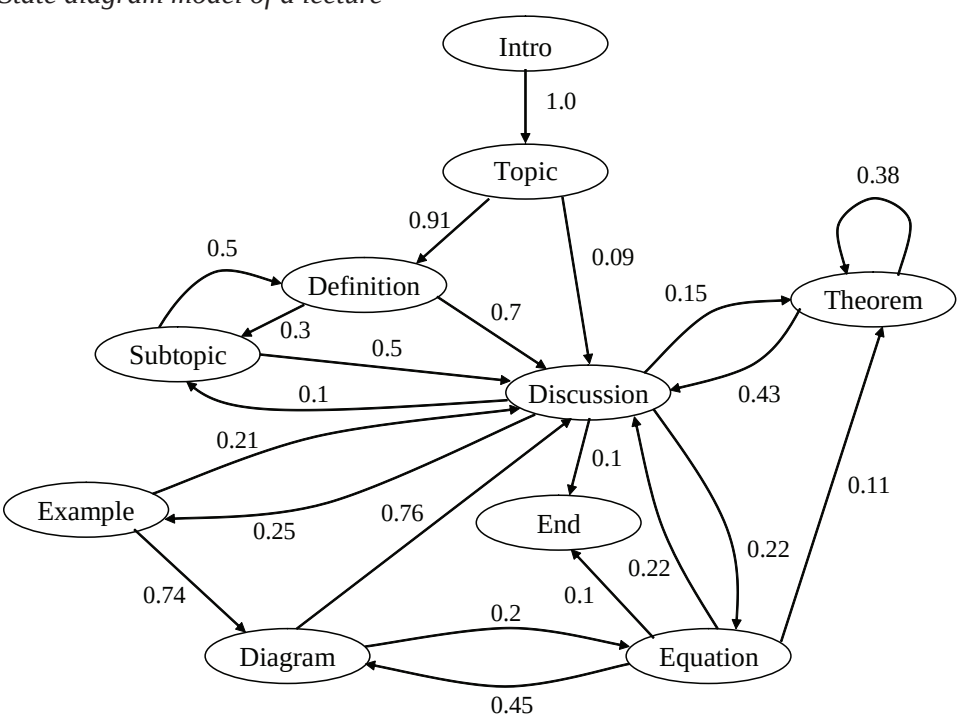
theoretical ones like Introduction to Algorithms. In this case, each lecture can be said to contain one or more topics. Each topic contains zero or more of the following:

- **Introduction:** general overview of the topic
- **Definitions and Theorems:** formal statement of core elements of the topic
- **Theory:** derivations with equations and diagrams
- **Discussions:** examples with equations and diagrams
- **Review:** repetition of key ideas
- **Question and Answer:** dialogue session with the students
- **Sub-Topic:** branch to a related topic

A simple state model for a video-based lecture can be represented as shown in Figure 1. This model for indexing e-learning videos is a state model consisting of 10 different states linked by maximal probability edges. Each state follows the probabilistic edges to go to another state. For example, from state Topic, one potential next state is Definition with a probability of 0.91 and another potential next state is Discussion with a probability of 0.09. Figure 1 shows the corresponding probabilities of transitions from one state to another based on our analysis of the SMA lecture corpus.

The state model implicitly encodes information about the temporal relationships between events. For instance, it is clear from Figure 1 that the introduction of a topic is never followed by a theorem without giving a definition. The state model, supplemented with our indexing techniques (discussed in later sections), provides useful information regarding the possible progression of topics in the lecture. For example, if a lecture is in the Discussion state and has some special attribute such as a camera zoom on the blackboard,

Figure 1. State diagram model of a lecture



we can say with a high level of confidence that it will go next to the Example state. Thus, the state diagram provides a framework for making inferences about lectures which can be used to determine the probable flow of pedagogical transitions that occur in the lecture.

Overview of Our Approach

Various camera motion techniques such as zooming in, zooming out, and panning can be extracted from educational videos. We match sequences of such camera motions to various states in the lectures, such as Theorem, Equation, and so forth (see Figure 1). In addition, we use the information available through the nonvisual media, including text from PowerPoint slides and audio from the lecture, to correctly correlate the heterogeneous media sources. Lastly, we are able to perform contextual searches for media content with minimal use of manual annotations.

The semantic analysis of raw video consists of four steps:

1. **Extract low- and mid-level features:** Examples of low-level features are color, motion, and italicized text. Some mid-level features are zoom-in and increased hand movement of the lecturer. Numerical representations of these features for a particular video segment are then assembled into a vector for subsequent processing.
2. **Classify the feature vectors into a finite set of states within the lecture:** States may correspond to Definitions, Emphasis, Topic Change, Q&A, Review, and so on. These are the objects and events identified in the lecture which are likely to be associated with semantically meaningful events.
3. **Apply contextual information to the sequence of states to determine higher-level semantic events:** such as defining a new term, reviewing a topic, or engaging in off-topic discussion.
4. **Apply a set of high-level constraints to the sequences of semantic events:** to improve the consistency of the final labeling.

Multimedia Feature Extraction and Analysis

Feature extraction is a widely accepted initial step towards video indexing. Features are interpretation-independent characteristics that are computationally derived from the media. Examples are pitch and noise for audio, and color histogram and shape for images. Experience across a wide range of multimedia applications has resulted in the identification of a large number of features that are useful for indexing (Gonzalez & Woods, 1992). The next step is to add semantics to the collection of features (e.g., high pitch in audio, pointing gestures, hand velocity, etc.) so one can use relationships among the features to infer the occurrence of higher level events (Gudivada & Raghavan, 1995).

MULTIMEDIA INDEXING FEATURES

The key influencing factor for the success of any video indexing algorithm is the type of features employed for the analysis. Many features have been proposed for this purpose (Idris & Panchanathan, 1997). Some are task specific, while others are more general and can be useful for a variety of applications.

Audio Features

There are many features that can be used to characterize audio signals. The three features of volume, spoken word rate, and spectral components have proven to be useful for lecture analysis. Volume is a reliable indicator for detecting silence, which may help to segment an audio sequence and determine event boundaries. The temporal variation in volume can reflect the scene content. For

example, a sudden increase in volume may indicate a transition to a new topic. Spoken word rate and recurrence of a particular word are indicators for the scope of a topic or cluster of words within a discussion (Witbrock & Hauptmann, 1997). Finally, spectral component features refer to the Fourier Transform of the samples of the audio signal. Analysis of the frequency components of audio signals using signal processing methods provides support for speaker change detection and other advanced tasks.

Video Features

A great amount of research has gone into summarizing and reviewing various features useful for video segmentation (Wang, Liu, & Huang, 2000). The color histogram, which represents the color distribution in an image, is one of the most widely used color features. The simplest histogram method computes the gray level or color histogram of two frames. If the difference between the two histograms is above the threshold, a boundary shot is assumed.

Motion is also an important attribute of video. Motion information can be generated by block matching or optical flow techniques (Akutsu, Tonomura, Ohba, & Hashimoto, 1992). Motion features such as motion field, motion histogram, or global motion parameters can be extracted from motion vectors. Other video features include texture, compression, and shape, which have been addressed in many papers. The features presented above have been used in different image retrieval systems to effectively perform a video segmentation.

Text Features

In the distance learning paradigm, text is one of the most important features that still has not been researched and utilized extensively. Ip and Chan (1998) propose text-assisted video content extraction, but only to synchronize the video with the text. Text extracted from PowerPoint slides, which are generally provided with educational videos, inherently stores a great deal of information, as we shall see with the SMA lectures.

INDEXING OF LECTURES

The most important and basic steps in a video indexing engine are to extract salient features and then combine these to get the most efficient indexes. A potentially rich source of pedagogical information is the blackboard activity during the presentation of the lecture, which in turn is highly correlated with the content of the lecture notes. Thus, a proper analysis of the lecture notes, which occur as PowerPoint slides, along with the properties discussed below provide an effective means for identifying pedagogical structures in the lecture video.

The PowerPoint slides that are distributed as lecture notes inherently store important information regarding the lecture, which is still largely untapped. Information in the form of the size, shape, color, and boldness of fonts reveals important aspects of the lecture. The state model for the educational videos discussed before enables us to divide the full lecture into four basic categories, namely: Definitions & Theorems, Examples, Proofs, and Formulae. In the analysis of the SMA lectures, we found that there exist stylistic conventions in the PowerPoint slides such as: all the important words (keywords with definitions) are in red and italicized; the special names are always in quotes; the slides having an example always have the word “example” in it; the questions and FAQs have a question mark in the particular slide; and the common names are always in square brackets. Some video features such as camera *zoom in* or *zoom out* to the blackboard or to the audience also specify a transition in the lecture from one state to another state, say

from Diagram to Discussion state. The rules for indexing the slides in the above-mentioned four categories can be summarized as follows.

Category 1: Definitions and Theorems

The keywords or defined terms are always red and in italics, so if there is a definition in the slide, it should have a red italicized word. The word *definition* or *theorem* may be present, but the string queried (the string is the set of words that one is searching for) must be found in the slide.

Category 2: Examples

The course material under consideration for Introduction to Algorithms has an associated image file for all the examples to represent special graphics or equations. The presence of the text pattern '*examples*' or '*examples:*' along with the string queried, is mandatory for a slide to qualify as one containing examples.

When analyzing the text, the context of the current slide is related to the previous slides. Figure 2 illustrates a case where a single example is presented in a sequence of slides. The sequence of processing steps for the well-known sorting algorithm called merge sort is illustrated in these slides. Progressive changes between consecutive slides provide evidence for labeling the associated video as the Example state. In the case of Figure 3, there is an example embedded in a definition as indicated by the word *example* found towards the bottom of the slide. Thus, the context of the particular example is linked to the contents above it and the topic currently being discussed.

Category 3: Proof

The word *proof* along with the string queried is assumed to be present in the slides having relevant information associated with the query. This assumption is a generalized one and can be used for all distance courseware.

Category 4: Formulae

Slides containing embedded formulae can be easily identified through the identification of special symbols used to represent the mathematical expressions. Queries for mathematical expressions can be resolved by converting the query expression into a string of characters and then performing

Figure 2. Slides illustrating the determination of context on the basis of text

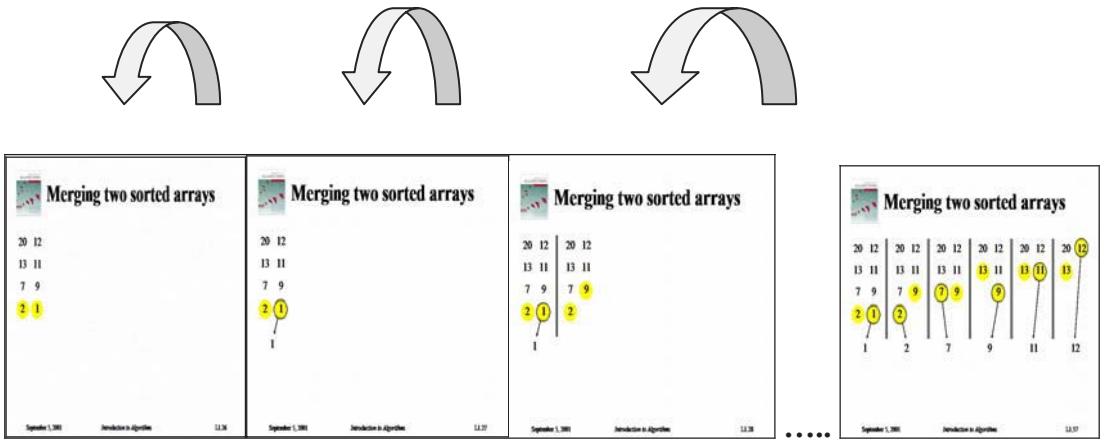


Figure 3. This slide shows the definition of a concept with an embedded example

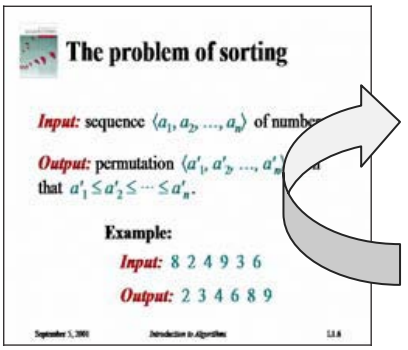

pattern matching. Special attention must be given to matching expressions that may assume alternate forms, such as fractions and summations.

This set of rules for indexing the slides is supplemented by video features to improve the overall quality of the video indexing. It is well known that video features taken in isolation are highly ambiguous. The video feature for *zoom out* may indicate either discussion in the class, the presentation of a definition, or simply a technique to reduce the tedium of the video (see Figure 4). Similarly, we find that the video feature *zoom in* may indicate the occurrence of the Topic, Example, Diagram, Theorem, or Equation states. Although there is a large overlap between pairs of features, the combination of multiple features given in Table 1 dramatically improves the accuracy of the state classification.

After the entire lecture has been classified, the labeled metadata can be used to perform multiple functions. The first one is searching in context. Several automatic frameworks exist for searching in context (e.g., Mittal and Altman, 2003). Here we employ a simple contextual searching algorithm. To enable searching in context, we need to manually enter the topic names for each video clip associated with a significant pedagogical event identified by the application of the classification rule set. Once the topic names have been keyed into the topic lists, we can then perform a contextual search just by searching for all occurrences of the queried subject and returning the results. This method is accurate because under our definition of the Topic state, all subject matter that is important enough to be explained separately is classified as a Topic or a Subtopic. For example, when *quicksort* is mentioned under the divide-and-conquer method (divide-and-conquer is a generic technique and quicksort is its specific application), our system classifies *quicksort* as a subtopic. Again, when *insertion sort* is compared with *quicksort*, it classifies *insertion sort* as another subtopic. As a result, the topic list is comprehensive in covering all material that is of importance. Hence, we are able to retrieve all instances of a particular query by searching through the topic list.

Figure 4. (a) Zoom in to the lecturer; (b) Zoom out to the room

Table 1. Summary of the video and text features

State	Video Features	Text Features
Topic	1) Zoom In 2) Stay Zoomed In 3) Underline on board	1) Slide Title
Definition	1) Zoom Out 2) Input and Output on board	1) Defined Word is Red Italicized 2) Presence of word Definition or Theorem along with defined word
Example	1) Zoom In 2) Ex: on blackboard	1.) Presence of word Example: or Examples along with topic 2) An associated *.gif file
Discussion	1) Zoom out for entire class 2) Change in voice OR 1) Zoom In on lecturer 2) Increased hand movement of lecturer	1) No or much less blackboard activity
Theorem	1) Zoom In 2) Theorem or Proof or Corollary in PPT 3) Same as (2) but on blackboard	1) Defined Word is Red Italicized 2) Presence of word Definition or Theorem
Formulae & Equation	1) Zoom In on blackboard	1) Associated *.gif file 2) Associated *.wmf file

EXPERIMENTAL RESULTS AND APPLICATIONS

The key idea is to create a system that automatically segments the educational videos so students can then use it to view the desired sections of the lectures without going through a linear search, thereby saving them time and effort. We tested our method on 26 lecture videos from the Singapore-MIT Alliance course SMA5503. The semiautomatic classification results are tabulated in Table 2.

Overall, our method has an accuracy of 85.1% in detecting the correct state. The personalization rules dependent on the first algorithm also have an accuracy of 85.1%. The contextual search algorithm is solely dependent on the correct clas-

Table 2. Experimental results for the detection of the lecture states

Topic	90
Definition	80
Discussion	86
Theorem	87.5
Example	83
Equation	62
Diagram	92.3

sification of the topic state and has an accuracy of 90%.

Further, we are able to efficiently and accurately search in context throughout the video database. For example, by searching for the string *merge sort*, we return not only the video clip that teaches *merge sort*, but also other clips from other lectures where some aspect of *merge sort* is further explained (see Figure 5). In this particular case, *merge sort* is mentioned in video lecture 1 under the topic Sorting. It is also mentioned again in lecture 3 under Time Analysis, and in lecture 7 where it is compared to *quicksort*. Hence, when a student uses this system to search for *merge sort*, he has immediate access to all three related video clips even though they are taught in completely different lectures and different parts of the course. As a result, a student searching for *merge sort* will get a much clearer idea of how it actually works and all its different aspects. The combination of semiautomatic analysis of lecture videos to identify pedagogical events and key topics along with techniques for discovering emergent semantics from the media metadata provides the student valuable insights into the finer concepts of the queried subject. By using a simple user interface, users can enter keywords, view topic associations, and search for related materials as shown in Figure 6 (Altman & Wyse, 2005).

CONCLUSION

This chapter presents a system for indexing videos using audio, video, and PowerPoint slides and then segmenting the video content into various

Figure 5. Search for Merge Sort

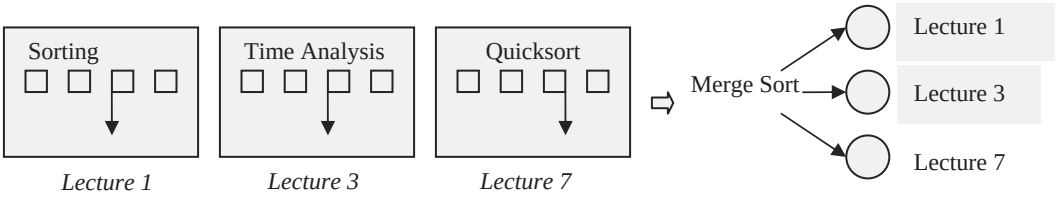

Figure 6. Graphical user interface (GUI) for the presentation of lecture content in response to a query

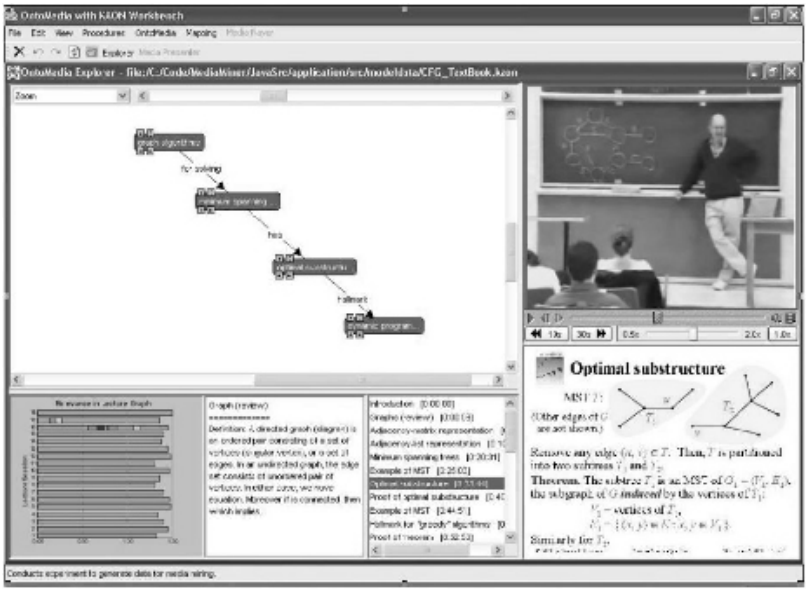

lecture components. The use of multiple media sources ensures accuracy in the classification of lecture content. This is of critical importance for the effective support of e-learning tasks and maintenance tasks performed by students and instructors. By dynamically manipulating these lecture components, we are able to personalize the lecture videos to suit individual needs. This helps to make the videos more suitable for absorption of the subject matter by students. While full-text indexed retrieval systems have been proposed earlier, our method is more efficient as it uses all forms of media to segment and index the video. It also allows us to perform efficient contextual search with a minimum of human supervision. Future integration work will focus on increasing the automation of media analysis for the courseware and the automatic construction of media models. Additional work on an enhanced learning environment involves the creation of query mediation tools that bridge the gap between the semantically labeled media and a domain ontology. The combination of media models and query mediation will enhance insight generation and provide support for the personalized construction of knowledge by the individual student.

Chapter 5.10
Using Multimedia and Virtual Reality for Web-Based Collaborative Learning on Multiple Platforms

Gavin McArdle
University College Dublin, Ireland

Teresa Monahan
University College Dublin, Ireland

Michela Bertolotto
University College Dublin, Ireland

ABSTRACT

Since the advent of the Internet, educators have realised its potential as a medium for teaching. The term e-learning has been introduced to describe this Internet-based education. Although e-learning applications are popular, much research is now underway to improve the features they provide. For example, the addition of synchronous communication methods and multimedia is being studied. With the introduction of wireless networks, mobile devices are also being investigated as a medium to present learning content. Currently, the use of 3-dimensional (3D) graphics is being explored for creating virtual learning environments online. Virtual reality (VR) is already being used in multiple disciplines for teaching various tasks. This chapter focuses on describing some VR systems, and also discusses the current state of e-learning on mobile devices. We also present the VR learning environment that we have developed, incorporating many of the techniques mentioned above for both desktop and mobile devices.

INSIDE CHAPTER

E-learning has become an established medium for delivering online courses. Its popularity is mainly

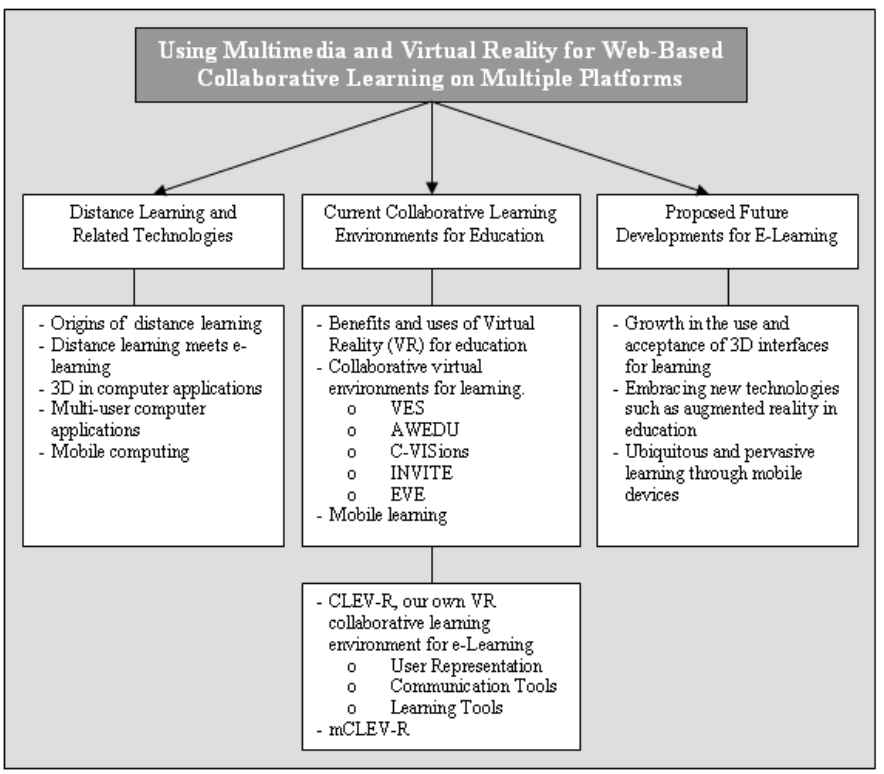
due to the convenience and flexibility it provides for users, allowing them to learn without time or location restrictions. Many different e-learning systems are currently available, the majority of which are text-based and allow users to contact the course tutor via electronic mail or discussion forums. These courses essentially offer access to a common pool of resources that allow users to gain knowledge and often qualifications. Researchers are now exploring new ways of making the online learning experience more engaging and motivating for students. Multimedia and communication technologies are being added, and together with 3D graphics, are fast emerging as a means of creating an immersive online learning experience. With the advent of mobile technologies, m-learning is showing promise as an accompaniment to online courses, offering the prospect of a modern and pervasive learning environment.

This chapter discusses the benefits 3D environments offer the e-learning community. We outline how this type of system emerged and describe some currently available systems using these new technologies. In particular, we describe in detail our own virtual reality environment for online learning and the features it provides. We discuss the extension of this system to a mobile platform so that users have anytime, anywhere access to course materials. Finally, we put forward some thoughts on future technologies and discuss their possible contribution to the development of a truly ubiquitous and pervasive learning environment.

INTRODUCTION

Distance learning has gone through a number of iterations since its introduction in the 1800s. The

Figure 1. Chapter overview



notion of distance learning grew mainly out of necessity, and helped to overcome geographical, economical, and cultural barriers that prevented people from partaking in traditional classroom-based education. Over the years a number of distance learning applications have emerged to address these issues. The evolution of such systems can be clearly linked to the technological developments of the time. This chapter focuses on giving a brief overview of the changes in distance learning from its inception to today, before concentrating on the distance learning technologies currently in use. We provide details of how the latest technologies and demand from students have led to the development of 3-dimensional (3D) e-learning systems. We also look to the future, suggesting what the next generation of technology can bring to distance learning. We pay particular attention to the need for ubiquitous and pervasive means of e-learning, and in doing so describe our own system, which uses state of the art technologies to deliver learning material to students both on a desktop computer and while they are on the move.

In the background section, we describe how distance learning has evolved from a simple postal service offered by universities to a sophisticated tool that utilises the convenience of the Internet. As the discussion progresses toward the introduction of 3D graphical environments to distance learning applications, the origins of 3D graphics and their uses are also presented. Multi-user environments for distance education is a major area of research at present, and so the latter part of the section provides a synopsis of the history of multi-user computer applications. We also present a brief discussion on the current uses of mobile technologies, which are now emerging as promising tools for e-learning.

In the main section of this chapter, we describe how recent technological advancements and requirements of students and tutors have led to a new breed of computer-based learning systems utilising the latest 3D graphics and communication tools. We detail a number of such systems outlining their strengths and weaknesses, in particular the system we are developing, which attempts to address some of these weaknesses. We describe how it uses the latest technologies to deliver a collaborative multi-user 3D learning system to students at fixed computer terminals and mobile devices. Finally we hypothesise how the current use of augmented reality (AR) technologies can be adapted to form a truly ubiquitous and pervasive learning environment. A summation and discussion of the chapter is provided in the concluding section.

BACKGROUND

This section gives the reader an overview of how distance learning has evolved from its early days as correspondence courses to the modern Internet based learning solution. It also charts the progression of computer-based 3D and multi-user tools, hinting at how they can be combined to form a new type of distance learning system. This new learning paradigm is made all the more powerful when combined with the latest mobile technologies, and a short overview of this emerging technology is provided below. Figure 2 provides an overview of the literature reviewed in this chapter, while Figures 3 and 4 highlight the main points of discussion in each subsection.

A Brief History of Distance Learning

Distance learning is a form of education that has emerged out of necessity. It is not always possible for a student and instructor to be present at the same location at the same time. Distance learning is not a new concept, and has been in use since the 1800s. Today, it can take a wide variety of forms, including correspondence courses, video and radio broadcasts, and e-learning. One of the earliest forms of distance learning was a correspondence course. Traditionally, these courses were a form

Figure 2. Background

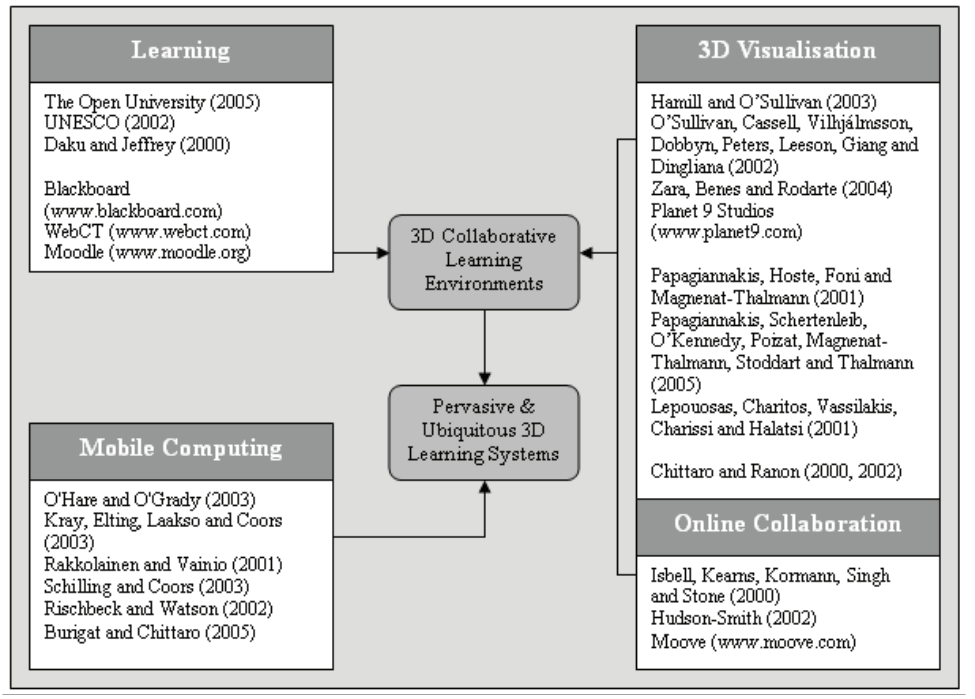


Figure 3. Progression of distance learning

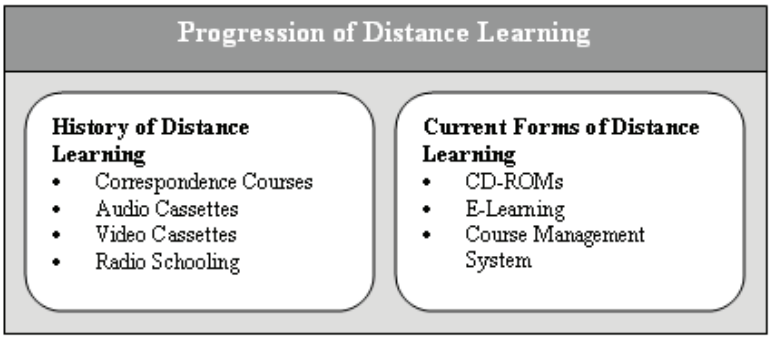
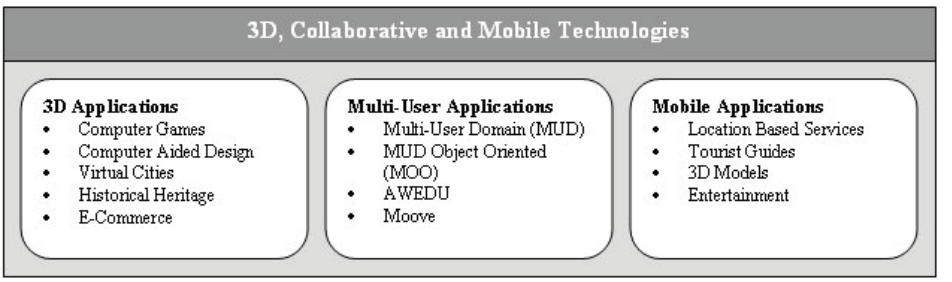


of home study. Students receive printed or written course material via the postal service, complete assignments, and return them to their tutor for appraisal. These courses were later augmented with different types of media. For example, the Open University (2005) offered lectures on audio and video cassettes in the 1980s.

One major drawback of this form of distance education was the lack of interaction between student and teacher. Radio schooling provided a solution to this issue. Again, radio schooling is a form of home study, mainly used for primary and secondary education; pupils in remote locations can use a two-way radio to communicate with teachers and receive their assignments. This type of learning proved popular in Australia in the 1980s, and was particularly effective where large numbers of people lived in remote locations. Today it is being used in Africa to provide primary education for pupils in remote towns and villages (UNESCO, 2002). One of the key advantages radio schooling provided over the

Figure 4. 3D, collaborative, and mobile technologies



more traditional correspondence courses was the instant feedback between student and tutor. With the advancement of technology, this type of one-to-one distance education has now become much more attainable. Indeed, the advent and widespread growth of computer technology has introduced many additional communication and interactive features to distance learning, moving it forward into the realm of e-learning.

Distance Learning Meets E-Learning

E-learning is a term given to any form of learning which involves the use of an electronic medium to display learning material. Early forms of e-learning involved teachers demonstrating certain lessons to students through computer-based animations and simulations. CD-ROMs were then developed and soon became a popular accompaniment to textbooks. Students could use these CD-ROMs to further understand the book's content, and also as a study aid. Distance learning courses can also utilise this technology to distribute course material. The use of CD-ROMs means that the students' learning experience can be much more interactive and that learning content can be represented in different formats, including sound and video clips. For example, when studying historical events, news footage from the era can be displayed via the CD-ROM, helping to bring the learning material to life. CD- ROMs often provide interactive games (e.g., counting games) for younger students, helping them to improve their numerical skills. Automated quizzes provide instant feedback of a student's knowledge of a subject area. Daku and Jeffrey (2000) describe one such CD-ROM used for teaching, MATHLAB, a statistical application; it acts as a standalone tool for learning the functionality of MATHLAB. Experimental results have shown that students preferred learning using the CD-ROM rather than the traditional lecture/assignment format.

Over the last 10 years the popularity of the Internet as an information source has grown extensively. Its shear diffusion and convenience is ideal to disperse learning content for distance education. In general, Web sites are designed where tutors upload course material, including text, quizzes, and links to external knowledge sources. Registered students can then access this learning material and study it at their own pace. Course work can be submitted to the tutor using e-mail, and likewise students experiencing problems may contact tutors via e-mail. There are numerous examples of this type of distance learning system in use today. For example, the University of Colorado and the University of Illinois provide these kinds of courses. Indeed, many schools and universities now also use Web-based learning as an accompaniment to traditional classroom and lecture-based lessons.

Realising the importance and benefits of using the Internet for distance learning, much research is underway to improve the services and facilities

that such learning portals can offer. Initially these Web sites were a mere bank of knowledge, simply providing the course material in HTML (Hyper Text Mark-up Language) format for students to access, read, and learn. Today, they are far more sophisticated. A number of successful companies have emerged which offer online course management tools for tutors to intuitively present course notes, lecture slides, and additional material online. All management, such as access rights and course registration, are provided by these applications. Blackboard (*www.blackboard.com*) is one such course management system, designed to facilitate teachers with the management of their online courses. It has been adopted as the e-learning platform by more than 2200 institutions, including Harvard University, the University of Maine, and the University College Dublin (Wikipedia, 2005). Web Course Tools (WebCT, *www.webct.com*) is another company involved in the provision of e-learning systems. Founded in 1995, it is currently the world's leading provider of e-learning systems, with institutes in over 70 countries relying on them for e-learning software. Like Blackboard, WebCT is an authoring environment for teachers to create online training courses. While these systems tend to be extremely costly, free systems with open source code have also been developed. Moodle (*www.moodle.org*) is one such learning system, which is in widespread use at institutions such as Dublin City University, University of Glasgow, and Alaska Pacific University, and looks like becoming the industry standard. Development of Moodle has been ongoing since 1999, and already it has a large user base. It offers a range of software modules that enable tutors to create online courses. One area that Moodle tries to address is the need for pedagogical support; this aspect is largely neglected in commercially available applications. In particular it promotes the notion of constructionist learning, where a student learns from his or her own experiences, resulting in a student-centred learning environment.

The current state of e-learning, and in particular distance learning, has been outlined above. Following the success of computers as a learning tool, much research is underway to enhance a user's learning environment**.** In particular, one area that is being researched is the use of 3D graphics in these systems. It is the examination of the use of 3D graphics and multimedia, combined with collaborative tools and mobile technologies within e-learning, that forms the focus of this chapter. The remainder of this section provides a brief description of the use of 3D graphics on computers, from their early days in computer games to its current role in visualisation. We also examine the emergence of 3D graphics on mobile devices such as personal digital assistants (PDAs). This section gives an insight into the previous use of collaboration tools and multi-user interaction on computers before the next section gives a detailed review of learning systems utilising these technologies.

3D, Collaborative, and Mobile Technologies

3D Computer Applications

For some time, 3D graphics have been an established means of entertainment, in particular within computer games. In 1993, ID Software released Doom, a first person shooter computer game. Like its predecessor Wolfenstein, 3D released in 1992, Doom was built using pseudo-3D, where images placed on a 2D plane give the impression of a 3D environment. The immersive game environment included advanced features such as stereo sound and multilevel environments with increased interaction for players. The popularity of these games and the 3D paradigm led to a succession of immersive 3D computer games using this formula, and ultimately led to the worldwide acceptance of this form of immersive environment. As technology improved, the complexity of the graphics used in such computers games increased.

Today in games such as Half-Life, developed by Value Software, users take on roles of characters in stories with life-like scenes. Add-ons enable multi-user support for players to interact with each other in the game, although they may be geographically distant.

Another domain where 3D has been used for a long time is modelling; in particular engineering and architectural models can be effectively and efficiently modelled on a computer using 3D graphics. AutoCAD, developed by AutoDesk, is a computer aided drafting software application first developed in 1982 for use by mechanical engineers. It allows both 2D and 3D representation of objects to be rendered and has fast become the industry standard. This form of modelling objects enables designers and customers to see how objects will look before they are built. Today property developers often produce 3D Virtual Reality (VR) models of houses in order to entice prospective buyers. This can be taken one step further as developers produce models of how new builds will affect the aesthetics of an area. Another area of interest in the research arena is that of modelling cities. Hamill and O'Sullivan (2003) describe their efforts in producing a large-scale simulation of Dublin City. The goal of their research is to allow users to navigate freely around the streets of Dublin. The city can be used as a test-bed for related work, such as simulating crowds in virtual environments (O'Sullivan, Cassell, Vilhjálmsson, Dobbyn, Peters, Leeson, et al, 2002). Zara, Benes, and Rodarte (2004) have produced a model of the old Mexican city of Campeche. This Internet-based application acts as a tourist aid and promotes the area as a tourist attraction. The area of urban modelling has much commercial interest. Planet 9 Studios (*www.planet9.com*), based in San Francisco and set up in the early 1990s, produces accurate and intricate 3D urban models for use in such diverse activities as homeland defence, military training, and tourism. It is tourism that has long been a driving force behind much of the development of the VR cities and has also led to a number of similar applications aimed at visitors and tourists. MIRALabs in Geneva have been investigating the area of virtual heritage. Much of this research focuses on enabling realistic models of historical sites to be created efficiently and in a means suitable for use on basic machines (Papagiannakis, Hoste, Foni, & Magnenat-Thalmann, 2001). Today, the work of MIRALab in the field of historical reconstructions involves the use of mixed realities; that is, augmenting real-world sites with VR 3D models of people and artefacts that would have once been there (Papagiannakis, Schertenleib, O'Kennedy, Poizat, Magnenat-Thalmann, Stoddart, et al, 2005). The benefits of using VR to host exhibitions in museums are outlined by Lepoursas, Charitos, Vassilakis, Charissi, and Halatsi (2001), where details on designing, such an exhibition, are also provided.

Several of the projects mentioned above use special features to allow users to interact with the environment. Often the environment acts as a 3D-Graphical User Interface (GUI) to access underlying information. E-commerce or purchasing products and services using Web sites on the Internet have long been popular. The number of people buying through this medium has increased dramatically over the last five years. According to Johnson, Delhagen, and Yuen (2003), online retail in the United States alone will have reached $229.9 billion by 2008, and so this is a natural area for researchers to investigate. While research has contributed to many improvements in this form of shopping, one area that is still emerging is the use of a 3D interface to browse for goods. Chittaro and Ranon (2002) have designed a virtual environment mimicking a traditional supermarket, where virtual products are placed on virtual shelves. Users navigate the store, selecting items they wish to purchase. They argue that this is a more natural way for consumers to shop online because it is more familiar to shoppers compared to lists of available items. These 3D department stores can be tailored and personalised to an individual user (Chittaro & Ranon, 2000). This

can involve personalising the look and feel of the environment and user profiling to position relevant items in prominent positions. The extension of this 3D store paradigm to a multi-user platform is also discussed and proposed, where a number of shoppers are present in the one store. This, however, has drawbacks and provides difficultly in adapting the store for individuals. The next section provides a synopsis of the origins of multi-user computer applications and provides some details of their current uses.

Multi-User Applications

One of the earliest forms of multi-user interactivity using computers took the form of multi-user domains, known as MUDs. MUDs first appeared in 1978, and being primarily used for computer gaming purposes, quickly became popular. In a MUD, a text-based description of an environment is provided, with each user taking on the role of a character in that environment. Interaction with the system and with other users is achieved by typing commands in a natural language. Usually a fantasy game featuring goblins and other creatures, the purpose was to navigate through the virtual environment, killing as many demons as possible. While initially developed for entertainment, people saw the possibility of using this technology for other purposes, notably as a form of distance learning and as a means of virtual conferences. This move away from the use of MUDs for gaming led to the developments of a MOO (MUD Object Orientated) at the University of Waterloo in 1990. Again, MOO systems are text-based virtual environments, which were initially an academic form of a MUD. Isbell, Kearns, Kormann, Singh, and Stone (2000) discuss LambdaMoo, one of the longest running MOOs, created by Pavel Curtis in 1990. Today, it offers a social setting for connected users to engage in social interaction with similar functionality to that found in a chat room or online communities.

Improvements in technologies, along with increases in Internet connection speeds, have enabled a move away from the traditional text-based environments to more graphical-based communities. These communities, such as Active Worlds (Hudson-Smith, 2002), offer the same interaction as chat rooms. However, the rooms are designed as physical spaces complete with scenery and furniture. Each user is shown on-screen in the form of an avatar, a graphical representation visible to other users. A further extension of this type of environment is seen in the 3D online world of Moove (*www.moove.com*). Here, users maintain their own rooms in the 3D environment, which they can decorate to their own tastes and use to host chat sessions. Voice and video chat can also be used in many of the modern online 3D communities. In recent times, this type of 3D environment has been used for education, and this will be discussed later in this chapter.

Mobile Applications

In recent years, the use of mobile devices such as PDAs and cell phones has become prevalent, and this has led to a lot of research into providing applications on these devices. The widespread introduction of wireless networks has increased the use of these devices dramatically, and has helped fuel research in this area. People can now browse the Internet, send electronic mails (e-mails) and access their personal files while on the move. Many different applications have been developed for this mobile platform, the most popular of which utilise a global positioning system (GPS). These applications use a system of satellites and receiving devices to compute positions on the Earth, and therefore enable people to gain information relative to their position in the world. They are thus used mainly in providing location-based information to users, and in particular many tourist applications have been developed to help people find their way around foreign cities. For example, O'Hare and O'Grady

(2003) have developed a context-aware tourist guide, which tracks a user's position and displays multimedia presentations for different attractions as the user approaches them. Their system uses images, videos, sound, and text to give the tourist information about the attraction. Kray, Elting, Laakso, and Coors (2003) developed an application to provide boat tourists with route instructions and information on services nearby.

A recent development in mobile technologies is the use of 3D graphics on these devices. Many large-scale 3D models have been successfully developed for use on laptop computers, but the challenge now is to extend these to smaller platforms, such as PDAs and even mobile phones. Rakkolainen and Vainio (2001) developed a Web-based 3D city model of Tampere and connected it to a database of relational information so that users can query the system about services available in the city. They customised it for mobile users by integrating a GPS receiver and have developed a fully working version for laptops. However, their 3D model is much too large to run on smaller devices such as PDAs, so they use only images and Web pages for these devices. Schilling and Coors (2003) have developed a system that provides a 3D map to help present route instructions to mobile users. In their model, landmarks and buildings of importance are visualised in detail through the use of textures, while less important buildings are rendered in grey. A user trial was carried out on a laptop running a mobile phone emulator. Results proved positive, with most users stating they would prefer to use the 3D maps than 2D paper maps and guidebooks. However, users did suggest that the 3D model should be more detailed and more realistic.

The major problem for extending these models to smaller mobile devices is their size in relation to processing power available, together with the users' desires for more detail and realism. Many researchers are exploring ways to achieve this using various culling techniques, parallelism, and information filtering (Burigat & Chittaro, 2005; Rischbeck & Watson, 2002). Smaller 3D models can, however, be displayed on smaller devices and are used in a variety of games on handheld devices and mobile phones, providing entertainment for their user. ParallelGraphics, a world leader in the provision of Web3D graphics solutions, describe uses of 3D for mobile devices, such as sales and marketing, real estate, and field maintenance.

The technologies presented in this section have been widely accepted by developers and computer users. As the next section shows, they have recently received attention from the educational research community. They show promise as a means of presenting learning material to students in an engaging and motivating way. A number of such systems using these technologies are presented in the following section before we discuss our own learning system, CLEV-R, which provides solutions to some of the issues that existing learning systems fail to address. In particular, the need for a range of communication and collaborative tools for both learning and socialising is dealt with. Also presented is a pervasive ubiquitous learning environment we developed for use on mobile devices as an accompaniment to the desktop system.

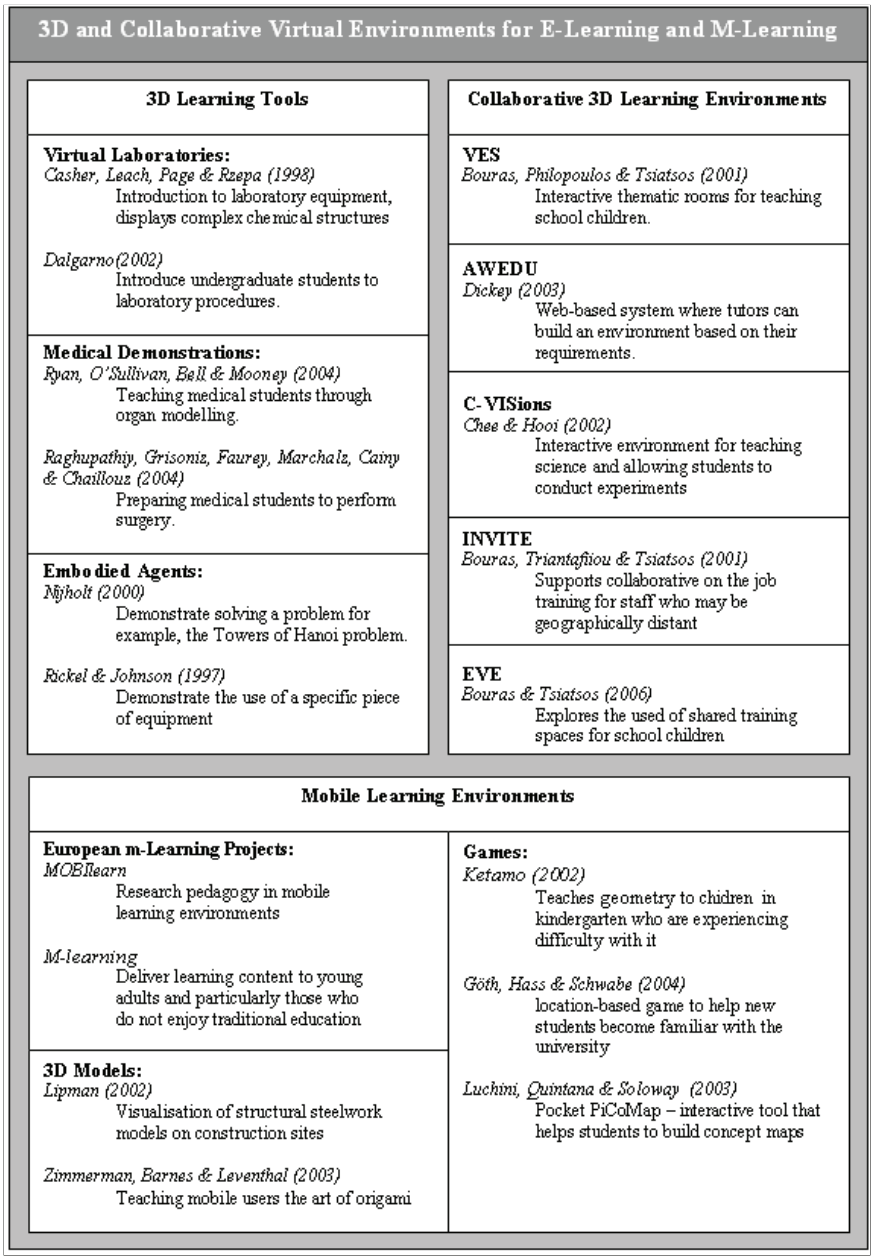
3D AND COLLABORATIVE VIRTUAL ENVIRONMENTS FOR E-LEARNING AND M-LEARNING

This section details the use of 3D as a learning aid. Firstly, we consider its use as a visualisation tool, and then discuss how multi-user technologies are being combined with 3D graphics to create effective online learning environments. We also discuss some current research into the provision of learning tools on mobile devices. Figure 5 provides an overview of the topics presented below.

3D Learning Tools

In addition to the uses of virtual reality (VR) and 3D graphics discussed in the previous section, these techniques have also been extended in vari-

Figure 5. 3D and collaborative virtual environments for e-learning and m-learning



ous ways for use in education. The ability of these tools to model real-world objects and visualise complex data makes them an ideal learning tool. Users can explore these objects, interact with them, and discover their various features. Furthermore, the visualisation of complex data can greatly aid a person's comprehension of it. Thus, these models provide users with an intuitive way to learn about natural objects by presenting them in a visually appealing way. As such, many 3D resources for education have been developed, both for online and individual applications.

Scientific and engineering visualisations use VR to represent complex chemical structures

and to present experimental data in a more visual manner in order to gain a better understanding of the results. Casher, Leach, Page, and Rzepa (1998) describe the use of VR for chemical modelling, and outline the advantages that animation can bring to these models. They also describe how a virtual laboratory can introduce students to various laboratory instruments. In addition, Dalgarno (2002) has developed a virtual chemistry laboratory that allows undergraduate students to become familiar with the layout of the labs, and also to learn about procedures to follow while in the laboratory. VR has more recently been introduced in the field of medical training. Its use varies from modelling different organs and allowing students to interact with them freely to developing training application for specific procedures. Examples include Raghupathiy, Grisoniz, Faurey, Marchalz, Caniy, and Chaillouz (2004), who developed a training application for the removal of colon cancer, and Ryan, O'Sullivan, Bell, and Mooney (2004), who explore the use of VR for teaching electrocardiography. The major advantage of using VR in medicine is that students can repeatedly explore the structures of interest and can interactively view and manipulate them. Real training cases can be hard to come by, and so this extra practice and experience can be invaluable. Also, patients are not put at risk by having inexperienced students carry out procedures on them.

3D models can also be particularly useful in teaching younger students. Many games have been developed using 3D images that the user must interact with in order to learn a certain lesson. Interactive models increase a user's interest and make learning more fun. 3D animations can be used to teach students different procedures and mechanisms for carrying out specific tasks. Some researchers have combined the benefits of 3D and software agent technologies to provide intelligent models to teach certain tasks. For example, Jacob is an intelligent agent in a VR environment that guides the user through the steps involved in solving the towers of Hanoi problem, as described by Nijholt (2000). By following the directions of Jacob, the users learn how to solve the problem themselves. Likewise, STEVE, described by Rickel and Johnson (1997, 1999), is an intelligent agent that has been developed for use in naval training to show individuals or groups of students how to operate and maintain complex equipment. STEVE can demonstrate certain tasks and then observe while users carry out these tasks, correcting them when mistakes are made.

Collaborative 3D Learning Environments

VR also allows for the development of complete virtual environments that users can "enter" and navigate through as if it was a real environment. The most immersive of these environments require the user to wear a head mounted display and tracking gloves, while other VR environments are displayed on desktop computers, where users interact through the mouse and keyboard. As shown in the previous section, virtual environments like these have evolved from computer games, but are fast emerging in other areas such as e-commerce, chat-rooms, and indeed education. E-learning in particular is an ideal target for the development of an immersive VR environment. Here an entire VR environment is designed where all the learning takes place. This kind of system represents a shift in e-learning from the conventional text-based online learning environment to a more immersive and intuitive one. Since VR is a computer simulation of a natural environment, interaction with a 3D environment is much more intuitive than browsing through 2D Web pages looking for information. These environments tend to be multi-user, exploiting the notion of collaborative learning where students learn together. The benefits of collaborative learning have been researched extensively and are outlined in Laister and Kober (2002) and Redfern and Naughton (2002). The main advantage of this type of learning is that users no longer feel alone or isolated. This

feeling of isolation can be particularly prevalent in online learning, where students do not attend actual classes or lectures. Thus, multi-user learning environments have proven very popular for online learning. The VES, AWEDU, C-VISions, EVE, and INVITE systems all concentrate on developing collaborative learning environments using VR to further immerse students in their learning. The following paragraphs outline the main features of these systems before we discuss our own research and what it has to offer.

In 1998, Bouras, Fotakis, Kapoulas, Koubek, Mayer, and Rehatscheck (1999) began research on virtual European schools (VES), the goal of which was to introduce computers to secondary school students and encourage teachers to use computers in the classroom. VES uses 3D to provide a desktop immersive environment. A different room in the 3D environment is used for each school subject, and these themed rooms provide information about the specific subject in the form of slide shows and animations, as well as links to external sources of information. The VES project was carried out in conjunction with book publishers, and these publishing houses provided much of the content that is displayed in the environment. VES is an example of a multi-user distributed virtual environment (mDVE). In an mDVE, more than one person can access the environment at the same time, and users are aware of one another. In the VES environment users can "talk" to each other using text chat facilities. The evaluation of VES took the form of questionnaires, which students and teachers completed. The results, which are presented in (Bouras, Philopoulos, & Tsiatsos, 2001) show that navigation in the 3D environment was difficult, the user interface was old fashioned, and there was not enough content to keep students amused and entertained. These points were taken on board and the system was improved. When launched, VES was used in 4 countries and had the cooperation of more that 20 publishers.

The Active Worlds Universe, a very popular and powerful Web-based VR experience, is a community of thousands of users that chat and build 3D VR environments in a vast virtual space. As discussed earlier, it provides thousands of unique worlds for shopping, chatting, and playing games. In 1999, an educational community known as the Active Worlds Educational Universe (AWEDU) was developed (Dickey, 2003). This is a unique educational community that makes the Active Worlds technology available to educational institutions. Through this community, educators can build their own educational environment using a library of customisable objects, and can then place relevant learning material in their environment. Through these environments, users are able to explore new concepts and learning theories and can communicate using text-chat. Users are represented in the environment by avatars which help them feel better immersed in the educational environment. Students from all over the world can be connected through this system, and it therefore aids cultural sharing and social learning. The AWEDU environment is extremely versatile and may be used for a number of types of learning. Dickey (2003) presents the use of the environment as a form of distance education within the university. Riedl, Barrett, Rowe, Smith and Vinson, (2000) provide a description of a class held within the Active Worlds environment. The course was designed for training teachers on the integration of technology into the classroom. Nine students took part in the class; their actions and group discussions were recorded during their online sessions and, along with results from questionnaires, are presented in the paper. While the majority of students were pleased with the freedom the virtual environment offered, not all adapted to this new form of learning. The evaluation discovered that one of the major benefits of this type of learning was that students were aware of the presence of others in the shared environment and this interaction with others kept students interested and motivated.

C-VISions was launched in 2000, and is a collaborative virtual learning environment that concentrates on supporting science learning. The system presents learning stimuli that help school children understand fundamental concepts from chemistry, biology and physics. C-VISions encourages active learners; students can run science experiments in the virtual world and view the outcomes as they change simulation parameters. Chee and Hooi (2002) describe their physics environment and in particular the Billiard World, a simulation to help students learn about mass, velocity, acceleration, conservation of momentum, friction, and the coefficient of restitution. This world contains a billiard table with two balls and a cue stick. Users can interact with a number of "live" objects that are provided within the world. For example, the cue stick can be aimed at a ball and then used to strike it. Students can replay the most recent simulation and can view the plotting of graphs of that event synchronously. This helps the students see the relation between their action and how it is plotted on a graph. It therefore helps them to understand the graph representations. Users can navigate around the world and change their viewpoints using buttons provided. The system is multi-user, and so events happening in one user's environment are propagated to all other connected users. Users may share video resources, and shared electronic whiteboards are also provided. The system provides a Social World where students can mingle and student-student communication is supported through text and audio chat. Chee (2001) describes a preliminary evaluation of the first prototype of this system. The study revealed that all students found the system "an enjoyable way to learn" and each felt they gained a better sense of understanding about the subject matter. Some problems using the collaboration tools were highlighted. For example, students found it difficult to work together on group tasks. This was put down to inexperience using the tools. While this study was small, involving only three students, the results proved encouraging that this type of 3D environment has something to offer students.

In April 2000, a consortium of companies and institutions began research into the design and development of a multi-user 3D collaborative environment for training. The goal of the environment was to support group learning, in particular on-the-job training, without the need for all those involved to be in the same location at the same time. Moving away from the traditional videoconferences, this system known as INVITE, the Intelligent Distributed Virtual Training Environment, had a fundamental objective of making people feel that they are working as a group rather than alone in front of a computer. The technologies required for such a system are described by Bouras, Triantafillou, and Tsiatsos (2001), along with implementation issues of the multi-user architecture. The project focuses on the importance of a social presence and the general sense of belonging within a learning environment, presenting the notion of photo-realistic avatars as a way to achieve this. The system design allows synchronous viewing of e-learning content within the 3D environment through a presentation table. Users can see pictures, presentations, 3D objects and prerecorded videos simultaneously, and collaboration is provided through application sharing. An initial prototype of the system was developed, and a first evaluation showed that INVITE could be a powerful tool for collaborative learning with test-users enjoying learning in the virtual environment. The INVITE project terminated prematurely, and so the main contribution it made to the area of virtual learning environments was a detailed system specification and outline of features that should be included in such a system.

The research group from the University of Patras in Greece who were involved in the development on the INVITE Project continued their work, leading to the development of EVE (Educational Virtual Environments). Like INVITE, EVE is a Web-based, multi-user envi-

ronment that explores the use of shared virtual spaces for training. Their system addresses two main challenges. The first was a technological challenge to develop a learning environment that resembles the real world and that provides additional functionality to enhance the users' experience. Secondly, the pedagogical challenge of making an educational model that contributes in the most efficient way to the distribution of knowledge. EVE is organized into two types of place for each user, their personal desk space and the training area. The personal desk refers to a 2D place where all the asynchronous features of the system relating to that user can be accessed. Thus a user can access course and user information, upload and download files, view and reply to personal messages, and manage their profile. The training area is the virtual classroom where learning takes place, and consists of a presentation table, a whiteboard, and avatar representations for all connected students and a tutor. Features such as application sharing, brainstorming, and text and audio communication are also supported. The tutor has control over the course, learning material, and students. They decide what course content is displayed on the presentation board and when students may ask questions, and can also assign students to breakout session rooms during an e-learning class and monitor their text chat sessions. An evaluation of the system, provided by Bouras and Tsiatsos (2006), shows that test-users found the system interesting and promising for e-learning. The test users were chosen from a number of Greek schools and a teacher from each selected school also evaluated the system. The users' social presence and the intuitive virtual environment were highlighted as advantages of the system. Collaboration tools such as audio and text communication, application sharing, and visualisation on the presentation table also proved popular. Overall the feedback was positive, with both students and teachers seeing the appeal and usefulness of the 3D paradigm. Feedback was also taken from students about possible improvements that could be made to the system. The introduction of facial expressions, along with tool tips for assisting during navigation, are discussed. The future work of the EVE project therefore involves the implementation of these changes along with the addition of new rooms to the environment to support smaller groups for project work.

Mobile Learning Environments

The use of mobile devices for learning, termed m-learning, has been another area of interest for researchers of late. Their portable nature makes them convenient for many people to use while on the move. Therefore, the extension of e-learning to these devices seems a natural progression. While laptop computers are widely popular and capable of delivering large amounts of information efficiently, smaller mobile devices, such as PDAs, also show promise for learning. Oliver and Wright (2003) outline the main advantages of PDAs as their light weight and portability, their ease of use, and their low cost. Also, most are wireless enabled. Csete, Wong, and Vogel (2004) accredit the functionality provided on these devices as a reason for their growing popularity. Most mobile devices now include an address book, calendar, to-do list, and memo pad. Wireless enabled devices provide e-mail and Web browsing, and most support flash, audio, and movie files. Indeed, their functionality is continually increasing as companies are now developing versions of their software for these devices. Disadvantages of these devices, such as small screen size and limited processor power and memory, mean that applications for them must be lightweight and content needs to be adapted for this new platform. These drawbacks are, however, outweighed by their inexpensive and convenient nature, which makes them the ideal target for a learning application. The major advantage this mobile platform brings to e-learning is that students have "anytime-anywhere" access to course material.

Much research is now being carried out into providing services on these mobile devices for learning. The MOBIlearn project is a worldwide European-led research and development project exploring learning through a mobile environment (*www.mobilearn.org*). This project concentrates on creating pedagogy for learning in these environments, and looks at the adaptation of existing e-learning content for mobile devices. Their main objective is to enable content delivery for adult learning and professional development through collaborative spaces, context awareness, and adaptive human interfaces. M-learning is another European research and development programme that aims to deliver learning content to young adults who are no longer taking part in education or training (*www.m-learning.org*). In particular, they target those who are unemployed or homeless and those who do not enjoy traditional education. To engage the user in learning, themes of interest to young adults are used and are presented in the form of interactive quizzes and games. Modules include activities designed to develop aspects of literacy and numeracy. They have developed a number of learning tools ranging from interactive quizzes for teaching languages and driver theory test to giving the learners access to online Web page building and community tools.

Many researchers see games and interactive challenges as the way forward into mobile learning. Ketamo (2002) has designed a game for handheld devices that teaches geometry to 6-year-old kindergarten kids. The system proved effective and in particular helped low-skilled students understand geometry better. Göth, Hass, and Schwabe (2004) have developed a location-based game to help new university students become familiar with the university and its surroundings. Students are grouped into teams and have to carry out a number of tasks at certain locations on the campus. Pocket PiCoMap, as described in Luchini, Quintana, and Soloway (2003), is another interactive tool for mobile learning which helps students build concept maps (i.e., graphical representations of complex ideas and the relationships between them). Students draw a link between two concepts on their map and can then add a descriptive label to this linking edge. An English sentence describing the visual representation is dynamically created and displayed, thus helping the students understand how the relationship between the concepts is interpreted.

Some applications using 3D graphics on mobile devices are now also being developed offering a wide range of services to their users. For example, Lipman (2002) explored the use of 3D models on mobile devices for the visualisation of structural steelwork models on construction sites. Zimmerman, Barnes, and Leventhal (2003) designed an effective system for teaching mobile users the art of origami. A 3D model is provided showing the different steps involved in creating a particular shape. The user follows a set of instructions and uses the 3D model as a visual aid to gain a better understanding of the action they are to perform. This rendering of 3D graphics on mobile devices is an area of interest to us, and together with the potential of these devices to provide tools for collaboration, we feel a mobile learning system with these technologies could be very effective.

Above, we have outlined ways in which 3D graphics have been used for learning. Initially, 3D was used as a means of training within specific fields. For example, it proved popular for teaching medical students to perform surgery. More recently, 3D graphics have been amalgamated with multi-user technologies to form complete learning environments. A number of projects using this technology have been identified and discussed above. Within these environments, students take on the role of a character and navigate through a virtual on-screen location to access course notes and interact with each other. Each of the systems described have their own merits and limitations. Building on the strengths of the systems above and proposing a solution to their limitations, we have developed a system that recognises the importance of social learning as

part of an individual's education. This aspect was not fully addressed by other systems. Many of the traditional text-based e-learning systems discussed previously are aimed at third level students, providing diploma and degree qualifications. To date, no collaborative VR learning environment has been developed to solely cater to this particular market. Our research investigates the benefits that a 3D learning environment can bring to this domain. As the prevalence of mobile devices increases, their use as a learning tool is now being researched. Above, we have presented some currently available m-learning systems, and we too are exploring this area. In the next section we discuss our research, as we develop both a desktop 3D collaborative learning environment and a mobile application to supplement this. In particular, our system examines the use of 3D graphics in conjunction with various collaborative tools to act as a medium for learning.

COLLABORATIVE LEARNING ENVIRONMENT WITH VIRTUAL REALITY (CLEV-R)

The system which we are developing is entitled collaborative learning environment with virtual reality (CLEV-R) and addresses problems with current e-learning systems. The main objectives of the research underlying the development of CLEV-R include:

- Exploring the use of a 3D multi-user environment for e-learning, both to supplement traditional learning and for use in distance education.
- Supporting both social interaction and collaboration among system users.
- Developing the system so that it is cost-effective and requires minimal software on the client side.
- Exploring the extension of 3D interfaces for learning to mobile devices.
- Evaluating the resulting systems in terms of usability and effectiveness as a learning solution.

The following scenario indicates some issues faced by people wishing to take part in online courses. It highlights how a system like CLEV-R can address many of the concerns which people experience when using distance learning tools online.

Sample Scenario

Mary has been working for several years as an administrator in a legal firm. She wishes to further her career by obtaining a professional qualification. As she is working full time, she is unable to attend a university. Her employer suggests that she takes an online course. She has reservations about doing this because she knows of others who have found it difficult to complete courses online. They found them to be challenging; the lack of contact with others was isolating and it was difficult to maintain motivation for the duration of the course. Her friend Rachel recommends CLEV-R, an e-learning system that she found very convenient. She completed a business course using this system and said it was an enjoyable way to learn. Rachel attended university once a month; however, the rest of the course took place in a 3D virtual environment online. CLEV-R is also available on mobile devices and so she often used her PDA to access course content and communication tools while on the move. She particularly liked the collaborative aspects of CLEV-R and used them for both learning and socialising with others. Mary is convinced that this is an ideal solution for her learning needs.

The problem that Mary faced is a typical one, encountered by many people wishing to take up online courses. The social isolation, ennui, and lack of support within e-learning applications are all issues which we are addressing through the development of an online collaborative learning

environment that uses 3D graphics and VR to engage and motivate the user. Our VR environment for e-learning concentrates on providing collaborative tools so students can work, learn, and socialise together (Monahan, McArdle, Bertolotto, & Mangina, 2005). Mimicking a real university, it consists of a central common area surrounded by lecture rooms, meeting rooms, and social rooms. Learning materials are presented within the environment through various multimedia techniques and communication controls, such as text and audio chat, allow students and tutors to converse easily (Monahan, McArdle, & Bertolotto, 2005). The following paragraphs outline some of the most important features of the system and explain their use in an e-learning application.

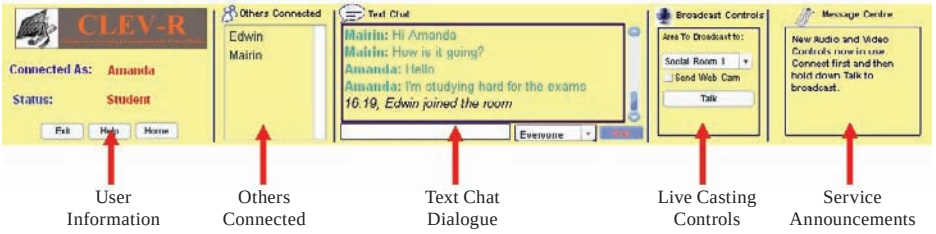
User Representation

One of the main disadvantages people see with existing e-learning applications is the lack of social presence and the feeling of isolation that can be experienced while partaking in an online course. Thus, one of the primary objectives of our environment is to remove this sense of loneliness and create a greater sense of community within each online course. The basis for our online collaborative learning environment is to facilitate multi-user support, allowing many users to be present and navigate around the same environment simultaneously. It is also vitally important that users of the environment are aware of all other connected users at any one point in time. Users are represented within the system by avatars. Upon registering for a course, each student and tutor is required to select a character to represent him or her in the VR environment. This 3D character is the user's on-screen persona for the duration of a course. In order to create an effective learning community, it is imperative that these avatars are distinctive for each individual user. In this way, avatar representations allow users of the system to recognize others, and hence feel a social presence in the learning environment. Applying different clothing or hairstyles to each character can create unique avatars.

Communication Tools

In order to support collaboration, communication technologies are imperative. In fact, it is the lack of support for real-time communication that we feel is a major drawback in current e-learning systems. In any learning scenario, it is imperative that students have a lot of communication with course tutors and also with their fellow students. Much research has been carried out to determine the importance of communication in learning, and it been has shown that students often learn from each other in informal chats as well as from lecture content (Redfern et al., 2002; Laister et al., 2002). Communicating with others who are partaking in the same course makes students feel more involved in the learning environment and removes any sense of isolation that may occur in single-user learning environments. As such, a major aspect of CLEV-R is the provision of multiple communication methods. The communication controls for CLEV-R are provided in a graphical user interface (GUI), as shown in Figure 6. Text and audio chat communication is supported. Students can send both public and private messages via text-chat and can broadcast audio streams into specific areas of the VR environment. Also users may broadcast Web-cams into the 3D environment and so have real-time face-to-face conversations with other connected users. The avatars in our system are enabled with gesture animations, which are a further form of communication. For example, avatars can raise their hand if they wish to ask a question and can also nod or shake their head to show their level of understanding of a certain topic. Of course users can also communicate asynchronously with others via e-mail.

Figure 6. The communication controls of CLEV-R



Interactive Tools

Another common problem with Web-based learning environments is that the learning content is primarily presented through various forms of text, including word files, PDF documents, HTML, and so forth. While these may be effective for presenting the learning material, they do not portray course content in a motivating or engaging way for the students. Thus, within the development of CLEV-R, we provide different multimedia methods for presenting course content within the learning environment. The system supports features such as PowerPoint slides, movies, audio, animations, and images. Rather than downloading these media files to the students' own PC, they can be experienced from within the virtual environment in real-time with other students. Many different features are available within the various virtual rooms of CLEV-R to support these file types. These are outlined in Figure 7, and the remainder of this section describes the different areas in our virtual university and the support for learning that each provides.

Lecture Room

The lecture room is the virtual space where most of the tutor-led synchronous learning occurs, and it supports a learning style similar to traditional

Figure 7. Virtual university structure within CLEV-R

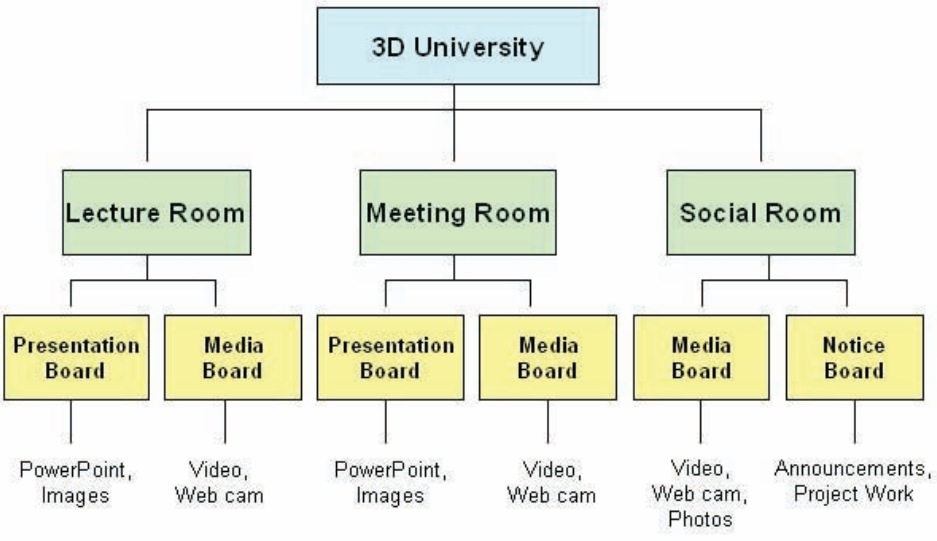


Figure 8. An online lecture taking place within CLEV-R

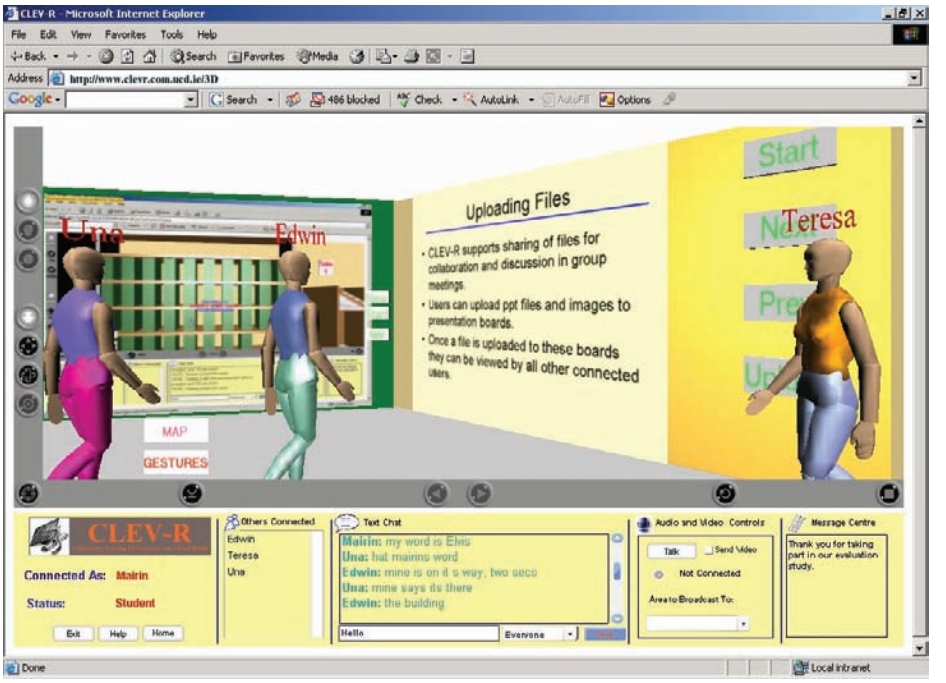
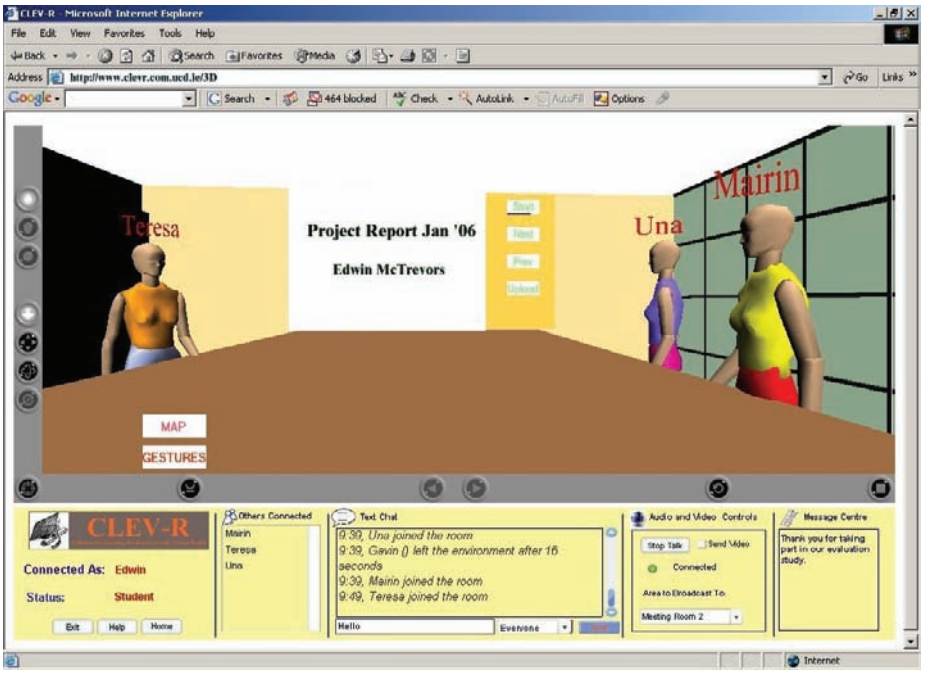


classroom-based education. This room provides several features to enable a tutor to present learning material to a number of students simultaneously. An example of an online lecture can be seen in Figure 8. A media board is provided, where the lecturer can upload both audio and video files. Where appropriate, the lecturer also has the option of streaming live Web-cam feeds into the lecture room. This can be used for demonstrating more practical aspects of a course or as a video conferencing tool for guest speakers. Lecture slides, such as PowerPoint files, can be displayed on a presentation board, which also supports images files, including GIFs, JPGs, and PNGs. The tutor controls this presentation board and can progress through slide shows displayed here. Once the tutor changes the current slide, it is changed in the worlds of all connected students. In this way, students are continually kept up-to date about the state of the environment and are always aware what learning content is currently displayed. The tutor can also use the streaming audio facility to provide live audio commentary to accompany the presentation and address any questions raised by students.

Meeting Rooms

As one of the main focuses of CLEV-R is collaboration, it is very important to provide an area for this collaboration to take place. While the entire environment can be used for collaboration, designated areas of the environment provide additional functionality for groups of students to meet and work together. The meeting room as shown in Figure 9 provides a similar set of tools found in the lecture room. Students can use audio and text messages to communicate their ideas with each other. A presentation board allows students to upload their own material to the room for discussion. Each student can bring slideshows, animations, and media clips for discussion and viewing by the entire group. Live video can also be streamed into this room via a student's Web-cam to aid with the discussion.

Figure 9. Media board displaying a video within CLEV-R



Social Rooms

Social interaction is a key component of CLEV-R, and therefore nominated areas of the 3D university have been specifically created for users to mingle and partake in informal conversation with each other. While students can use these areas to discuss the course they are attending, they can also use them for social purposes. In a similar way to the meeting rooms, small numbers of students can gather together to share their experiences and stories as well as photos, pictures, and movies. Social rooms exist where a media board is available for students to upload images, videos, and Web-cam broadcasts. A centrally located lobby also serves as an informal setting, where students can chat and build rapports with others. Here users can talk informally about the course material. Students can display their project work on special notice boards provided; others can then peruse these posters at their own pace and in their own time. Students can also place advertisements for upcoming events and other general notices in this common area.

Library

As CLEV-R is primarily a learning environment, it provides easy access to learning material through a library. The library contains a bookcase and a number of desks. Lecture notes, which have been uploaded to the lecture room by the tutor, are automatically represented in the form of a book in the bookcase. When a student clicks on one of the books, the lecture notes associated with that book are displayed on a desk in the library. The student can then peruse the notes in situ within the 3D environment or download them to their own computer. The bookcase in the library also contains a number of links to external information sources such as online dictionaries and encyclopaedias.

Evaluation and Discussion

A usability study has been conducted to obtain user feedback on the CLEV-R system and also to ensure the standard of the functionality was adequate for users' needs. The test subjects took on the role of students within the 3D environment. They consisted of 7 postgraduate students, one secondary school teacher, and one college lecturer. The user trial was set up to ensure each user was exposed to all the features of CLEV-R. The test subjects registered for the system and choose an avatar to represent them in the 3D environment. Prior to the trial, each test subject received an image and a PowerPoint file via e-mail. They were also supplied with instructions for completing the user trial and an evaluation sheet. At an appointed time, those taking part in the trail attended a synchronous lecture in which a tutor presented slides and gave instructions on how to use CLEV-R. After a short class, the students were asked to complete a set of tasks, which involved exploring the 3D environment and the features it provides. For example, they were asked to access a set of notes from the library, view them, and download them to their own computer. Other tasks included uploading the supplied image. The participants were also required to test the text and audio communication features. Toward the end of the trial, all test subjects were instructed to attend a virtual meeting room where they had to upload their PowerPoint slides and discuss them. By assigning tasks in this way, each student experienced the facilities provided in CLEV-R and was able to supply feedback on both usability and the usefulness of the system for learning.

The results were encouraging and all test subjects were enthusiastic about the system.

As intuitive navigation within the 3D environment is a key aspect of the system, we were particularly interested in user-feedback on this matter. The feedback relating to navigation was mixed. While those who had prior experience of using 3D environments found manoeuvring easy, it took novice users some time to become familiar with the controls. Entering rooms proved particularly difficult and so we are improving the situation by removing doors and making the doorways wider. Test subjects found the communication controls easy to use, although some experienced an echo while using the audio controls. This can occur if speakers are too close in proximity to the microphone and so clearer instructions on this could resolve this issue. The lecture room was seen as an effective medium for teaching, and the participants particularly liked the real-time communication features. All users successfully uploaded files to the CLEV-R environment and collaborated on a task. Another key area of interest to us during this evaluation was the users' sense of immersion and presence within the 3D learning environment. Most of the test users felt part of a group and no one felt isolated during the evaluation. All of the subjects were engaged in the interactive environment and their interest in learning was maintained throughout the trial.

Test users with previous experience of e-learning systems were asked to comment further on CLEV-R, comparing its features to the e-learning systems previously encountered. The collaborative features of CLEV-R proved popular with these test subjects and they also liked their awareness of others during the online session. This is a feature they found lacking in other e-learning systems. Since the user trial, we have begun to address some of the technical issues that arose. We are also using the comments and feedback from the test subjects to improve the set of features CLEV-R provides. This preliminary user-trial paves the way for a more extensive trial with a larger number of test users in the near future.

mCLEV-R

We are developing a mobile version of CLEV-R that will provide "anytime-anywhere" access to learning resources. This mobile version is called mCLEV-R and provides the opportunity for people

on the move to work through course material and to communicate with course tutors and other users in real time when they cannot be stationed at a fixed location. Our research in this field has focused on the following aspects:

- Exploring the use of a 3D interface for m-learning.
- Examining the technical capabilities of small mobile devices with regard to 3D graphics. In particular, we are exploring the use of the Virtual Reality Modelling Language (VRML) on personal digital assistants (PDAs).
- Facilitating the use of PDAs as a collaboration tool for e-learning.
- Evaluating this ubiquitous and pervasive system for learning.

Mobile devices have certain limitations when it comes to developing any application for them. Small screen sizes with low resolution make it difficult to ensure an application looks well and displays all necessary information. Limited memory for running applications, and also for storage, means applications need to be light weight. Also, lack of software support is another concern. Their inexpensive and convenient nature, however, makes them the ideal target for a learning application, and once mCLEV-R has been developed, we feel it will be of great benefit to any mobile student.

Due to the device limitations mentioned above, the system needs to be greatly modified for this new platform. Firstly, the 3D environment provided in mCLEV-R is much simpler than that of the full-scale system. Only features absolutely necessary are downloaded to mobile devices, and even then may need to be simplified for more efficient rendering. For example, textures can be replaced with simple colours and complex shapes can be simplified or removed altogether depending on their importance in the environment. It is also necessary to reduce the functionality for the mobile system. Thus, we must prioritise the features of the system, carefully selecting those best suited to a mobile platform. The two most important features of our system are firstly to present learning content to users, and secondly to support social interaction among connected users. Thus mCLEV-R supports both these features.

Access to course content is supported through synchronisation with a desktop PC and by download from the 3D interface on the mobile device

Figure 10. The mCLEV-R interface on PDA

(see Figure 10). Due to small screen size and low resolution of the PDAs, course notes cannot be displayed clearly within the 3D environment. Therefore, we use external applications such as Pocket Word, Pocket Slideshow, and Pocket Adobe Acrobat Reader to open course files on these devices. Technological limitations of these devices, including lack of software support, mean it is unfortunately not possible to ensure full consistency with the desktop version of CLEV-R. Thus students on mobile devices are not aware when a tutor changes a lecture slide and are not updated about other users' locations in the environment. They can, however, be notified about important changes in the environment through the communication techniques provided. Both text chat, as seen in Figure 7, and audio chat are available in the mobile system. Thus, mCLEV-R users are continually aware of other connected users and can converse via these communication modes in real time, making them feel part of the learning community.

We have introduced our system, CLEV-R, a collaborative learning environment with virtual reality that is used for e-learning. It takes a novel and modern approach to address some of the issues and problems with existing e-learning systems. A 3D university is provided where students can learn together with learning material delivered through the medium of VR. Online lectures are enhanced through the addition of multimedia, animations, and live video. These enhancements help to stimulate and motivate students. Recognising the importance of social learning, CLEV-R provides a social setting where students can interact with one another. Collaboration on group and project work is also possible using designated areas and special tools within the environment. CLEV-R promises to improve the usability of online learning and enhance the students' learning experience. The extension of the system to mobile devices is highly innovative and presents interesting research challenges. A subset of the functionality is provided on PDAs, and we feel mCLEV-R will be an invaluable accompaniment to the full-scale system, giving students the opportunities an ubiquitous learning environment provides. Once development is complete, we look forward to the results of an extensive evaluation determining their true value for online learning.

FUTURE TRENDS FOR COLLABORATIVE LEARNING ENVIRONMENTS WITH VIRTUAL REALITY

The e-learning domain is set to increase, as the focus in society shifts to life-long learning. People of all ages are now partaking in education courses, older generations are returning to the classroom to learn new skill sets, and younger generations are staying in education longer. E-learning is an ideal solution for the needs of life-long learning, allowing people to access course content, material, and help where and when they want. There is thus no doubt that research into the provision of e-learning courses will continue well into the future. But what exactly does the future have in store for e-learning?

Throughout this chapter, we have examined the use of collaborative virtual reality environments for online learning. 3D interfaces like this are already being developed in other domains, such as e-commerce and tourism, and we see them becoming much more widespread in the future. 3D environments for online education are very effective, as they are stimulating and motivating and so engage the student in their learning. They are made all the more amenable and inviting when combined with the multi-user and collaborative features discussed above. As more of these systems emerge, the advantages (such as better retention rates for online courses and more interaction, discussion, and cooperation between students) will be seen by educators. We feel this will ultimately lead to a general accep-

tance of VR and 3D as a medium for learning. Of course, it would be naïve for us to think that this concludes research into e-learning. E-learning and distance learning are continually evolving, adapting to new technologies and new requirements. We have no doubt that this will continue in the future and so, based on current state of the art technologies, we now surmise what the next milestones in e-learning will be.

There is great potential within these 3D learning environments to further enhance a user's learning experience. Firstly, the environment could be personalised to each user's individual preferences, thus making the environment even more welcoming to them. Personalisation and adaptive user interfaces are areas of high interest at the moment (Liu, Wong, & Hui, 2003; Ye & Herbert, 2004) and they could also be applied to these 3D learning environments. These techniques examine user profiles and preferences, and subsequently adjust system features for each user accordingly. Therefore, a user could alter the physical appearance of the virtual world and state how they wish course notes to be displayed, what format they want them to be in for download, whether they want them to appear online to other users, and so forth. Software agents could also be added to the system to remove some mundane tasks for the user and oversee the management of the environment (McArdle, Monahan, Bertolotto, & Mangina, 2005). They could be used to make recommendations to the users about course material and other similar users, and indeed to help tutors keep track of students' progress and results.

While the use of VR on desktop computers continues to grow in popularity, research is now being carried out on the possible uses of augmented reality (AR). This branch of computer science is concerned with augmenting a real world environment or scene with computer-generated objects. This is often achieved through the use of head mounted displays (HMDs); the user wears a special pair of glasses and as they look at objects in the real world, computer generated 3D objects and data are superimposed into their view via the glasses. While AR research has been taking place for some time, it is only now that hardware is able to deliver results which are satisfactory to the user. One of the driving forces behind this technology is the area of medical visualisation. An example of a system using a HMD to project a 3D model of a patient's liver is described by Bornik, Beichel, Reitinger, Sorantin, Werkgartner, Leberl, et al. (2003). This tool renders the patient's liver from an x-ray computed tomography (CT) scan and enables surgeons to measure the dimensions of the liver to locate a tumour prior to surgery. The surgeon can then manipulate this model to obtain different viewing angles and see features in more detail. One drawback of using head mounted displays is that they tend to be cumbersome to wear and do not feel very natural. Again, it is in the medical visualisation arena in which strides are being made to alleviate this issue. Schnaider, Schwald, Seibert, and Weller (2003) have developed MEDARPA, a tool to assist with minimal invasive surgery. It consists of the practitioner looking through a screen, which is placed over the patient. Based on information from previous scans, an internal view of the patient is displayed on the screen; sensors track the position of the screen and the doctor's tools and update the image accordingly. The doctor can then use the on screen image as a guide for the keyhole surgery.

These two examples from within the medical domain show where this technology is heading. As mentioned earlier, distance learning and learning in general, has always evolved with technology and there is no reason why it will not embrace this new AR technology. One can easily see how this technology could be adapted for education. The very fact that 3D models themselves can be projected into the real world provide a means for students to see for themselves things that may have been dealt with in a theoretical way within

the traditional classroom. For example, complex chemical structures, human organs, computer components, and sophisticated machinery can be projected into the real world for students to interact with and manipulate, therefore increasing their understanding of a topic. We see the future of collaborative learning environments as discussed above adapting to augmented reality. A student, or indeed a teacher who is not able to attend the physical classroom setting, may have their representation projected into the classroom. They can then see the lecture taking place, and others are aware of their presence and can interact with them in a natural way. An alternative to this idea is for a holographic representation of the teacher to be projected to the location where the remote student is, in a similar style to that seen in the Star Wars movie series. Unfortunately, acceptance and widespread availability of this form of technology is a long way off.

Before the advent of AR technologies that offer truly ubiquitous and pervasive learning environments, the use of mobile computers as a supplement to e-learning will increase. As people lead busier and more hectic lives, the need to access learning content while on the move will become paramount, and m-learning will emerge as a solution to this. We envisage great improvements in mobile technologies that will allow people to access vast amounts of learning content from PDAs and mobile phones in the future. Improvements and growth in wireless networks will allow more sophisticated communication and collaborative techniques, and will also make it possible for mobile users to download large detailed virtual environments and fully partake in synchronous and interactive learning scenarios like the one CLEV-R permits. Systems like ours, with its collaborative tools supporting interaction between students, will be particularly beneficial and will play an important role in moulding the future of m-learning.

CONCLUSION

This chapter gives a brief insight into the history of distance learning, outlining how it is continually evolving and adapting to new technologies, and arguing that e-learning will embrace the current range of VR technologies now available. We particularly focus on the need for collaboration within e-learning systems. This chapter shows how 3D graphics, with its roots as a modelling tool for engineers, has been used in the past for computer games, and outlines how it is being used today in activities such as urban planning, tourism, and e-commerce. Online collaboration tools initially grew out of text-based fantasy computer games, and this chapter charts how they evolved, becoming conference tools and later acting as social aids. The use of 3D, combined with collaboration techniques, is a more recent phenomenon and several examples of such systems being developed have been discussed. These systems offer a new form of e-learning, addressing many of the issues, such as isolation and lack of motivation, which students often experience while using text-based e-learning environments. The benefits and weaknesses of these new VR e-learning systems are presented.

This chapter describes our efforts in developing a VR e-learning system called CLEV-R. Like some of the other systems, CLEV-R has the remit of providing a motivating and stimulating multi-user 3D environment; however, our research recognises the importance of social learning within groups of students, and so offers specific features to facilitate this. CLEV-R is an intuitive, multimedia rich Web-based environment, which can be used both as a complete distance learning solution and as an accompaniment to traditional classroom-based teaching. Unlike the other systems presented in this chapter, CLEV-R uniquely offers support for providing learning material and collaboration tools on mobile devices, such as

PDAs. This addition provides anytime, anywhere access to course material and allows students to interact while they are away from their desktop computer. The use of mobile devices is a new avenue in the e-learning paradigm, which has recently been termed m-learning. As the need for pervasive learning environments comes to the forefront of the research community, the use of m-learning is sure to increase. We have also discussed some interesting future trends within 3D visualisations, particularly demonstrating how the need for improvements in medical visualisation is fuelling research in Augmented Reality. We conclude this chapter by proposing how AR can be adapted for use as a tool within e-learning to provide a truly pervasive and ubiquitous learning environment.

APPENDIX I: INTERNET SESSION

C-VISions: Collaborative Virtual Interactive Simulations

The C-VISions research group develop interactive simulations to help students learn (*http://yamsanchee.myplace.nie.edu.sg/NUSprojects/cvisions/cvisions.htm*). The Web site above provides details of their work along with relevant publications. Use this information to prepare a presentation, outlining the background to the research along with a synopsis of the systems they have developed.

APPENDIX II: CASE STUDY

A university has been offering a virtual reality learning environment as an accompaniment to classes and as a distance learning solution for three years now. Students' acceptance of the technology has been high; however, faculty have been slow to adopt this new method of teaching.

Comp 4015 is a software engineering module offered by the university. The course involves the tutor giving a number of lectures detailing best practice methods for Java Programming; this generally takes the form of a PowerPoint presentation showing examples of poor coding. The tutor then asks individual pupils how they would fix the problem. This creates interaction and discussion within the class. Another aspect of the Comp 4015 module involves students working together on a group project, where each team must design a program to address a fictional company's needs. At the end of the course they must present their work to the class. The tutor is very reluctant to offer this course via the virtual reality environment. He feels the dialog in which the students engage in during the actual lectures will be lost. He is particularly worried that the group project will no longer be possible and it may have to become a project for individual students instead. Thirty percent of a student's final grade for this module comes from the final presentation, which students give, and the tutor is concerned that the student's presentations will no longer be possible if the module is offered via the virtual environment.

Taking the CLEV-R system described above, encourage the tutor to offer the Comp 4015 module in the virtual environment by offering advice on the following points and questions raised by the tutor:

1. The tutor has been teaching this module for many years and has all the lecture slides and material ready. He does not want to change the material in order to tailor it for the virtual environment.
2. How can the interaction, which his classes are well known for, be maintained when the module is offered in the virtual reality environment?
3. Can people who may never meet really partake in a group project and give a presentation at the end? What tools support this?
4. Students will just be anonymous, with no personality and no way for them to be distinguished or to get to know each other. Is there any way to address this?
5. Suggest how mCLEV-R, the mobile accompaniment to CLEV-R could be introduced and used on this course.

Chapter 5.11
Empirical Validation of a Multimedia Construct for Learning

Paul Kawachi
Kurume Shin-Ai Women's College, Japan

ABSTRACT

A multimedia construct for learning based on the Theory of Transactional Distance has been developed consisting of four stages of decreasing transactional distance. This model has been applied in various teaching and learning contexts, on- and off-line, and its validation was investigated. Results confirmed in practice the four distinct sequential stages. Difficulties were discovered in navigating through the collaborative second and third stages, consistent with findings from related studies on acquiring critical thinking skills. Specific areas for attention were identified to promote learning using multimedia.

INTRODUCTION

Previous Models of Learning

Two significant models have been proposed to identify the essential steps of learning critical-thinking skills: one by Dewey (1933) and another by Brookfield (1987). Dewey proposed five phases of reflective or critical thinking:

1. Suggestions, in which the mind leaps forward to a possible solution
2. An intellectualization of the difficulty or perplexity that has been felt (directly experienced) into a problem to be solved, a question for which the answer must be sought
3. The use of one suggestion after another as a leading idea, or hypothesis, to initiate and guide observation and other operations in collection of factual material
4. The mental elaboration of the idea or supposition (reasoning, in the sense in which reasoning is a part, not the whole, of inference)
5. Testing the hypothesis by overt or imaginative action

Brookfield also proposed five phases to develop critical thinking:

1. A triggering event
2. An appraisal of the situation
3. An exploration to explain anomalies or discrepancies
4. Developing alternative perspectives
5. Integration of alternatives in ways of thinking or living

However, the steps given in the above models do not correlate with each other. The steps are not clearly distinguishable, and the actual process need not be sequenced linearly. So these models are not sufficiently clear to constitute the basis of a syllabus. A new clear and practical model is proposed based on the distinct ways of learning. And this new model will constitute the basis for an intelligent syllabus for acquiring critical-thinking skills using multimedia.

The Distinct Ways of Learning

There are four distinct ways of learning (Kawachi, 2003a): learning alone independently, alone individually, in a group cooperatively, and in a group collaboratively. Here it is important to distinguish cooperative learning from collaborative learning, in order to deploy these in the new model detailed below.

Cooperative learning essentially involves at least one member of the group who "knows" the content soon to be learned by the other(s). Learning takes place through the "knower" repeating, reiterating, recapitulating, paraphrasing, summarizing, reorganizing, or translating the point to be learned.

Collaborative learning follows a scientific process of testing out hypotheses. A participant publicly articulates his (or her) own opinion as a hypothesis, and being open to the value of conflict allows this to be negated if possible by others, in which case the original participant or another offers up a modified or alternative hypothesis for public scrutiny. In collaborative learning, disagreement and intellectual conflict are desirable interactions. All participants share in coconstructing the new knowledge together, and this learning occurs inside the group as a type of consensus achieved through analysis and argument. In collaborative learning, there was no "knower" prior to the learning process taking place (in contrast to the situation of cooperative learning).

Need for a New Model of Learning

Largely as a result of the rapid expansion of open and distance education, learning theory has undergone a revolution to a social constructivist paradigm based on cognitive concepts of how we learn. Previous models of learning have been too vague for applying to current learning practices through computer-mediated communications. Hence, there is a need for a new practical model.

NEW MULTIMEDIA LEARNING MODEL

A new model for learning critical thinking using multimedia has been proposed by Kawachi (2003b). Design is a key characteristic generally lacking in the current applications to date of computer-mediated communications adopted in conventional face-to-face or distance education courses. The presented Design for Multimedia in Learning (DML) model translates conventional theoretical models of learning into an efficient practical design for use in the multimedia educational environment. While the two leading previous models have variously postulated five phases to critical thinking for learning, this new model has four distinct stages, and is directly underpinned by Moore's (1993) Theory of Transactional Distance. This theory, which involves educative-dialogue (D), prescribed structure (S), and student autonomy (A), tries to measure the psychological distance between the student and the information

to be learned, and has been widely accepted as an effective theory underlying and informing open and distance education. The original theory only deals with one student, learning content with the interactions of a tutor. So it is adapted here to bring into account the important interactions among the student and other students (for a discussion here, see Kawachi, 2003b).

The four stages of the new DML model are as follows:

- In **Stage 1**, learning occurs in a group cooperatively, gathering and sharing information and fostering a learning community. Here synchronous-mode computer-mediated communications are best, such as chat and conferencing. However, it should not be forgotten that bridging telephony can simultaneously link 50 students synchronously with the tutor(s). Videorecording the interactions here could provide material for reflection in Stage 2, or as is often the case, the tutor as observer could take written notes for later distribution as a summary or transcription to the participants. This stage can be characterized by self-introductions (as a prelude to being a source of content material to other students), brainstorming (limited at Stage 1 to only accumulating new ideas, yet to be argued in Stage 2), involving divergent thinking to gather various different perceptions in order to explore and to frame each student's context, and helping each other as equals with obtaining content, especially in sharing personal experiences and past literature that has been read, which constitute old foundational knowledge. (Brainstorming is initiated by providing an ill-defined scenario or case study to elicit multiple perspectives.) The transactional distance initially is at a maximum (D- S-) with no teaching-dialogue and with no pre-set structure.
- In **Stage 2**, lateral-thinking (creative thinking around the problem) is used to generate and develop metaphors (an idea or conception that is basically dissimilar but formed from noting similarities between the initial information and the new concept) or new ideas, and these supported by argument. Students discuss, for example, their own problems that they have found which have brought them to participate in the current course, and then argue to identify possible solutions to each other's problems. Creative thinking here may derive from combining seemingly disparate parts, especially ideas contributed from others in different contexts into a new synergic whole. The teacher is still keeping academically at a distance away from the content under discussion, while the students are making their efforts to achieve some pre-set goals (to present own problem and reasons for engaging the current course, for example), which gives structure to their discussions (D- S+). Some time is needed for reflection here, and asynchronous modes such as e-mail and a bulletin board are effective because of the time interval incurrent between receiving the stimulus and the student's response. Moreover, these modes of interaction through written text also provide a written record to the student that enables recapitulation, retrieval of a theme, and recovery of someone's perspective, and so foster reflection.
- In **Stage 3**, the tutor engages the students with guiding comments in what Holmberg (1983) has described as a Guided Didactic Conversation, helping the students achieve the course structural requirements of understanding the general concepts to be learned (D+ S+). The tutor poses questions, and students defend their formulations. This stage is characterized by hypotheses testing and logical straightforward thinking (termed "vertical" thinking in contrast to "lateral" thinking) associated with problem solving and is collaborative. Problem-based learn-

ing can involve holding multiple alternative hypotheses at the same time, and evidence gathered can be assigned to examine simultaneously the various hypotheses. Asynchronous mode is ideal here, to allow sufficient time for cognitive connections and co-construction of new nonfoundational knowledge.

- In **Stage 4**, the final stage, the course requirements have largely been already achieved and there is no structure left, except to disseminate the achieved mental ideas and test them out in real life. This stage is characterized by experiential learning and is cooperative, and at minimum transactional distance (D+ S-), in synchronous mode, and with teaching dialogue to assist the students to reflect on their studies.

STUDENT AUTONOMY IN LEARNING

Definitions of "autonomy" in learning have in common an emphasis on the capacity to think rationally, reflect, analyze evidence, and make judgments; to know oneself and be free to form and express one's own opinions; and finally, to be able to act in the world (Tennant & Pogson, 1995). These qualities characterize the collaborative thought processes of Stage 3, and also the experiential aspect of Stage 4. Stage 1 has maximal transactional distance, and for a student to succeed here in independent learning, Moore (1993) pointed out that the student would need maximum autonomy (p. 27). Autonomy is thus seen as a highly powerful and desirable quality for independent learners. Not all students bring this high level of autonomy with them initially into their studies, and so the tutor must bring the student around to acquire this autonomy. The DML model illustrates a cyclical process—even an iterative process—through Stages 1 to 4 to equip and bring the student to go onto independent learning in a further new cycle starting at Stage 1 in a new learning venture.

Autonomy has also been related to recognizing one's interdependence on others (Boud, 1988). Interdependence relates to understanding the need to learn together with others, either in cooperative mode or at other times in collaborative. Interdependence is a maturity characterizing an adult student and is acquired through awareness and prior experience of the critical-thinking process. Toward the end of Stage 4, the student can have acquired this sense of interdependence. So in entering a new Stage 1 interaction, the student may be interdependent (post-Stage 4) and once more newly independent (starting a fresh Stage 1). These attributes of independence and interdependence have already been found to be separate, orthogonal, and coexisting in mature students at the end of their course (Chen & Willits, 1999).

While autonomy is defined as an attribute of the student, different distance education programs and the different stages in the DML model relate to different levels of autonomy for the student to be a successful learner. In a program at Stage 2, the deployed structure means that the student is charged with thinking rationally, but horizontally rather than vertically, and is analyzing already-given evidence, rather than finding new evidence, so the quality of autonomy is somewhat measured to fit the limited freedom given to the student. At Stage 3, different qualities of autonomy for hypotheses testing are needed for success—including a mature openness to new ideas that might be in conflict with one's previous and present conceived view of the world. The student needs to exercise the freedom to formulate or reformulate one's own conceptions. While in Stage 4, the quality of autonomy should include the willingness and ability to act to test out these newly constructed ideas to see experientially how they operate in practice.

It is difficult, therefore, and moreover unhelpful to assign an integrated level of autonomy to each stage in the DML model. The student should utilize

measured amounts of the various qualities that constitute autonomy during each stage to support learning. Can the tutor and institution influence the level and qualities of autonomy used by the student? Yes. And explicit clear advice from the tutor may be all that is required. The student, however, might not yet possess the skills for exercising the full range of qualities constituting autonomy (in other words, is unequipped for full autonomy). The novice and nonexpert will likely need scaffolding help at different stages to cope.

SCAFFOLDING FOR LEARNING

Scaffolding is the intervention of a tutor in a process that enables the student to solve a problem, carry out a task, or achieve a goal that would be beyond the student's unassisted efforts (Wood et al., 1976, p. 190). In providing individualized scaffolding, the tutor knows the intended knowledge to be learned and has a fair grasp of the prospective development for the student. The distance between the unassisted level of capability and the potential level that can be achieved through scaffolding is Vygotsky's (1978) "zone of proximal development" (p.86). Vygotsky included the opportunity that such scaffolding could be from "more capable" other students, indicating a cooperative assistance (as opposed to a collaborative process). Wood et al. (1976) made this very clear: tutoring is "the means whereby an adult or 'expert' helps somebody who is less adult or less expert. …a situation in which one member 'knows the answer' and the other does not" (p. 89). Accordingly, we might be advised to reserve the term "tutor" for the cooperative Stages 1 and 4 only, and use a term "facilitator" for the collaborative processes of Stages 2 and 3.

In Stage 1, tutor intervention providing scaffolding includes making the outcomes of studying explicit to the student and ensuring that the student can comprehend the aims and objectives. If not, then tutor feedback and error correction become merely vehicles of information for imitation and copying, and vaporize these opportunities to acquire mastery. The tutor need not exercise full control over the discovery process. It is recognized that students also acquire learning through unexpected accidental discovery of knowledge.

Both Stage 2 (D- S+) and Stage 3 (D+ S+) are characterized by added structure.

In Stage 3, scaffolding should add a safe structure for the interactions involved in the analytic argumentation of hypotheses testing, which have led to some students feeling wounded, by so-called flaming. Zimmer (1995) proposed an effective framework involving three functional turn-taking steps ABA between two persons A and B, which when repeated as BAB give both participants the opportunities to give opinions and receive counteropinions empathetically, as follows:

A) (Hello) Affirm + Elicitation
B) Opinion + Request understanding
A) Confirm + Counteropinion
B) Affirm + Elicitation
A) Opinion + Request understanding
B) Confirm + Counteropinion

I should also like to propose another framework drawn from some ideas of Probst (1987) for collaborative learning in literature and art, in which transactions are not aimed at hypotheses-testing characterized by counteropinion but rather a new insight built on critical reflection that while shared may be personalized in each individual. In literature, learning is not cooperative: there is no "knower"; the tutor does not guide the student to some pre-set conclusion of the meaning of the text. In literature, the tutor or any student (A) elicits opinion to initiate the three functional turn-taking steps BAB (followed by ABA), as follows:

A) (Hello) Affirm + Elicitation
B) Opinion/Analysis + Request understanding
A) Affirm + Elicitation of evidence

B) Reflect + Elicit other opinions/Analyses

A) Opinion/Analysis + Request understanding
B) Affirm + Elicitation of evidence
A) Reflect + Elicit other opinions/Analyses

This framework—basically of reflective analysis followed by articulation, bring in ideas from their own reading or those elicited from other students, then repeat reflective analysis with accommodation to construct a new insight—involves the same cognitive processes that occur in individual learning. In the group, content comes from texts and other students, while in individual learning, content comes only from texts. In both cases, it is the transactions between the student and the content that creates the new knowledge in the student.

Courses based on experiential learning that focus on Stage 4 in synchronous mode can also benefit from explicit scaffolding. In non-face-to-face (nonvideo, nonaudio) synchronous "chat" text-based conferencing, students should be directed to articulate their feelings explicitly. Neubauer (2003a) found that once students had become skilled in explicitly stating their feelings (such as "I am confused…"), then their learning improved by better sharing experiences, and they then more highly valued their text-based content—more than if they had used visual face-to-face cues. So, scaffolding can also assist in Stage 4 synchronous chat experiential learning.

ON THE NUMBER OF PARTICIPANTS

In both the above frameworks, I suggest that any participant(s) may be behind either voice, so the framework could be effective for more than two persons at the same time. Bork (2001) has suggested that the optimal number may be four in collaborative transactions, in an optimal online class size of 20 students, while six has been reported by Laurillard (2002), and about 10 by others. Wang (2002) has asserted that engaging as many participants as possible would maximize diversity and optimize collaborative learning. Zimmer (1995) has found that provided participants are aware of the framework, then collaborative learning succeeded in practice for a group of 12 students.

The optimum number of active participants in synchronous cooperative learning is different from that for asynchronous collaborative learning. An online survey of those on the DEOS-L listserv, who have had relevant experience in conducting synchronous chat (Neubauer, 2003b), found the optimum number was from 10 to 20 students: if students were new to the synchronous media, then five to seven students was optimum; in groups of 10 to 15 mixed-experience students, then 10 was optimum; while if students were experienced and the moderator (tutor) also was experienced, then 15 was optimum. And the upper limit of 20 students was suggested to keep the discussion at a sufficiently fast rate to maintain high interest levels. There seemed to be a marked difference between respondents who found that five to seven was optimum and those who found that 20 was optimum, and this difference might be related to the task at hand. Five to seven new students would imply that they were at Stage 1, forming a learning community with personal introductions and so on, while 20 students were likely at Stage 4, sharing course experiences. A note should be added here to the effect that non-native-speakers of English might be slower and more apprehensive (than native speakers) about their actively participating in synchronous discussions (see, for example, Briguglio, 2000; Kawachi, 2000). That these synchronous discussions are cooperative and not collaborative, however, should mean that their state anxiety should be lower and performance higher than if collaborative discussion were conducted synchronously.

USING A FRAMEWORK

These two frameworks illustrate and scaffold the interactions, either synchronous or asynchronous, for learning collaboratively in a group. The framework indicates what content should optimally be included in an utterance, and specifies in what serial order to progress towards achieving discovery and coconstruction of new understanding and new knowledge. It should also be noted that the use of a framework also implies some timeliness in replies. The system would not function if turn-taking were violated or not forthcoming. Participants need to take responsibility for the group succeeding by actively providing what is required and when it is required. In this way, some pacing is inevitable if the group is to move towards achieving its goal.

To some large extent, nonresponse in an asynchronous environment can be overcome by others offering up the required content in time. This is often the case in synchronous free discussions. However, group cohesiveness depends on the active participation of all members of the group. If a student does not participate, the group is fragmented and not functioning as a whole. Prior to the task, coping strategies should be acquired, agreed upon, and then used when required, such as prearranging the time frame allowed within which a student should contribute, pairing up students to provide backup in case one is at a loss, or having the moderator provide behind-the-scenes coaxing and elicitation.

METHODOLOGY FOR VALIDATION OF THE MODEL

Research into preferred learning styles has suggested that while some students may be field-dependent, others are field-independent. Lyons et al. (1999) described how some are so-called right-brain dominant. These students tend to be intuitive and prefer informal unstructured learning environments and group discussions in empathetic elicitation, sharing, and valuing each other's experiences and views (who would prefer cooperative learning in a group). Others are so-called left-brain dominant and are analytic, rational, and objective (who would prefer collaborative learning in a group).

In order to validate the model empirically, hypertext linkages were added purposively into a Web-based course. The Internet is a nonnarrative media in which no predetermined pathway through it is provided to the student newly logging on. Hypertext linkages on corporate business Web sites have been categorized by Harrison (2002), but there has been no categorization to date of hypertext usage in educational Web sites. Here, some links were colored red to indicate that examples could be reached by clicking on the highlighted linkage, while other links were colored blue to indicate to the student specifically that reasons could be reached. The courseware was reduced in content by removing all preexisting or customary references to examples and reasons except for the colored hypertext links.

It was then postulated that during traveling through the courseware, some students preferred to see examples, while others preferred to see reasons, with both groups achieving learning of the general concepts with no significant difference in achieved quality of learning.

The students examined in this study were all Japanese, and Japanese students are known to prefer cooperative learning in a group and avoid critical evaluation of others, preferring instead to preserve group harmony through empathetic sharing (Kawachi, 2000).

By coloring each hypertext or telling the students directly what color it would be or which content could be reached through which link, it was then planned that students would not open a link simply from curiosity but would pass across any link they decided was not wanted and move onto opening a link that might be helpful in their accomplishing the task at hand. Students were

monitored in their selection. Students were also required to keep journals as a written "think-aloud" record for formative and summative evaluation. Students were also interviewed during and after their online studies. E-mail messages were also kept. Students were continually encouraged to interact with each other. This was to keep the group on task cohesively, providing peer support and pacing to some degree, as well as for the designed cooperative or collaborative interactions.

RESULTS

The above method for empirical validation of the DML model in Japan using specially designed hypertext courseware to investigate cooperative and collaborative pathways during learning was not entirely successful. The study found that students at the undergraduate level could successfully move through the first two stages but could not engage the third stage due to lack in sufficient foundational knowledge and experiential maturity. Interviews were conducted on the students, but these also failed to identify any cause for the breakdown in the learning cycle. Validation at the graduate and continuing adult education level is ongoing.

Course and Student Assessment

Summative records of achieved learning from each student indicated the particular stage reached by the student, and to a fair degree of accuracy, where within a stage was reached by the student. In each stage, indeed at any time throughout the course, interactions were recorded for formative and summative evaluations, of both the course itself and of the student's individual participation, contribution, learning process (including choices made), and quality of learning outcomes. In Stage 1, handwritten notes, audiorecording, or audio-video recording can serve these purposes. Only written reports, interviews, and tutor observations were used in the present study. In Stage 2 and Stage 3, the asynchronous modes are performed through written contributions, such as by mail, teletext, fax, or e-mail, so that records can be easily stored and retrieved. Nonacademic and academic exchanges between the student and others can usually be recorded (though recording telephone conversations needs informed consent). At the present time (June 2003), it remains technologically difficult, if not impossible, to record the hypertext-enabled learning narratives of each student. Some adaptive hypermedia can restrict the available hypertext choices, but at present, think-aloud, recall, and separate audio-video recording are the only means with which to track the pathways and learning processes of the students who were using interactive hypermedia. In the present study, the student journals, triangulated with interviews and observations, were used. Stage 4 is characterized by social constructivist experiential learning, which usually entails some form of public articulation of the student's tentative or summative perspective achieved from the previous stages. For example, a written thesis is the most common instrument of evaluation here. Oral presentation at a conference and publication of a report in an academic journal are also common instruments. In the present study, the final demonstration was different depending on the course. In all courses, there was a written summative report from each student. In one course, there was project work including a poster presentation and group journal thesis published. This thesis included individual reports of pathways and a group collective report.

In the empirical validation of the DML model in this study, the students were not paced, but the course was of predetermined duration. The aim at the outset was to bring all the students through all four stages to present some new personal meaning they had each achieved through the four-stage process. Observations and written records gathered during the course were revealing that many students were slower than expected—this

was even after the course was tailored to be at a comprehensible level fitting to each particular class. Within-class individual cognitive and affective differences were greater than expected. It thus transpired that the summative reports from the students, rather than confirming all had successfully completed the four stages, instead revealed the location within the model that they had each reached.

The small seminar class of six second-year undergraduates completed the four stages during the one year and adequately demonstrated their new socially constructed knowledge in an exhibition presentation, in a published journal, and in reflective reports of their experience and how the course had changed their thinking. The teaching aim was to scaffold and promote a desire in each of them for lifelong learning. Two of the six went on to engage in higher learning at another university.

Adult Motivations to Learn

In this validation study, student motivation to learn in a preferred way had a potential influence on the performance in certain stages. Therefore, to investigate any influence, students were surveyed by questionnaire on their preferred approaches to learning and their motivations. The questionnaires and self-reports were followed up by interviews. How to initiate each and all the various intrinsic motivations to learn has been previously reported by Kawachi (2002c). However, that study was based on the taxonomy of Gibbs et al. (1984), which used data from about 1960 which pre-date multimedia learning technologies. Briefly, there are the four intrinsic motivations: vocational, academic, personal, and social. These were discovered in the present study simultaneously in varying levels depending on the task and with individual differences. However, beyond these, there was suggested some motivation to lifelong learning that was difficult to accommodate within the nearest category of intrinsic personal challenge. This motivation was suggested by only the older postgraduate students. It is tentatively labeled the "aesthetic" motivation to learn. The discovery and illuminatory methodology used here was informed by various interview open responses leading into focused discussions, and it followed a grounded-theory approach. Two orthogonal dimensions were found and labeled as positive and negative incidences of *jouissance* occurring accidentally during the learning process. These incidences only occurred when the student was markedly actively learning—struggling to construct meaning to discover suddenly how things fit together in a shot of joy (positive *jouissance*) or how things had been mistaken and misunderstood (negative *jouissance*). This aesthetic motivation was concluded to be acting along the process of the interaction between the student and the content-to-be-learned (actually *to* the student *from* the content-to-be-learned, a unidirectional motivation). Aesthetic motivation derives *from* the process. There was a similar motivation acting in the opposite direction —*to* the process—of expressive motivation, in which the student is driven to proceed, by the joy of doing (as might occur for example in writing poetry, or fine-art painting). As an illustration, aesthetic motivation drives a hobby fisherman; positive *jouissance* occurs when the fisherman catches a surprisingly large fish, and alternatively, negative *jouissance* occurs when a fish escapes suddenly. Both these types occur only in the adult or mature person with an already fully formed self or culture, and they occur as a bursting of this bubble, momentarily and transiently. The fisherman's experience is increased by the *jouissance*, and he is more driven to continue fishing. Aesthetic motivation is the motivation to lifelong learning. The tutor needs to understand the limits of the student's context or worldview and guide the student to approach the limits of his or her world, hopefully to experience *jouissance* and initiate aesthetic motivation to learn.

Summary of Results

Repeated empirical studies found that only small classes with close tutor moderating, and preferably of students with sufficient background knowledge, could successfully engage the collaborative learning tasks and complete all four stages in this model. Most undergraduate students, especially in larger classes or even in small groups but with reduced tutor monitoring, could not engage the collaborative Stage 3. A similar finding was also reported by Perry (1970), in the United States, who concluded that college students were maybe not yet sufficiently mature to acquire the skills of critical thinking. It is well known (Kawachi, 2003c) that collaborative learning characterizes the construction of nonfoundational (graduate-level) knowledge rather than the acquisition of foundational knowledge (at the undergraduate level).

DISCUSSION

Scaffold Efficacy

The DML model was designed and intended to act as scaffolding to guide the teacher (in the present study, the author), inform the process, and assist student learning. It was not completely successful. This was due to the limited duration of the course and the levels of maturity in the students. The limited duration of the shorter (6-month) courses meant that the self-pacing or unpaced nature would not allow for the students to complete the full learning cycle. The low levels of maturity in the undergraduate younger students meant that they found much difficulty in navigating Stage 3.

Four separate modes of learning were serially linked in this DML model. Stage 1 employed synchronous media for cooperative brainstorming; Stage 2 employed asynchronous media for collaborative lateral thinking; Stage 3 employed asynchronous media for collaborative vertical thinking and problem-based learning; and Stage 4 employed synchronous media for experiential learning. This model indicates the need to change the type of media employed during the learning process, for example, from synchronous to asynchronous to move from Stage 1 to Stage 2. While Stage 3 proved difficult for some students, the largest hurdle was found in moving from asynchronous collaborative Stage 2 to asynchronous collaborative Stage 3. This needs to be discussed. The task activities of Stage 3 require the students to raise doubts about others, to question the teacher and the text, and to search for one's own opinion, even though this might be against the established opinions of others in authority. One reason for the students not moving into Stage 3 was that the activities of Stage 3 were inconsistent and incongruous with their own lives or cultural views of the world (for example, see Briguglio, 2000, p. 3, for a discussion of Jones, 1999, unpublished report).

These questioning skills may be characteristic of a mature adult. In support of this DML model to master these questioning skills of Stage 3, Halpern (1984) reported that all adults should learn to question input prior to acquisition, in what he described as a "content" effect: "When we reason we do not automatically accept the given premises as true. We use our knowledge about the topic (content) to judge the veracity of the premises and to supply additional information that influences which conclusion we will accept as valid" (p. 359). Adults generally have more experience than adolescents from which to draw additional information, so they can be expected to be more questioning during learning from a teacher or other resource. Younger or immature adults can be expected to not yet hold adequate foundational knowledge with which to engage the Stage 3 questioning and answering.

Moreover, a gender difference might be operating here. Raising doubts about others, and having others raise doubts about you, may be an undesirable activity for some students—not

only for women but also for those who may be disadvantaged by physical or mental dysfunctions and those who may not be adequately literate. There are many kinds of literacy involved here—linguistic literacy in a first language, linguistic literacy in the language as medium of the education (notably in English as a foreign language), information literacy (the capability to find information efficiently), cyber-literacy (the capability to handle virtual systems and manage oneself within these), and technological literacy (the capabilities to manage and interact through the human–computer interface). In such cases, the need for conservation of self may rise higher than the internal drive or need for progression through further education.

Women who try distance education may be more likely to bring with them higher levels of self-doubt and anxieties that can add a more cautious approach to their questioning of authorities. Also, traditionally, higher education has not been part of their world and self-concept, so they are operating in a somewhat alien world, and one that is not congruous with their present conception of the world. This may also be true for men, because adults generally have already established their social world and self, and where this does not include higher education—as in those who engage in higher education for the first time as a "second chance"—then the students might understandably be reluctant to argue with others in academia. Adults who are returning to higher education or are at the postgraduate level may find no incongruity.

Belenky et al. (1997) reported that the aim for participating in education is different between women and men. They write that women want to be at the center and not be far out from others, and they value the comfort that being in the group brings to their learning and self-development. They write that men, on the other hand, want to excel and be out ahead of the group, and they may feel threatened by another person being too close or approaching. Asynchronous media may provide women the time needed to move the group forward as a whole, without one moving alone, too far from the center. However, this might require unusually good communication skills and literacies.

On Pacing

There was no pacing imposed during this empirical validation of the model. Four courses were each of one 6-month academic semester, consisting of about 15 lessons, each 90 minutes, plus out-of-class interactions equivalent to at least a further 200 hours and, in many cases, much more. In another two courses, the duration was double that and continued for 1 year. No pacing was used, because through previous experience, it was found that pacing induced students to adopt a performance orientation (for discussion, see Abrami & Bures, 1996, p. 38), rather than adopt a deep approach to their learning. This was an ethical decision, which negatively confounded the findings. However, literature studies later indicated that in paced (Gunawardena et al., 1997, 2001) and unpaced (McKinnon, 1976; Piaget, 1977; Renner, 1976a, 1976b) learning, students similarly reached to various levels, not completing the four stages, and mostly reaching to somewhere between the middle of Stage 2 and the middle of Stage 3, as in the present study.

In the two courses of one-year duration, findings showed that the students generally had reached the end of Stage 4. One course was a small seminar class of six second-year undergraduate students, and the other was of eight postgraduate adult students. Both were closely guided by the tutor. A similar class of adult students was unpaced and closely guided but over only six months, and they reached only to the middle of Stage 3.

All the courses were compulsory, so no student was allowed to drop out without having to repeat the course. This fact influenced the decision to have no pacing and to focus on the students' deep learning achievements.

Other Studies Measuring Transactional Distance

The present study, through close monitoring, followed each student through the learning-cycle process from an initial maximum transactional distance to less and less transactional distance. Hypertext navigation paths and serial written reports were used, together with interviews. These were very effective as measures of the progress of each student and were fairly effective as a measure of the transactional distance. The transactional distance varied during the course, becoming more reduced. Thus, the present study was a longitudinal study of measuring transactional distance.

A cross-sectional study measuring transactional distance was recently reported by Chen and Willits (1999).

Chen and Willits (1999) designed, piloted, and applied a questionnaire to measure the transactional distance in a videoconferencing course. They applied factor analysis to determine the loadings on dialogue, structure, and autonomy. They surveyed 202 students participating in 12 different courses (suggesting that their questionnaire had up to 70 items, if the 202 were treated as one cohort together for factor analysis). The items in each factor indicated that each concept of D, S, and A was complex and not simple. Their study was limited by the fact that they could not use factor analysis to discover structure, dialogue, and autonomy as three factors initially and used simply three separate questionnaires pasted together as one, and three separate analyses – one for each of them. This was likely because dialogue, structure, and autonomy are interrelated by a simplex structure, not a hierarchical structure. Factor analysis is inappropriate for simplex structures (Bynner & Romney, 1986). Dialogue and structure are related horizontally in that the amount of structure influences the amount of dialogue, so a simplex structure exists, and factor analysis should not be used. Structural path analysis would reveal this, but Chen and Willits did not report doing any path analysis. Nevertheless, they found that lower transactional distance was correlated with a higher level of learning outcome.

Their results support the use of the DML model to reduce systematically the transactional distance during a course to increase the quality and level of learning.

IMPLICATIONS AND FUTURE STUDIES

Implications and Problems Arising

The problems arising can be clearly seen: while the DML model serves as a comprehensive model for using multimedia and advanced learning technologies to achieve critical learning and develop lifelong learners, few students actually proceed beyond Stage 2 or 3—both the collaborative stages. The results falling from this are that so-called educationalists have their students afloat without winds in the doldrums. Students are using computers to chat and find (old foundational) knowledge, relating personal whims in Stage 1, and sharing interesting anecdotes in Stage 2, and not engaging academic knowledge-creation in Stage 3. While such depressing results were not seen in the present study, the obtained results were mixed. Some students could succeed to complete a full learning cycle of the model, and a couple went on to lifelong learning. But most undergraduate students found navigating the collaborative process of Stage 3 too difficult, despite the availability of scaffolding giving much additional structure to facilitate the required dialogue (from D- S+ Stage 2, to D+ S+ Stage 3).

It was also apparent that students found it difficult to move from Stage 3 to Stage 4. They reported that they could discover knowledge, views, and perspectives from other students and the World Wide Web and could make their own opinions from weighing these critically. However,

they reported difficulty in relating the theoretical perspective of Stage 3 to their own practical context in Stage 4 experientially. (A solution is given here next, rather than in the following section, for clarity.) Dialogue is very important in Stage 3, and a lot is needed. So, guided conversation is used. After largely achieving coconstruction of new understanding and knowledge, they need to move into Stage 4. To help them manage this, the tutor should increase dialogue even more by introducing synchronous conferencing. In the present study, personal presentations were made publicly to other students concerning the impact of the new knowledge on their lives and how they would try out new ideas in their lives. According to Moore (1993) the institution here should "take measures to reduce transactional distance by increasing the dialogue through use of teleconferencing" (p. 27). Students will lose some autonomy (A-) in going to synchronous mode, because they must become more empathic with others, but they will gain in dialogue (D+) and also in responsiveness to their own wants and needs and own context (with S- decrease in institutional structure).

Concerning the use of the World Wide Web and multimedia to promote students' learning, Herrington and Oliver (1999) reported that the higher-order thinking (of Stage 3 and Stage 4 here) was supported by using a situated-learning framework for relating the discussion to the student's own context. When using multimedia in situated learning, there was much less lower-order discussion and less social chat (Herrington & Oliver, 1999), indicating that multimedia could be applied to move students from Stage 1 to Stages 2 and 3. The implication here is that increasing the use of multimedia might have helped younger students cope better with the collaborative Stage 3.

Suggested Solutions

The various interactions between the student and tutor, student and other students, and student to content, and the quality, quantity, and frequencies of these constitute the academic dialogue in the educative process. The amount of dialogue needs to be carefully measured to suit each student's learning preferences and the task at hand. It is not true that simply increasing the amount of dialogue will solve all these interaction problems.

Adults generally need their prior experience and knowledge to be valued. Stage 3 entails collaborative argument. This needs an openness and receptiveness to have one's ideas be contradicted. Taking in new conflicting perspectives or information means, first, deconstruction of the existing cognitive knowledge network, where such deconstruction can be painful, especially when the prior understanding (like an old and trusted friend) has served the adult well to date. Concerning the uptake of learning technologies in their own courses, teachers, for example, have expressed a willingness to accept the innovation only insofar as it can be taken in small safe steps, permitting the teacher the safety-net option of recoursing to their proven methodology. The tutor should closely guide adults to moderate the amount of new conflicting information to prevent loss in their self-esteem. This is especially important during the Stage 3 collaborative argument and is not unimportant in the cooperative stages. Adults with a preference to field dependence (defined by Walter, 1998, as "those who gradually build towards generalisations about patterns from repeated exposure") will want to receive much information and likely enjoy cooperative learning in a group, while adults with a preference to field independence (defined by Walter, 1998, as "those who tend to see patterns and general principles in a flash of insight") are likely to want very much less input and may prefer the reflective process of collaborative learning in a group. The tutor is going to have a difficult time trying to moderate the amount of information proffered in student-to-student interactions.

To manage the quantity of new information, and the quality and frequency, the tutor could

direct cooperative massive exchanges away from Stage 2 and Stage 3 to a virtual "coffee-shop" set up expressly for this purpose, to keep the collaborative forum uncluttered. Then, the tutor will need to direct field-dependent learners to this virtual coffee-shop to assist their learning in their preferred way. This will also keep the online main forum clearer for the field-independent learners, during cooperative learning when field-dependent learners may be up-loading voluminous perspectives.

In Stage 3, there is a benefit to everyone to have diversity as wide as possible in different perspectives through which to test multiple hypotheses. Overloading to field-independent learners ought to be avoided, so careful use of hypertext is suggested here. For example, hypertext could be used in Stage 3 to give available links to reasons, keeping the main forum relatively uncluttered. It is necessary for the tutor to preascertain the field-dependence/independence of the participants and then closely guide each type separately, or to utilize some technique such as adaptive hypertext to accommodate these differences, equitably. The DML model indicates when, how, and why such adaptive hypertext will be useful. Using adaptive hypertext, the institution can provide extra interactivity to field-dependent students in the asynchronous collaborative stages, when there may be online silence among the field-independent learners. In the absence of adaptive hypermedia, the tutor should carefully tailor the amount of tutor-to-student messages to each type of learner.

Future Studies

Future studies are required to explore further why students find Stage 3 difficult to navigate through. In law and in health care and medicine, the collaborative critical-thinking skills in Stage 3 are especially important. Several institutions base their curricula now on trying to impart these skills using problem-based learning, though not all students prefer or choose this way of learning (for example, see Mangan, 1997, for law, and see Barrows, 1998, for medicine). Using this DML model, the current attention to problem-based learning processes can therefore be understood, and problem-based learning can be seen clearly in relation to the other ways of learning.

Since the present preliminary results were confounded by gender differences as well as by the use of English as a foreign language, further extended studies are underway. To investigate the correlation, if any, between the use of English as a foreign language and any potential overload (suggested by reduced reading and writing speeds by non-native-English users by Kawachi, 2002a, 2002b), identical courseware in various languages has been identified (namely Pocock & Richards, 1999), and students studying in their native language will be followed and comparatively measured.

Student motivations to learning online remain an area for further studies. How to initiate each and all the various intrinsic motivations to learn has been reported by Kawachi (2002c). However, further studies are warranted, because current taxonomies of adult motivations to learn pre-date multimedia learning technologies.

CONCLUSION

The DML model has been tested out in Japan, in large and small classes. Larger classes were divided into small groups of five or six students each. However, only in the small classes did students move successfully through the whole learning cycle. It was concluded that learning critical thinking using multimedia was better suited to graduate-level students or to small groups of tutor-guided undergraduate students. It was also concluded that tutor (the author) guidance was an important element and was too thinly spread while trying to manage five or six small groups simultaneously. In the larger classes, students did not achieve mastery of the collaborative learning,

despite trying to use the frameworks provided.

The deployment of learning technologies does not result simply in the status quo plus technology, but instead results in a new complex educational environment. The DML model tested out here provides a clear guide to technology users. However, the relative amount of time to be spent in each stage of this model is not prescribed and must be varied according to the students' own pace and according to the topic under study. Quality in learning outcomes can be defined as learning that has been achieved efficiently in terms of resources, is long lasting, and has personal meaning in the relevant desired context. To assure quality, the available learning technologies need to be utilized strategically. Different students naturally bring various learning preferences with them, and a single mode of teaching will be inappropriate. The advantage of multimedia is that multimedia can be designed to appeal to these various preferences simultaneously. The model of learning critical-thinking skills investigated here provides a scaffold to all the agents involved in education, including the administrators, teachers, nonacademic support, and students. This model as a scaffold serves as a cue and support to all these agents. Some students (or some teachers) might be uncomfortable in a particular stage of this model, where learning proceeds through a nonpreferred way. For example, field-dependent learners may prefer the synchronous cooperative stages, while field-independent learners may prefer the asynchronous collaborative stages. Nevertheless, critical thinking is a universally avowed desirable goal in adult education, and adults need to acquire these skills and should be strategically flexible in their approaches to study. The model dictates when switching to another approach is required, to proceed optimally and learn efficiently the full repertoire of skills that interlink for critical thinking. There is no argument that some courses may utilize only one way of teaching and learning. This model shows how such courseware might be improved for all-round human resource development.

Computer-mediated communications are being utilized for an increasing number of students in both conventional classrooms and at a distance, in synchronous mode and in asynchronous mode. This could suggest that more research and design resources might be forthcoming. Yet there is little research to date on why and when to utilize these technologies. In some studies, synchronous videoconferencing technologies have been bought and can technically connect the various agents for the learning process, but the tutors and institutions aim for collaborative learning, for which the synchronous technology is inappropriate and unsuccessful. Remarkable efforts are being made by many institutions worldwide to apply these new technologies for learning, yet the instructional design and the technology selected continue to be important factors causing the failures to achieve higher-order thinking skills (Abrami & Bures, 1996, p. 37). The present DML model is the only practical model proposed to date for selecting and ordering the utilization of learning technologies for acquiring critical-thinking skills. As such, the DML model constitutes an intelligent syllabus to be tested out further.

Chapter 5.12
Web-Based Multimedia Children's Art Cultivation

Hao-Tung Lin

INTRODUCTION

With the rapid advance in Web and multimedia technologies, authoring various types of multimedia content and distributing them on the Web has been very popular for many years. These technologies are applied in e-learning extensively, such as from language learning (e.g., ESL) to professional domain knowledge (e.g., computer science). In contrast, e-learning systems focusing on art domains, especially for kids or teenagers, are few. This is a notable shortcoming, because from a technical viewpoint, current advances in multimedia technology via the Web promise this kind of application. On the other hand, compared with technologies needed for more general-purpose knowledge, cultivating children's art through e-learning technology needs much more edutainment ingredients – it must be interesting and interactive and offer multimedia. Realizing this kind of e-learning is really a challenge, not only from a pedagogical viewpoint (the first ingredient) but also technical ones (the latter two ingredients).

In this article, we describe how our framework design for online authoring and presentation works. The goal of this framework is to provide a universal platform that enables students to learn more actively through sharing their own pieces easily with other learners. Peers and teachers can comment on students' work for further discussion or instruction.

To this end, a multimedia authoring and presentation tool named "My E-card" (http://media.csie.ncnu.edu.tw/haotung/myecard/) has been designed to allow students to combine different-media objects (such as a painting object, typing object and music object) into a time-ordered, synchronized multimedia document (i.e., animated sound painting). Students can import any existing media objects (e.g., image files or MIDI files) in cyberspace through a Universal Resource

Locator (URL), or create new ones from different supporting tools, such as static painting, writing an essay or composing music. We use the XML format to describe the multimedia objects and their temporal, spatial relationship metadata because of XML's high extensibility and flexibility (W3C, 2004; Villard, Roisin, & Layada, 2000). Students can resume their work at other places. They don't have to worry about data integrity or the presentation consistency of the unfinished work deposited in the server. At any stage, current piecework can be played out with synchronization to preview the result.

Research has indicated that both competence and confidence are keys to the success of active learning (Koutra, Kastis, Neofotistos, Starlab, & Panayi, 2000; Jeremy, Roy, Christopher, Douglas, & Barbara, 2000). Experimental results show that our present work enforces the highly interactive creation process, which involves acts of media creating and further authoring – an approach that leads to personal competence. Moreover, playing composite multimedia work with a synchronized manner and sharing the great work with friends reinforce personal confidence.

SYSTEM FRAMEWORK

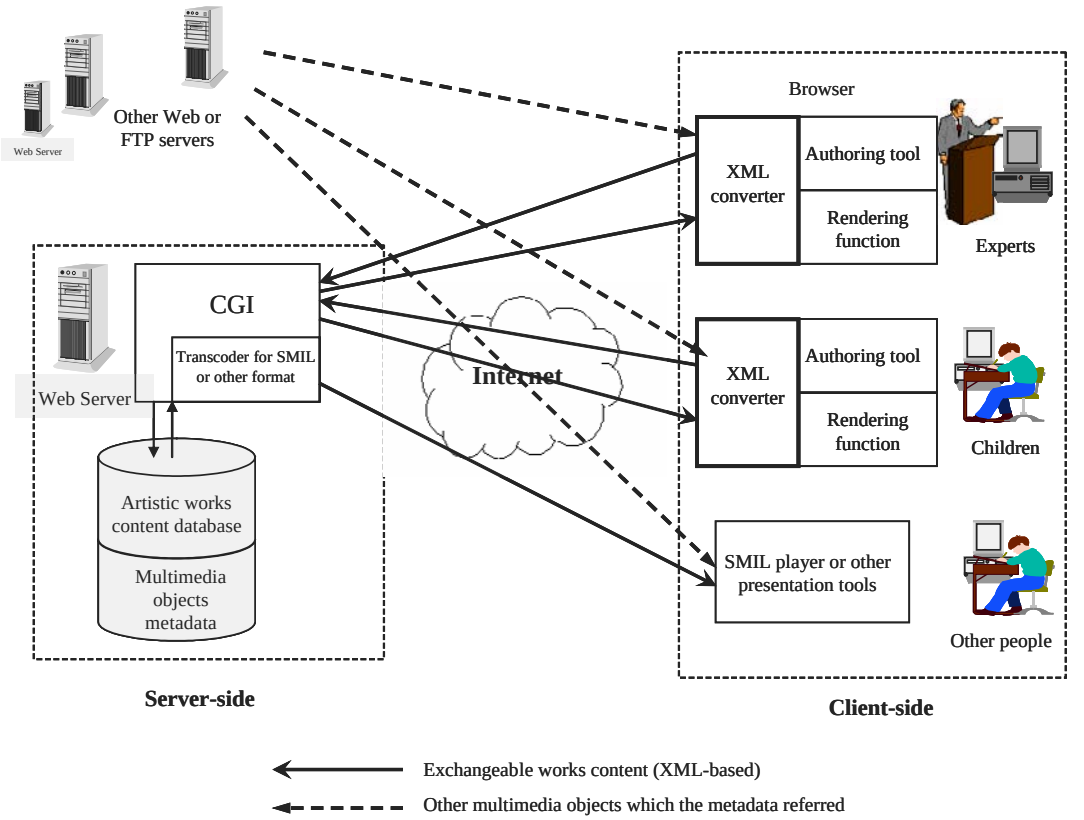
Figure 1 illustrates the proposed framework over existing web architecture, which is basically a client-server architecture: clients for authoring and presentation, servers for metadata storage and format exchange. The customized multimedia authoring and presentation program will be downloaded from the server into the client's browser and automatically executed. The program should provide users (e.g., students, teachers, experts and others) with most friendly multimedia-authoring functions and presentation experiences. All the authoring results will be transmitted to the server for storage and sharing. The server-side application gateway should maintain the meta-information of the composed, submitted artwork and handle the content exchange necessary for a different presentation tool (e.g., SMIL player). The XML-based metadata describing how different sources of media objects are composed mainly consists of three types of information: the URL of media objects (where to locate them), temporal information (when to display them) and spatial information (where to place them). The rendering function of the presentation program needs those metadata to make a best performance to users. With the help of Web technology, the framework can easily reuse a variety of existing multimedia object resources (such as images, video and audio URLs) which need not be stored in the server.

ENABLE CHILDREN TO BE INTERESTED IN THE SYSTEM

The environment and tools supported by the system may help children to cultivate their art capacity. However, how to attract children to use them actively is an important topic: It decides whether the system is worthy. We apply the following guidelines that can attract children to join this site actively.

1. Children's works should be able to be shared and viewed easily.Because it is an environment where everyone can learn through viewing other people's work, the Web site exhibits all the works created by children. Children can send their work as an e-card to relatives and friends. Through this Web-based system, people can see their works anywhere, anytime. (Bandura, 1986)
2. Children can get feedback about their work from others.Art appreciation is sometimes subjective. Many people may have different answers to the question "Is this piece a good work?" Everyone wishes to get feedback from other people, especially positive com-

Figure 1. The Web-based multimedia authoring and presentation framework



ments. For this reason, some experts in the arts are invited as online reviewers who, from time to time, examine online works and comment on them through Web interface or e-mail. (Skinner, 1968; Bandura, 1986).

3. An online contest with voting encourages children to perform.We encourage registered students to take part in an e-card contest on the basis of some specific topics. In addition to reviewers, Web visitors can vote for the work they think the best. Children must hope that their work can be a popular one. This drives contestants to keep improving their own piece. (Sulzer-Azaroff, & Mayer, 1986; Bandura, 1986)

IMPLEMENTATION

We use the Apache (Apache, 2004) as our HTTP server, incorporated with the PHP language as the server-slide Common Gateway Interface (CGI). A large number of Web users can view Flash-based Web content in their browsers (OpenSWF.org, 2004). The Macromedia (Macromedia Flash, 2004) Flash technology has been a de facto platform because of its highly interactive capability and multimedia (such as gif, jpg, wav and mp3) format support. To provide as friendly as possible an interface for end users, the Flash technology incorporated with the JavaScript Dynamic HTML control (DHTML, 2004; Dynamic Drive, 2004)

are used to develop the authoring and presentation program.

Figure 2 shows some examples of the operation in My E-card, the major authoring tool in this system. Figure 3 illustrates how the rendering function presents the children's work. There are two major media in this presentation – visual appearance and audio (music). The music can be played in several modes: background music, repeated until the end of presentation; introduction music, played just in the beginning; or throughout the entire presentation. In the third mode, the animated painting actions should be finished by the end of the music, so the rendering function normalizes all the timestamps of the significant painting actions and fits them into the time scale of the music. The painting objects appear one by one according to the time stamps, as shown in Figure 4.

The presentations of the art works are very vivid and interesting. They reflect the painting process step by step and with sound effects. The scenario of the presentation looks like a painter who is painting on the spot, accompanying the music playback. We got a lot of positive feedback from online visitors since the Web site was announced in 2003. Those people created their art works through the proposed tools and operated them well. The quality of the works they made is quite good, and sometimes beyond our expectations. Some adults even told us that they think the tools we proposed are very funny and are willing to visit the site more frequently.

Using the XML-based format to represent the metadata makes the integration of different types of media in different presentation platforms much easier. The cost of storing a large number of multimedia objects can be decreased, and the multimedia objects created by different authors can also be reused easily.

Figure 2. Some examples of the operation in My E-card. (a) The main interface of My E-card. (b) The ready-objects chooser. Children can choose the ready objects to compose a scene. (c) The function of music chooser and synchronization configuration. (d) The animated presentation process in the presentation interface. A slide bar on the top of the view indicates the presentation time. A virtual moving pen over the currently rendered object is for reality.

Figure 3. Logical view of the development rendering function

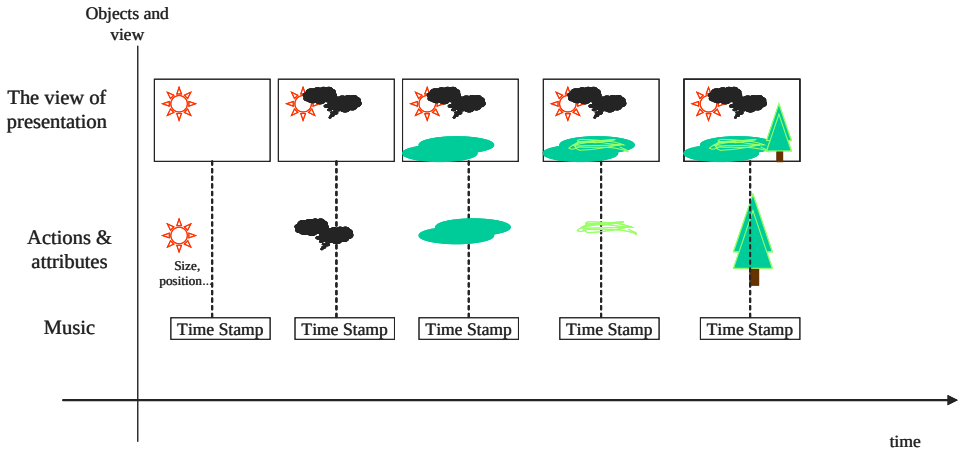

Figure 4. The diagram of the presentation modes

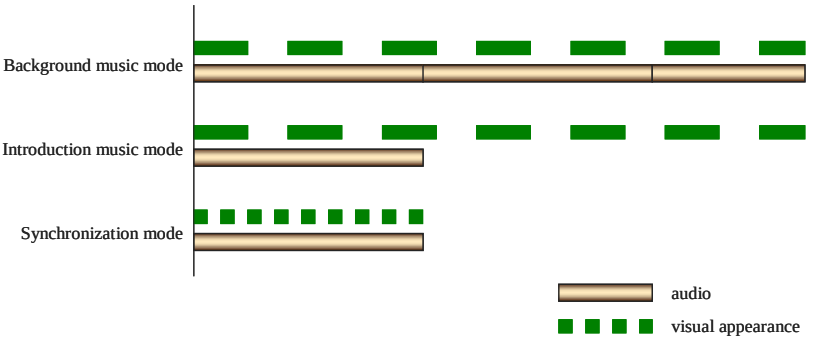

FUTURE TRENDS

In our current system, we have supported some authoring tools and the player. The works children made are stored in XML format. The XML format is easy to distribute, share and reuse, so our authoring tools and players can integrate and present the different types of the works easily. The definition of the XML tag we used has been designed for our tools. If the data can be converted into SMIL format or other standards, the works would be distributed and shared with others more easily (Boll, Klas, & Wandel, 1999; Martin, & Mulhem, 2000).

On the basis of the proposed framework, we can develop more interesting authoring and production tools for different types of art learning and cultivation, such as music composing. The tool generates MIDI data, saved in an XML-based format. Our authoring tool, My E-card, can import the finished product (e.g., MIDI file). Then, children can touch more types of art.

CONCLUSION

In this article, we described a Web-based learning environment for cultivating children's art capacity. A prototype has been implemented on a Web site especially designed for young student art learning, which has been conducted by the Military of Education, Taiwan, since 2003. The proposed Web-based multimedia authoring and presentation framework can facilitate online

artwork creation, sharing and reuse in e-learning applications. Through the easy-to-use interface of the customized tools, students can create their own pieces and share with friends. To make the presentation more interesting, a synchronization module in rendering function replays a vivid, animated multimedia presentation in a form as close as possible to the original.

To advance the worth of the framework and the system, we are inviting artists and professionals in different art or education domains to assist us in designing an objective evaluation mechanism. The results of evaluation will offer us more aspects of system promotion.

KEY TERMS

E-Learning: Education via the Internet, network, or standalone computer. Network-enabled transfer of skills and knowledge. e-Learning refers to using electronic applications and process to learn. e-Learning applications and processes include Web-based learning, computer-based learning, virtual classrooms, and digital collaboration. Content is delivered via the Internet, intranet/extranet, audio or video tape, satellite TV, and CD-ROM.

SMIL: Synchronized Media Integration Language, a markup language designed to present multiple media files together. For instance, instead of using a video with an integrated soundtrack, a separate video and sound file can be used and synchronized via SMIL. This allows users to choose difference combinations, e.g., to get a different language soundtrack, and permits text transcripts to be optionally presented; both options have accessibility benefits.

Synchronized Multimedia Document: Multimedia systems usually integrate different types of data streams, including continuous media (e.g., audio and video) and discrete media (e.g., text and still images). Media data must be presented at precise time instants defined by the rate of presentation. A media data stream schedules presentation of samples within a given time base. In this way, objects in the same time base are synchronized.

Chapter 5.13
Student-Generated Multimedia

Mathew Mitchell
University of San Francisco, USA

INTRODUCTION

This entry looks at the role of student-generated multimedia (SGM) in helping students more effectively achieve meaningful outcomes. The entry first looks at the theory and research behind multimedia learning and then goes on to address the specific case of student-generated multimedia. Mayer (2001) defined multimedia as the presentation of material using both words and images, and then subsequently defined multimedia instruction as a "presentation involving words and pictures that is intended to foster learning" (p. 3). The implications of these definitions are important because they delineate two key aspects to thinking about multimedia. First, multimedia products do not need to use video, animation, or interactivity. More importantly, Mayer's definitions focus on multimedia's potential benefits as a learning tool rather than as a technological device.

While there has been a strong body of research supporting the learning benefits of multimedia under specific conditions (e.g., see Mayer, 2001), there has been little research done on the potential benefits of student-generated multimedia. Within the larger context of educational thinking, this seems odd as there is general support for the basic idea that students learn better if they are the authors or creators of significant learning products (e.g., see Reigeluth, 1999). The theme of the constructivist research base has been that students tend to construct a deeper understanding of content if challenged to solve ill-defined problems within a relevant, real-world context. More specifically, there has been a consistent body of research that indicates students learn conceptually demanding material better when they construct self-explanations (Chi, 2000). One of the hallmarks of well-designed student-generated multimedia challenges is that they seem to invoke the self-explanation effect. Despite these factors, relatively little attention has been paid to the potential benefits of SGM. In a recent book (Brown, 2000) containing 93 vignettes from America's "most wired campuses," only five of the vignettes were about student-generated products. A more recent article investigating computer-using activities of both teachers and students (Zhao & Frank, 2004) used no measure of student-generated products. They looked at high-school classrooms, but the nearest measure to SGM was labeled "student inquiry," and their

results indicated that less than 14% of students engaged in these inquiry kinds of activities such as conducting student research using the Web. Given that computer technology provides great opportunities for students to relatively easily and effectively create significant learning products, it would seem reasonable that future research into computer-learning technologies explore the arena of SGM.

WHY MULTIMEDIA?

If the learning of specific material is easily accomplished by most students, then there is no need to incorporate multimedia instruction. For example, creating a multimedia product is typically more time intensive relative to the creation of a new text product. Thus, using multimedia makes the most sense if the specific learning challenge for students is difficult for them to master using traditional methods of instruction. In such a case, multimedia products may provide the extra instructional boost that will make a difference to learners mastering difficult material. Mayer's (2001) cognitive theory of multimedia provides an explanation for *why* the appropriate use of multimedia can be especially helpful in learning complex concepts.

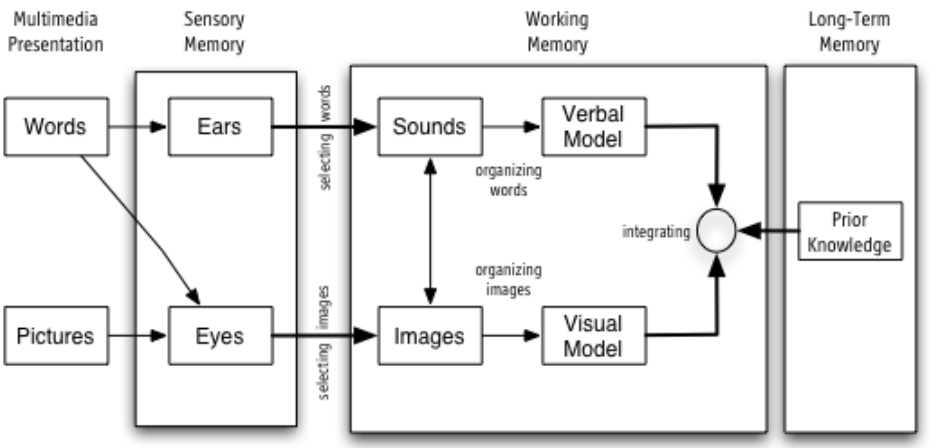
Consistent with the above line of thinking, SGM is probably best incorporated into the learning environment when the conceptual material under study is both difficult and essential for students to master. After all, to create multimedia, students need to learn about creating images and audio, they still need to know how to use text, and typically the most difficult design challenge is integrating all of these elements into one cohesive product. However, multimedia learning challenges may more effectively facilitate students' learning of complex material at a much deeper level than possible with exams or papers. For example, take the case of analysis of variance for doctoral students. This statistical concept and technique is both challenging for them to understand well and essential for their future work as academics. Under these conditions it may make sense to incorporate SGM learning challenges into the classroom. However, for simpler conceptual material such as finding the mean, it is likely an inappropriate use of time and resources to use SGM challenges. Of course, what is challenging and essential for students is dependent on grade level and a variety of other factors. Yet, given that a teacher, a department, or a school has identified particularly difficult-to-achieve outcomes, they may want to consider using SGM learning challenges. An additional benefit to using a multimedia approach to learning conceptually challenging material is that it is much more flexible compared to text-based approaches (such as essay papers) in terms of meeting the needs of learners with a wide array of learning styles. This is because multimedia allows learners to demonstrate their understanding using more than one mode of communication. As this entry will discuss in more detail below, the main potential benefits of well-designed SGM instructional challenges is that they tend to facilitate active learning in students through self-explanation and relevance.

A COGNITIVE THEORY OF MULTIMEDIA LEARNING

It is difficult to understand the value of SGM without a grounding regarding the cognitive benefits of multimedia learning in general. A leading cognitive researcher in terms of the learning benefits of multimedia is Richard Mayer (2001). While other researchers have proposed models of multimedia learning (e.g., Hede, 2002), Mayer's model (see Figure 1) seems the most complete based on a strong foundation of closely aligned research.

The focus of Mayer's (2001) model is on meaningful learning (operationally measured as transfer or problem solving in most studies).

Figure 1. Mayer's cognitive theory of multimedia learning



However, if the type of learning outcomes desired can be described as the retention of facts, then multimedia formats for learning seem no better than other formats such as text (Mayer).

Mayer's (2001) model describes what optimally happens when active learning is going on. Specifically, Mayer defines active learning as the three-pronged process of selecting, organizing, and integrating information. The basic idea is that when active learning is optimized, then meaningful outcomes can be more effectively reached. In his model, information is presented through words or pictures. Note that words can be taken in primarily through the ears or the eyes depending on whether one is using audio narration or written text. Mayer's model predicts that we select from the presented information a subset of it that will be processed in working memory. This selection of information (in the form of sounds and images) is next organized into coherent models (both verbal and visual). Finally, in the last stage of active learning, integration occurs between the verbal model, the visual model, and the learner's prior knowledge. Mayer's thinking is that when a learner has both a verbal and visual model of the information, as well as some prior knowledge that can be used to make sense of the information, then the process of integration and subsequent understanding of the material will be enhanced.

One key is how to prime active learning so that meaningful outcomes such as problem solving can be met. In essence, Mayer (2001) proposed that there are three major cognitive priming agents for active learning: cognitive load, social agency, and self-explanation. The vast majority of existing research has been on cognitive load. The idea behind cognitive load is that our visual and auditory capacities are extremely limited. Since these channels can easily become overloaded, one potential benefit of multimedia learning is that it can present complex information in a format that minimizes potential overloads. How does one do this? Mayer and Moreno (2003) proposed that there are five specific overload situations, and they put forth nine solutions to those problems (based on a review of the current research). Those nine solutions were called off-loading, segmenting, pre-training, weeding, signaling, aligning words and pictures, eliminating redundancy, synchronizing, and individualizing. Many of the nine solutions can be optimally met using multimedia solutions that integrate audio narration and visual images while reducing or eliminating the use of visual text. Mayer's simplest guiding principle for creating multimedia is to construct a concise narrated

animation, a type of multimedia presentation that uses synchronized audio narration along with visual material that is concise and uses a meaningful structure (such as a cause-and-effect chain).

Of the nine solutions, the one with the least amount of research behind it is individualizing. For example, students who have low prior knowledge but high spatial ability best learn from multimedia presentations. However, what about other types of learners? How can they best be accommodated? This is a rich area for future research (e.g., see Mayer and Massa, 2003). Cognitive load may also be age related. For instance, Mann, Newhouse, Pagram, Campbell, and Schulz (2002) provided recent evidence that some forms of cognitive overload may not be as critical for younger learners (12 years old in their study). On the other hand, Van Gerven, Paas, Van Merrienboer, Hendriks, and Schmidt (2003) provide evidence that multimedia instruction may be more effective for elderly learners (64.5 years was the mean age of their sample) due to a reduction in perceived cognitive load.

While cognitive load has received the majority of the research attention, the other two cognitive priming agents are equally fascinating and deserve further research. The priming agent called social agency refers to the idea that social cues can prime the conversation schema. The benefit of this is that the learner will expend greater cognitive effort when they feel they are part of a conversation than when they are listening to a more formal narration. Two recent studies (Mayer, Fennell, Farmer, & Campbell, 2004; Moreno & Mayer, 2000) found that simply using a script with "I" and "you" to better connect with the audience had better results in terms of student learning than using the standard third-person narrative approach. One can surmise there may be additional ways to prime the conversation schema.

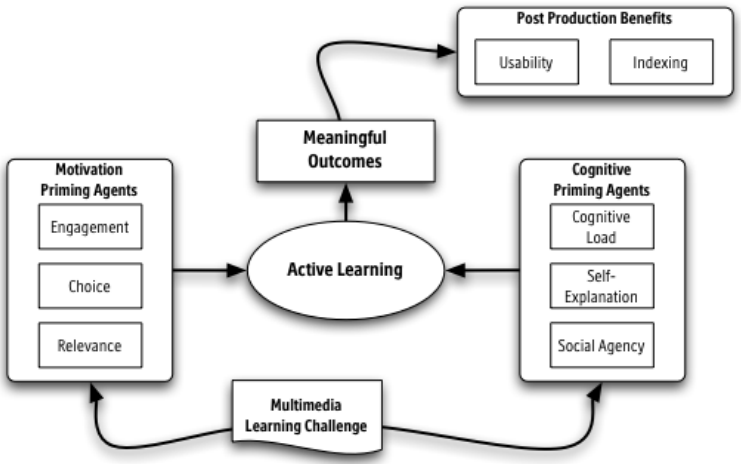
The final priming agent called self-explanation refers to the idea that if a learning experience can get the learner to be involved in self-explanation, then that will result in greater cognitive engagement. For instance, Mayer, Dow, and Mayer (2003) tested the idea that if the learner is encouraged to answer conceptual questions during the learning experience, then that will result in a higher level of learning. Indeed, they found support for their conjecture through the simple use of presenting learners with a conceptually demanding question that the learner could not fully answer before receiving the multimedia presentation. Their explanation of the results was that such a rich prequestion primes the learner to be more actively engaged in learning the material (in order to answer the prequestion) while watching the multimedia presentation.

TOWARD A THEORY OF STUDENT-GENERATED MULTIMEDIA

Mayer (2001) has presented the most compelling model of multimedia learning to date. While Mayer's model is likely incomplete, it nonetheless offers a foundation for understanding when and how student-generated multimedia may be effective. Using Mayer's model as a guide, a model for SGM is suggested by the author and presented in Figure 2.

The first focus of this proposed model is on meaningful outcomes. In the general model of multimedia learning, outcomes were operationally defined as learning measured by transfer tasks or problem solving. Similarly, SGM is probably best used when the conceptual material is both difficult for students and essential for them to master such as the analysis of variance for doctoral students in a statistics course. The reason for pragmatically limiting SGM to material that is difficult and essential has to do with the time-intensive nature of such projects. It is simply not worth an instructor's or student's time to invest in SGM unless it facilitates the accomplishment of difficult and essential outcomes.

Figure 2. Student-generated multimedia model



The proposed model of SGM posits that the most expeditious way to have students reach those meaningful outcomes is through active learning. The purpose of using an SGM learning challenge is to encourage key priming agents to be activated. This model includes Mayer's (2001) three key cognitive priming agents: cognitive load, social agency, and self-explanation. In addition the model posits that there are three motivational priming agents: engagement, choice, and relevance.

Research suggests that student-generated products in general can be motivating to students if the constraints for the products fit key criterion. One key area of supportive research comes from Benware and Deci (1984), who put forth their own hypothesis for active learning. Specifically, they defined active learning as learning in order to teach others. They hypothesized that active learning where the student is "... learning material to teach it will lead to enhanced learning and to a more positive emotional tone than learning material to be tested on it, even when the amount of exposure to the material being learned is the same" (p. 756). Benware and Deci's study, as well as some subsequent studies, provide general support for this approach. Their hypothesis could be framed as a specific instantiation of a constructivist learning environment and as supportive of the self-explanation aspect of Mayer's model. Importantly, their research suggested that not only did students learn better when provided with an active-learning prompt, but that they also felt more engaged with learning the material. Other motivation research (e.g., Mitchell, 1993; Schraw and Lehman, 2001) indicates that there are key motivational priming agents activated when a learning environment is high in situational interest (i.e., an interest generated due to the environment rather than a preexisting individual interest). Key aspects of high-situational-interest learning environments include engagement, choice, and relevance (or meaningfulness).

While many of the motivational and cognitive priming agents for active learning might be incorporated into a nonmultimedia student-generated product, multimedia pragmatically offers the simplest way to integrate all of the key cognitive and motivational priming agents for active learning. In addition, SGM uniquely provides the postproduction benefits of usability (the resulting product can be shared and viewed by current and future students) and indexing through the creation of a multimedia library.

Cognitive Agents

The SGM model suggests instructional practices based on the cognitive priming agents of cognitive load, social agency, and self-explanation. Cognitive-load research has generated the most recommendations. At a very basic level, this research suggests that SGM both off-load (i.e., reduce cognitive load by using more than one processing channel) and synchronize (i.e., reduce cognitive load by synchronizing visual and auditory material) when creating a product (Mayer & Moreno, 2003). These are extremely basic suggestions as they should be a part of any multimedia presentation. At a deeper level, cognitive-load research also suggests that students make sure to provide a meaningful structure to their products (Mayer, 2001). Two approaches that can help toward this end are conciseness (i.e., exclude extraneous material and highlight essential material) and organization (providing an appropriate structure). The most ambiguous level of suggestions for cognitive load surround the need for interactivity to meet individual difference needs. One interactivity approach that can help is self-pacing, which reduces cognitive load by allowing the learner to control the pace of the presentation (Mayer, 2001). However, it is likely there are additional techniques that would also meet individual difference needs that have yet to be identified in the research literature.

Research on social agency suggests that personalizing a presentation through using "I" and "you" in a script rather than speaking in the third person tends to prime the conversation schema, resulting in greater cognitive effort (e.g., Mayer et al., 2004). This is a technique that students can easily use to create more effective SGM learning products. The notion of social agency lends itself to the idea that using a dialogue structure (such as novice-expert or pro-con) may also prime the conversation schema in a listener.

There exists an impressive body of research (e.g., see Chi, 2000) indicating that deep levels of self-explanation have a very positive effect on learning. For example, Mayer et al.'s (2003) work suggests that if the learner engages in self-explanation, then that will result in greater cognitive engagement. This elevated level of engagement is what Mayer et al. think leads to better learning results. While there may be a number of ways to prime self-explanation, one reasonable design criterion may be to ask students making SGM to contextualize their presentation by connecting the concept to something familiar or relatable to them. This challenge to contextualize will likely activate self-explanation. From the perspective of SGM rather than researcher-generated multimedia, it appears that self-explanation is probably the most important cognitive agent explaining the effectiveness of SGM learning challenges.

Motivational Agents

There are three general recommendations the SGM model suggests: engagement, choice, and relevance. In a recent review of research, Schraw, Flowerday, and Lehman (2001) offered several suggestions on how to increase classroom situational interest, but the strongest predictor of a high-situational-interest classroom can be explained by enhanced levels of student *engagement* (Mitchell, 1993). The primary benefit of using SGM learning challenges is that they tend to encourage students to be actively engaged in their learning. A second suggestion from the research is to offer meaningful choices to students. In some SGM contexts, meaningful choice would seem to be a natural technique to incorporate ("Choose one theory we have studied in class to become an expert in. Your challenge is to teach future students about the essence and relevance of this theory using a multimedia format."). A third suggestion from the research is that relevance is of critical importance (Schraw, Flowerday, & Lehman, 2001). In most SGM learning challenges, students can be asked that their product explain to the target audience the relevance of the specific

concept they are presenting. When students need to explain a concept to others, one of the key factors to creating an effective explanation is to contextualize the information. Thus, for students engaged in SGM learning challenges, the need to contextualize their work probably activates both self-explanation and relevance as priming agents for active learning.

Postproduction

There seem to be two key positive contributions of SGM in the postproduction phase. One of these benefits is mainly for the instructor and future students: Indexing through the creation of a library of multimedia projects provides future students with a library of case studies. Just as filmmakers learn from one another's work, students can learn from the multimedia work of previous students. An easily accessible library of student work can allow future students to assimilate the techniques of past students, thus providing a foundation for developing better and more effective SGMs in the future. The second benefit is usability, wherein the resulting product can be shared and viewed by the current and future students. The ability of multimedia products to be easily shared with other students in the present and future makes an SGM learning challenge more practical and motivating. Just as putting on a theatrical play can enhance motivation because one is putting on a show for a real audience, SGM seems to offer similar benefits through its usability.

EXPLORATIONS INTO SGM

The purpose of this section is to point the reader to key studies on SGM. A relatively large amount of literature has looked at the role of hypermedia and student-generated products, but these studies have been left out because they tend to be text intensive. Instead, studies that were more closely aligned with the spirit of Mayer's (2001) cognitive theory of multimedia are included, that is, studies where the multimedia products represented a better balance and synchronization between the verbal (audio narration) and the visual.

Programming

Probably the best known research that fits under the rubric of SGM was conducted using the LOGO programming language. Papert (1980) wrote extensively about the value of students constructing their own mathematical understanding through this intuitive programming language. More recently, Kafai (1995) and Kafai, Ching, and Marshall (1997) extended the research using LOGO to look at the power of multiple mathematical representations while engaged in software design. As they put it, "While knowledge reformulation is an important feature of learning through software design, personal expression of one's ideas is another" (Kafai et al., p. 118). Their research used fourth and fifth graders who were given the challenge of creating a multimedia learning product that would teach other students about the key concept of fractions. The products students created in this environment displayed a deeper level of understanding of fractions than would normally be expected from the age group. While the research touches many issues, the bottom line is the results indicate that learning to teach via creating SGM learning products seems to result in a deeper understanding of difficult conceptual content.

Spreadsheets

Spreadsheet software has also been used as a multimedia learning tool. Two studies by Mitchell (1997, 2002) looked at the learning-to-teach approach using Microsoft Excel spreadsheet software. The products in both of these studies combined words and images to create learning environments. The words were formatted as text and the images were mainly in the form of interac-

tive raw data that resulted in the end user being able to see dynamic changes in key statistical calculations and graphs. Mitchell (1997) looked at such an approach to understanding foundational statistical concepts, while Mitchell (2002) used a similar approach for students better understanding advanced analysis of variance techniques. Both studies used doctoral students in education as the sample. The results from these two studies supported Benware and Deci's (1984) active-learning hypothesis both in regards to better learning and enhanced motivation through a greater level of engagement. Many of the learning benefits observed in these studies had to do with students developing a deeper connection between statistical techniques and specific research designs, as well as enhancing their interpretive abilities.

Movies

A more generic approach to SGM learning challenges takes the form of movies that integrate visual and audio material. This general approach can more easily be adapted to meet a wider variety of content-learning needs. The most common format for these multimedia movies is as a QuickTime movie (Apple Computer, 2002) since the QuickTime architecture both supports, and can integrate, many different image, video, and audio formats.

In an early study using multimedia, Carver, Lehrer, Connell, and Erickson (1992) identified 16 major thinking skills required of a multimedia designer. They worked with middle-school students and found great support for the development of cognitive skills. One of the conclusions of their study called for the development of "broader theories of assessment that are appropriate for complex tasks like design" (p. 402). Later, Wilson (1999) conducted a study using the middle-school environment in mathematics. Students were put into small groups that created multimedia documents demonstrating their understanding of mathematical problem situations. Wilson found great support for the self-explanation variable: "As one student stated, 'I learned that when you have to teach others you understand better yourself'" (p. 147). Wilson concluded that using multimedia involved a process that cannot be duplicated with more traditional single-media approaches such as writing a paper or creating an illustration. Specifically, Wilson thought there was an important additional level of learning that occurred when students use multiple representations within one product. A recent study by Liu and Hsiao (2002) found that making multimedia was effective in terms of engaging students cognitively and motivationally. They posited that the key to this engagement was putting students in the position of being a designer.

Two recent studies reported on SGM within technology-oriented courses. Steed (2002) looked at senior undergraduates in a course about multimedia and learning. She wanted to know whether peer and target-population evaluations influence the production of student-generated multimedia. Steed's conclusion was that feedback from an audience is a powerful influence on implementing changes to multimedia projects. Neo and Neo (2002) looked at undergraduate students in an interactive multimedia course where they were allowed to design projects of their own choice. Using a survey instrument, Neo and Neo found that students rated the multimedia design process very highly because (a) it was challenging, (b) they were able to be creative thinkers, and (c) they thought the use of multimedia was a more effective approach to presenting their concepts than other alternatives (such as written papers).

Mitchell (2003) looked at SGM learning challenges within two different courses for doctoral students in education (one course called Creativity and the other Motivation). The study looked at how well Mayer's (2001) theory predicted the quality of resulting student products, and whether Benware and Deci's (1984) active-learning hypothesis predicted student motivation. Mayer's theory effectively identified better student products due to the

use of parsimony, audio narrative, personalization, as well as other features of Mayer's model. From a motivational perspective, students appeared to show greater engagement and attention to details, and perceived themselves as co-constructing the curriculum to a level not present in former non-multimedia versions of the same courses.

Two related studies (Andreatta & Mitchell, 2004; Mitchell, Capella, & Andreatta, 2004) took a closer look at the use of SGM with a foundational-level statistics course for doctoral students in education. Students were given two randomly assigned statistical concepts they had to turn into multimedia learning products over the semester-long course. The multimedia products needed to combine audio narration with visual images. Students first completed the audio narrations, received feedback from the instructor, and then went on to complete the full multimedia products. Students found these multimedia learning assessments to be very challenging but more worthwhile than more traditional forms of assessment such as tests or written papers. Especially apparent was the importance of the self-explanation aspect of the SGM model: Since the students were struggling to understand these new statistical concepts, the challenge to clearly and convincingly teach someone else about the same concept pushed them to deepen their own understanding of the topic through the use of analogies, contextualization, worked examples, and other learning devices.

FUTURE TRENDS

SGM learning challenges seem to hold great promise for educators who want to create environments that will both motivate students and push them to learn the target content at a deeper level of understanding. As the practical bottlenecks surrounding the creation of SGM become lessened due to better software and better hardware storage capability, it is likely that more instructors within regular content-driven courses will become interested in this approach. Much of the current research has been in the content area of mathematics. Yet, since creating multimedia is not content specific, it is likely that instructors in more varied academic areas will start using this approach. The educational research community has a large role to play in our understanding of the key learning conditions that need to be in place if SGM learning challenges are to be truly beneficial for student learning. Multimedia is not a magical wand that automatically creates better learners: The support of the research community will be needed so that future instructors can make informed decisions about whether SGM is a worthwhile and practical approach for them to use with their students.

CONCLUSION

Mayer's (2001) cognitive theory of multimedia has been helpful in understanding the basic conditions under which multimedia learning can be effective. His model, which focuses on meaningful outcomes through active learning, can easily be adapted to the special case of SGM. The proposed theory of SGM in this overview suggests that there are both cognitive and motivational factors influencing whether SGM learning challenges will result in students attaining meaningful learning outcomes. An additional potential benefit is the flexibility by which making multimedia can meet the needs of students with a variety of learning styles. Many learners have difficulty learning and communicating in text-dominant environments. Making multimedia allows students to demonstrate their understanding using a much greater variety of communication tools, such as images, that may fit their particular learning style more effectively. While there is a commonly held view today that students learn best by active learning (e.g., see Reigeluth, 1999), the key instructional issue is how to effectively create the conditions that maximize

the probability that each learner will engage in active learning. SGM learning challenges offer one potentially powerful approach to creating the conditions that would prime motivational and cognitive agents, resulting in active learning and, consequently, a deeper understanding of important conceptual content.

KEY TERMS

Active Learning: The three-pronged process of selecting, organizing, and integrating information. The basic idea is that when active learning is optimized, then meaningful outcomes can be more effectively reached.

Cognitive Load: Refers to the limited capacities of the visual and auditory channels in working memory. Since these channels can easily become overloaded, one potential benefit of multimedia learning is being able to present complex information in a format that minimizes potential overloads.

Concise Narrated Animation: This type of multimedia presentation uses synchronized audio narration along with visual material that is concise and uses a meaningful structure (such as a cause-and-effect chain).

Meaningful Outcomes: Operationally measured in most research as transfer or problem solving. More generically meaningful outcomes refer to outcomes that are typically difficult yet essential for students to master.

Multimedia Instruction: A presentation using both words and pictures that is intended to promote learning.

Priming Agent: Refers to any structural feature of a learning environment that increases the likelihood that active learning will take place.

Self-Explanation: Chi et al. (1989) used the term to describe their observation that effective learners established a rational for the solution steps in a problem by pausing to explain the example to themselves. Within multimedia, the working idea is that if a learning experience can prompt the student to be involved in self-explanation, then that will result in greater cognitive engagement.

Social Agency: The idea that social cues can prime the conversation schema. The benefit is that the learner will expend greater cognitive effort when they feel they are part of a conversation than when they are listening to a more formal narration.

Student-Generated Multimedia (SGM): The specific case when students create multimedia products rather than the instructor or outside developer. The purpose of SGM is to serve as a conduit for enhancing student learning of conceptually challenging material.

Student-Generated Multimedia Learning Challenge: The purpose of using an SGM learning challenge is to encourage key priming agents to be activated. The purpose of the structure of such a challenge is to maximize the likelihood that students will achieve meaningful outcomes through the creation of student-generated multimedia products.

Chapter 5.14
An Embedded Collaborative Systems Model for Implementing ICT-Based Multimedia Cartography Teaching and Learning

Shivanand Balram
Simon Fraser University, Canada

Suzana Dragicevic
Simon Fraser University, Canada

ABSTRACT

Information and communication technologies (ICT) have created many new opportunities for teaching, learning and administration. This study elaborates a new embedded collaborative systems (ECS) model to structure and manage the implementation of ICT-based pedagogies in a blended learning environment. Constructivist learning, systems theory, and multimedia concepts are used in the model design and development. The model was applied to a third-year undergraduate multimedia cartography course. The findings show that regardless of student background, implementing effective ICT-based learning pedagogies can be managed using the ECS model.

INTRODUCTION

Integrating information and communication technologies (ICT)—specifically computers, networks, and the Internet—into higher education has created new opportunities for teaching, learning, and administration. Indeed, the role of ICT in the administration of the higher education process has been reflected in national initiatives such as the 1997 Dearing Committee of Inquiry

into Higher Education in the United Kingdom (Dearing, 1997). One of the recommendations of the Dearing Committee was the adoption of national and local ICT strategies to improve the effective and efficient use of resources by U.K. education institutions. Canadian higher education has echoed these strategies and has also increasingly used ICT in the improvement of the quality of distance-education models (Farrell, 1999). The diffusion of information and communication technology into higher education can be attributed to its potential to leverage education processes toward richer and more rewarding learning and management environments (Mitchell, 2002).

In teaching and learning, ICT is a platform on which key learning skills can be efficiently integrated into existing curriculum to boost learner motivation, deepen inquiry, accelerate learning, and widen participation among traditionally isolated groups (Hassell, 2000). Moreover, teaching core ICT skills such as computer operation and programming prepares students to function and succeed in an increasingly information-based society. However, some authors have pointed out that excessive optimism about the micro and mega benefits of ICT in education can develop into broken promises (Selwyn, 2002). These broken promises can adversely influence the adoption of ICT in educational contexts. While most educators agree that ICT has transformed the traditional education process and, hence, demands a new way of thinking, some have pointed out that achieving and verifying useful ICT educational benefits will require strong theoretical evidence, embedded analysis, and research to surmount the associated structural and cultural barriers (Kenway, 1996).

The utility of ICT in providing and retrieving information is of immense value to educators. Instructional designers are now better able to include a range of ICT-based pedagogy into curriculum design and delivery. Many accept that the technology itself does not ensure learning but acknowledge that it enhances traditional instructional systems to deal with modern-day literacy that is a key component of all education goals. Literacy is now generally considered as a multimedia construct (Abbott, 2001). Multimedia improves upon the traditional text and speech formats of interacting with knowledge by integrating other forms of media, such as audio, video, and animations into the learning experience. This has made information more accessible and understandable. But the benefits of multimedia have also come with new challenges. Using multimedia in the classroom is a clear departure from traditional expectations and requires a new mindset and commitment from educators and administrators to ensure effective implementation. Challenges also arise due to the lack of consistent baseline experience to guide the integration of multiple media into the curriculum. Moreover, the wide range of multimedia tools available present a technical challenge to educators who must select instructional technologies to match pedagogical strategies and desired learning outcomes (Abbott, 2001). These challenges demand a flexible and systematic mechanism for managing multimedia tools in traditional learning. Systems theory provides a useful foundation to develop such a management mechanism. In systems theory, the key components of the process are identified and managed separately but as a part of an integrated and functional whole. The resulting systematic structuring ensures that valid models for pedagogy inform the learning process, and that the quality of education is maintained and improved through dynamic interactions between learners and educators.

The utility of ICT in promoting sharing and collaboration among learners is also highly desired. This is reflected in the many content management systems (CMS), such as WebCT (http://www.webct.com), that empower educators to implement synchronous and asynchronous collaborative environments in distance-learning models and in online support for face-to-face instruction or blended-learning models. Socially

mediated constructivist learning theory, where learners explore and discover new knowledge, is the foundation for the collaborative learning paradigm. In face-to-face collaboration, individual and group interactions take place to varying degrees, and finding the appropriate balance is one factor that influence teaching and learning effectiveness (Norman, 2002). Mediating these interactions with technology also presents challenges. Research has shown that non-technology learners in traditional learning settings who do not have access to desired levels of technology support are less willing to use and interact with the learning technology (Watson, Blakeley, & Abbott, 1998). This challenges educators to embed the ICT-based collaborative learning pedagogies into the curriculum structure and design.

The goal of this study is to elaborate on a new embedded collaborative systems (ECS) model for structuring and managing the implementation dynamics of ICT-based pedagogies in a blended learning environment. The specific questions addressed are as follows: How can we engage students in more meaningful learning activities to develop multiple skills of relevance? How can we achieve a useful balance between teacher-centered learning and student-centered learning? The literature on constructivist learning, systems theory, and multimedia education provides the theoretical basis for developing the model. The model was applied to a third-year undergraduate multimedia cartography course of 47 students with no prior knowledge of multimedia and with basic computing skills. The results show that regardless of student background, implementing effective ICT-based learning pedagogies can be managed using the ECS model.

PROMOTING MULTIPLE SKILLS OF RELEVANCE

The focus on the mastery of cognitive and technical skills in the modern-day classroom is a tendency inherited from traditional learning systems. There is now increasing evidence in the workplace to suggest that in the complex problem-solving environment of the real world, the ability to link classroom knowledge with soft skills is a requirement for success. The capability to work in teams, being an enthusiastic and good communicator, infectious creativity, initiative, willingness to learn independently, critical thinking, analytical abilities, self-management, and ethical values are the main soft skills that are highly valued by employers. These new requirements place additional responsibilities on educators to impart knowledge or hard skills together with soft skills in teaching and learning activities so as to prepare learners to function beyond the classroom. This raises the question: How can we engage students in more meaningful learning activities to develop multiple skills of relevance? This question can be examined using a foundation of constructivist learning theory. In this theory, learning is characterized by shared goals and responsibilities, and knowledge is constructed in a discursive environment. Social networking and peer encouragement help motivation and aid individual learning experiences.

Collaborative and cooperative learning have their origins in constructivist learning theory. The goal of collaborative learning is to help learners display individuality and creativity in working with a group toward achieving targets. For collaborative tasks, rewards for achievements are allocated by comparative or normative evaluation systems. In cooperative learning, the focus is on efficiency and effectiveness in achieving a common goal in socially interactive settings (Piaget, 1926; Vygotsky, 1978). In this approach, rewards are allocated based on the quality or quantity of the group product measured against a predefined standard. Although collaborative and cooperative learning share similarities, they differ in their assumptions about competition. Collaborative learning assumes conflict as a part of learning, while cooperative learning tries to minimize

this conflict (Bruffee, 1995). One way to resolve this contradiction is to implement the learning approaches in a way so as to extract the positive learning benefits from each.

BALANCING TEACHER-CENTERED AND STUDENT-CENTERED LEARNING

Implementing multiple learning skills activities requires a balance between teacher-centered and student-centered learning within the contact time limitations of the face-to-face classroom. Thus, efficient course management and structuring become important needs with which to keep track of the evolving course dynamics. Norman (2002) outlined a model that defines the interaction space among a set of agents and objects in the learning process. In the model, two sets of agents (instructors and students) and two sets of objects (course materials and course products) overlap to form a complex interaction space. This results in six intersecting areas that form regions where a combination of two or more agents or objects exists. The usefulness of this interaction model is that it shows the variety of interacting elements that require management during the learning process. But while the model provides a comprehensive description of the interactions, it does not deal explicitly with how to balance these dynamic interactions during the learning process. This raises the question: How can we achieve a useful balance between teacher-centered learning and student-centered learning? This question can be examined using a systems theory approach.

Systems theory can be used to manage the instructional tools used to facilitate teaching and learning among the agents. In this way, the theory guides the efforts in balancing the load between student-centered and teacher-centered learning. The theory considers the teaching and learning process to be composed of a set of tightly interrelated pedagogies that can be used to communicate and deliver educational content (Bertalanffy, 1969). Based on the systems approach, together with the constructivist paradigm, a wide range of possible pedagogies can be identified. Examples of these pedagogies include learning contracts, brainstorming, debate, observation, simulation, case study, discussion, and forum. By integrating these approaches systematically, an equitable balance between teacher-centered learning that communicates knowledge and student-centered learning that integrates all levels of Blooms Taxonomy (knowledge, comprehension, application, analysis, synthesis, and evaluation) can be achieved.

MULTIMEDIA CARTOGRAPHY TEACHING AND LEARNING

The use of computer-based technologies in geography teaching and learning has a long and rich tradition (Gold et al., 1991). This stems from the influence of the quantitative revolution on many areas of the subject. Spatial information studies (encompassing geographic information systems and science, remote sensing, digital cartography, and spatial analysis) are a product of that quantitative influence. Over the last decade, ICT and specialized research software for geography, in general, and spatial information studies, in particular, has caused many changes to the community of research, learning, and teaching practices in these areas. Spatial information studies educators are now battling with how best to balance knowledge transmission with the necessary software practice in the learning process. The "cookbook" approach of traditional lectures and independent student learning of computer skills are two extremes in the learning spectrum of an increasingly computer-driven curriculum. Clearly, any solution must deal with establishing structures for an equitable distribution of the

pedagogies across the curriculum and focus the pedagogies on skills students need for success in further studies and the workplace.

Cartography encompasses the art, science, and technology of making maps and requires diverse technical and creative skills for effective practice. The use of multimedia in cartography education serves two interrelated functions: as an instructional tool and as a product development tool. Instructional frameworks to incorporate multimedia-based instruction into the curriculum must be consistent with existing theories of teaching and learning. This has been emphasized by a number of researchers (Alessi & Trollip, 2001; Benyon, Stone, & Woodroffe, 1997; Ellis, 2001; Najjar, 1996). The multiple representation (MR) framework allows the inclusion of knowledge domains within multimedia (Kinshuk & Patel, 2003). The MR approach involves the selection of multimedia objects, navigational objects, and the integration of multimedia objects in the representation of the knowledge domains. Teaching strategies and styles are also important factors in multimedia learning, as they impact learning. The benefits of multimedia education include improved learning retention, portability, modularity, enhanced visualizations, efficiency in instructional design, and learning consistency (Hede, 2002; Yildirim, Ozden, & Aksu, 2001).

The use of multimedia authoring tools in designing course products enables learners to develop and construct enhanced mapping products. This forms the basis of multimedia cartography, in which the paper map is transformed into an enhanced digital map that integrates multiple media to communicate visual and oral expressions of spatial information to the map reader (Cartwright, Peterson, & Gartner, 1999). These multimedia maps are accessed through CD-ROM, the Internet, or specially designed Web-mapping services. The benefits of multimedia maps include dynamic and multifaceted representation of space and time, superior map production and dissemination, improved information and knowledge transfer, and greater map accessibility.

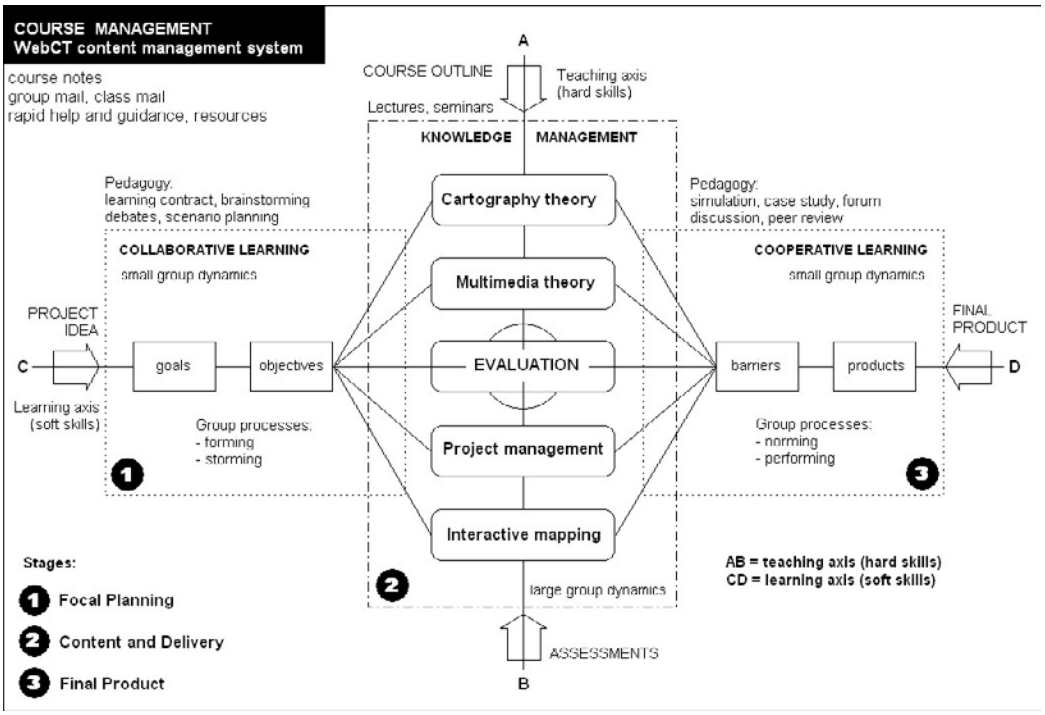
EMBEDDED COLLABORATIVE SYSTEMS MODEL

The embedded collaborative systems (ECS) model is designed based on principles from constructivist learning theory and systems theory. The goal of the model is to improve the quality of student learning in the face-to-face classroom. This is achieved with a focus on the development of multiple learning skills and on independent learning. The model's structure is shown in Figure 1.

The collaborative, knowledge management, and cooperative working spaces are three distinct overlapping interaction spaces that are defined in the model. The overlapping structure strengthens the process and provides connectivity among the stages of focal planning of projects, delivery of course content, and preparation of final course products. The knowledge management workspace occurs in the classroom, where all students receive the same content through lectures and seminars. The collaborative and cooperative workspaces occur during small group laboratory sessions or alternatively in informal meetings among students.

The teaching (AB) and learning (CD) axes serve as both workflow and information flow pathways in the model. These axes control the levels of hard and soft skills that are integrated in the learning experience. The hard skills or teaching axis deals with the substantive course content. This content is normally stipulated by institutional curriculum policies and is implemented using traditional pedagogical tools such as lectures, seminars, and panels. The knowledge management phase of the process is implemented in large groups to encourage critical thinking and discussions. Students develop individual and active learning habits during all stages of the hard

Figure 1: The embedded collaborative systems (ECS) model



skills implementation. The course outline and content together with the assessment requirements drive the nature of the interactions that occur along the teaching axis.

The soft skills or learning axis characterizes the collective and social interaction experiences of students working to achieve targets in a group environment. Examples of pedagogies that can be used involve group projects, learning contracts, brainstorming, simulation, forum, discussions, and case studies embedded in real problem-solving contexts. The intersection of the learning and teaching axes provides an opportunity for formative evaluation. Formative evaluation is an important component of the process, as with it, we are able to establish how students are integrated into the learning experience and how satisfied they are with the learning environment. Formative evaluations include interviews and survey questionnaires, and corrective action is immediately implemented to control any identified imbalances. Evaluations take the traditional form of cognitive assessments using normative testing instruments.

The use of multiple pedagogies provides students with the opportunity to experience deeper learning as they master new concepts by manipulating and refining previous knowledge. The pedagogical tools and the instructional medium appropriate for each stage of the learning process are described and explained in Table 1. The flexibility of ECS model allows students to pursue topics of general interest during the group projects. This supports the assumption that learning is a lifelong process, and learners have a role in designing what they learn.

Achieving a balance between student-centered and teacher-centered learning is inherent in the ECS model. During the initial stages of the model implementation, teacher-centered cognitive learning is at a high level, whereas student-centered learning is at a low level (Figure

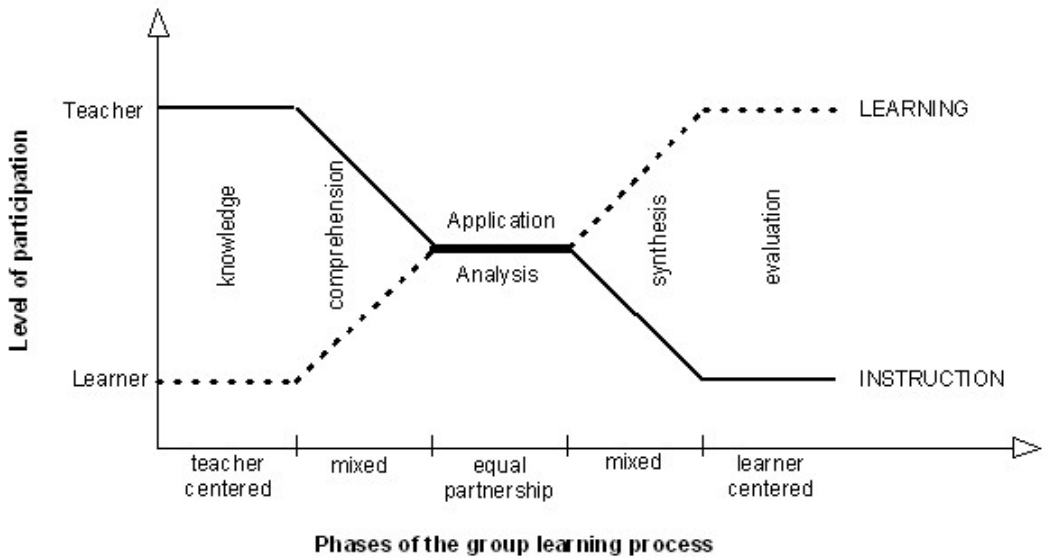
Table 1: Pedagogies and instructional media used in the ECS model

Pedagogy	Description of the Pedagogy	Instructional Media	Stage in the ECS Model	Targeted Skills
Presentation	Instructor-centered lecture notes and student-centered communication of project results	Multimedia, videotape, graphic visuals, text	1,2,3	Hard and soft skills
Discussion	Exchange of ideas and opinions among students–students and teacher–students; discussions are guided by reflective questions	Graphic visuals, text	1,2,3	Soft skills
Demonstration	Instructor-centered presentation of example of skills to be learned; use of expert to present case study	Software, the Internet, graphic visuals	2	Hard skills
Drill and Practice	Exercises such as assignments to reinforce skills	Software, text	2	Hard skills
Tutorial	Individual learning through practice and feedback	Software, text, the Internet	1,2,3	Hard and soft skills
Group work	Small group work on defining projects and allocating tasks	Software, graphic visuals, text, multimedia	1,3	Soft skills
Simulation	Experimentation with small version of reality that is to be described and understood	Software, graphic visuals, text, multimedia	1,3	Soft skills
Gaming	A user-friendly environment for testing specific rules and their effects on determined goals	Software, text	3	Soft skills
Discovery	Problem solving through trial and error	Software, graphic visuals, text, multimedia	1,3	Soft skills
Problem solving	Applying skills to find solutions to real problems	Software, videotape, graphic visuals, audio, text, multimedia	3	Hard and soft skills

2). At the beginning of the collaborative stages, a progression is seen through a fuzzy period of mixed learning toward an equal partnership in learning between teacher and learner. Thereafter, students gradually become equipped with the skills and motivation to undertake active and independent learning. Eventually, instruction is replaced with independent learning, as the full spectrum of Blooms Taxonomy is covered. The timing of the introduction of the collaborative and cooperative tasks coincides with the stages of the learning processes shown in Figure 2.

The ECS model is optimized for blended learning environments, where face-to-face instruction is supported and complemented by online instruction. Content management systems (CMS) such as WebCT (http://www.webct.com) offer comprehensive administration tools with which to deploy complex pedagogies that can emerge using the ECS model. The use of systems theory allows the educator to identify the major pedagogical components that will best achieve the desired learning outcomes. In addition, systems theory integrates the knowledge and pedagogy of the process through rigorous alternatives assessments. Each separate component of the process is analyzed for relevance and then integrated to consolidate and expand individual learning. This

Figure 2: The dynamic phases of the group learning process



framework structures the learning environment, provides a mechanism for understanding inter-relationships, and provides task balancing and process management benefits among others. The central aspect is that a systematic framework for group interactions is established that allows teams to define roles, define protocols for independent working, and devise strategies for individual accountability.

APPLICATION OF THE ECS MODEL

Cartography Course Background

The multimedia cartography course used to test the model was at the third-year undergraduate level and consisted of 47 students. The total contact duration was 13 weeks. Two hours of formal lectures and two hours of computer lab work were compulsory, guided sessions each week. The lectures were delivered to all students at the same time, while the computer labs were conducted in three sessions with not more than 20 students attending per session. The rationale for multiple lab sessions was to ensure that students had access to computer resources and were able to receive individualized attention from the teaching assistant. The classroom and lab settings exposed students to both teacher-centered instructions and learner-centered instructions. Students initially had little knowledge of multimedia concepts, cartography theory, or relevant software tools. But this situation was ideal for investigating the ECS model for learning effectiveness among students and the management of the learning process.

Designing learning structures that stimulate and promote enhanced student motivation is perhaps the most crucial aspect of learning (Edstrom, 2002). Identifying motivations allows instructors to develop strategies for redirecting student goals toward more meaningful and rewarding learning experiences. A questionnaire survey was implemented at the beginning of the cartography course to determine student motivation and rationale. The open-ended anonymous question:

"What do you expect to achieve by attending this course?" provided valuable responses (Table 2). Learning about Internet mapping and cartography principles was the most frequent statement given by students who responded. This indicated that student motivation was generally aligned with the course objectives, and hence, more time would be available for the instructor to focus on preparing engaging content. As is expected, some students were interested in software learning to improve their job prospects and others on obtaining the necessary credits toward graduation.

The open-ended anonymous question: *"What can the instructor and teaching assistant do during the lectures and labs to make you learn better?"* indicated that the most frequent expectation was for clearly explained example-based content (Table 3). The information obtained from the two questions guided the selection of pedagogical components in the ECS model, so that the learning process was balanced by student expectations and institutional curriculum policies.

Content Structuring and Knowledge Management

The first 4 weeks were dedicated to formal lectures and guided practice on the use of software tools. Moreover, cases were analyzed and best practices extracted such that students became familiar with general practices in the subject area. This forms the knowledge management phase of the model, in which learning proceeds through incremental steps, and individual learning is emphasized. The subsequent weeks were structured so that knowledge management at an individual level and collaborative project at a group level reinforced each other for an enhanced learning

Table 2: Motivation of students in the multimedia cartography course

What do you expect to achieve by attending this course?	**Frequency of Statements (%)** (Number of Statements = 47)
Better understanding of mapping on the Internet	13 (27.7)
Expand my knowledge of cartographic techniques	12 (25.5)
Greater familiarity with the software to be used	7 (14.9)
Academic credits and knowledge	5 (10.6)
Others	10 (21.3)

Table 3: Students' suggestions for a better learning environment

What can the instructor and teaching assistant do during the lectures and labs to make you learn better?	**Frequency of Statements (%)** (Number of Statements = 46)
Give clear and concise explanations	8 (17.4)
Provide many examples during teaching	7 (15.2)
Present the materials at a reasonable pace	4 (8.7)
Make the content relevant and interesting	3 (6.5)
Give well-organized lecture notes	3 (6.5)
Make notes available ahead of lectures	3 (6.5)
Others	18 (39.1)

experience. Formal lectures included concepts related to cartography, multimedia, Web mapping and project management theory (Figure 1). The focus of the lectures was on case studies, and students were exposed to analytical, application, creative, communication, social, and self-analysis skills (Easton, 1982). Moreover, students were able to discuss their views freely and to listen to the views of peers. The group work and peer support operated both as additional instructions for students and as a forum for wider discussions within the course framework.

Of significance in this stage is the concept of Web-based mapping, which involves some level of computer networking knowledge (Figure 3). In a Web-mapping multimedia application, a digital map, once created, becomes a dynamic index to multimedia content. The map is hosted on a Web server, and a map server provides a dynamic link to a database to allow end users to query and interact with the map in the browser window. Although the learning curve for this particular type of mapping technology is steep, it was surprising to find that students were extremely motivated and committed to learning the software. Informal interviews revealed that the general source of this motivation came from the structuring of the learning outcomes at each stage of the process and the out-of-class support and help provided by the teaching assistant. Students were more committed and motivated when they could control how and when they learned.

Accessing notes and supplementary materials before lectures ensures that students concentrate on synthesis and analysis rather than on note taking. The new electronic media make it easy to provide additional readings based on student needs, and the online environment provides a social space for continuous conversations and support among peers. Optimal learning occurs when students share knowledge among peers in a community of practice where ideas are evaluated and adapted. In order to manage the implementation of the model, the content management tool WebCT was used for managing mailing lists, discussions, and presentation of knowledge content (Figure 4). The real-time facilities of the management tools were useful in fostering the "community spirit" outside of the classroom setting. The final multimedia cartography atlas products developed and

Figure 3: Levels of use of relevant software

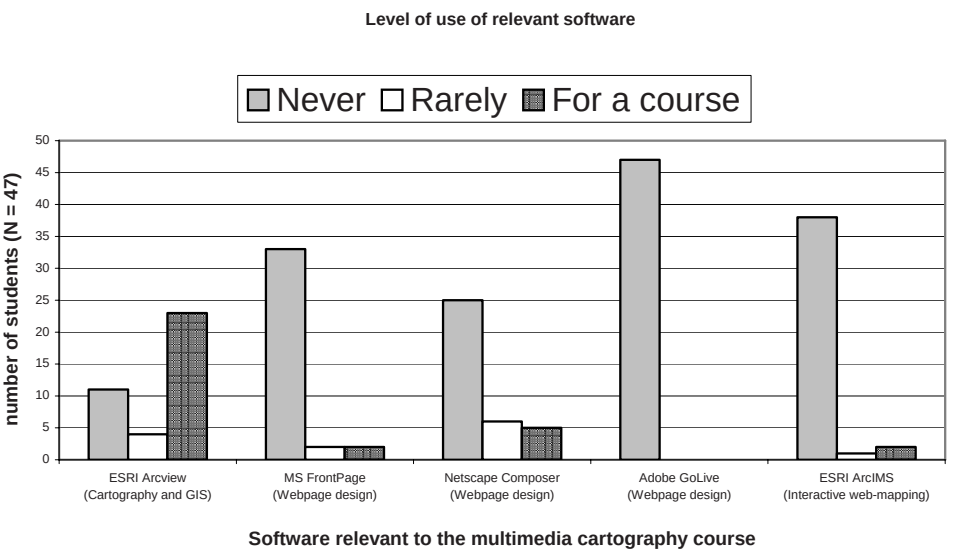


Figure 4: Model implementation using the WebCT content management system

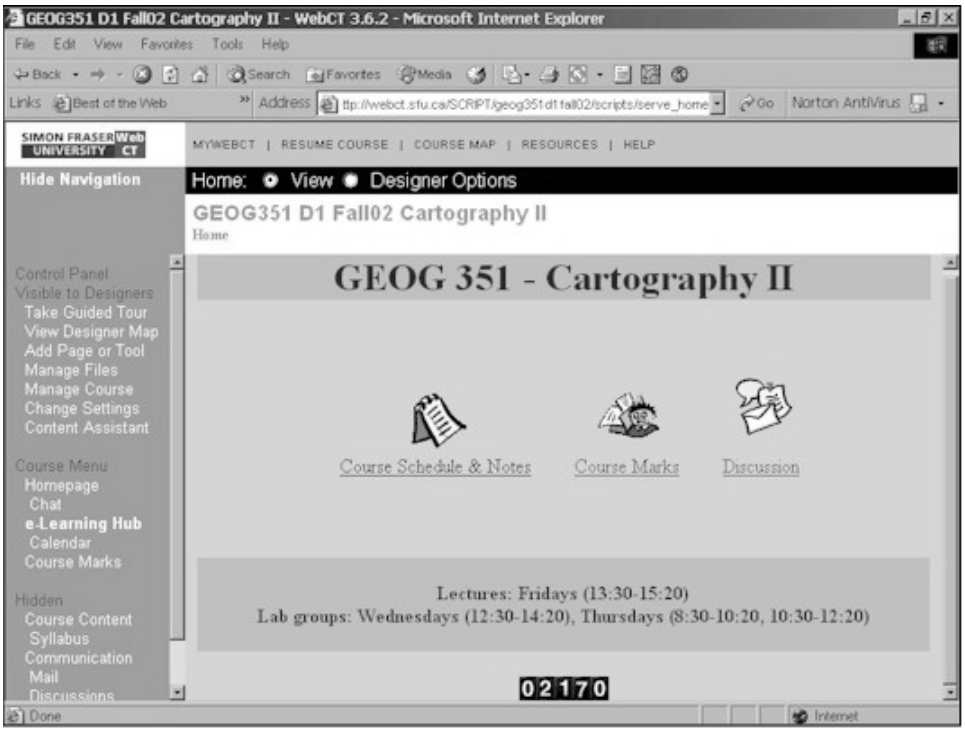

implemented by students are documented on the Web (http://www.sfu.ca/geog351fall02/).

Collaborative and Cooperative Learning

In the collaborative learning exercise, learners were divided into nine groups (average of five students per group, some randomly and some based on individual preference), and step-by-step guidelines were given to each group on the final product to be achieved (designing and creating a professional multimedia atlas), and resources (books, journal papers, Internet Web sites) available for unraveling what is to be achieved. Tasks included mastering sets of specific learning objectives and finding ways to transfer that learning to the class as a whole. There was no briefing to students on group roles. Students reported that the first set of group discussions was difficult. This was expected, but students needed to learn how to cope in a new and unfamiliar social and learning environment. The leadership role was usually assigned to the student with much to say. That leader then assigns tasks, facilitates the discussions, and ensures that meaningful results emerge from the discussions. The weekly meetings provided time for critical reflections and perusal of new materials, ideas, perspectives, and further research. Each week, the instructor met with the group to evaluate problems and progress and to offer solutions strategies. Ideas were not imposed on the groups, and this was much appreciated by the learners. Moreover, learners agreed in principle to abide by "moral and ethical" conduct during the course.

Students were involved in the initiation and definition of a relevant project. Support was provided in the form of guidance about the format of the final products to be produced, potential areas for projects, course aims and expectations, time schedules, data resources, and project

management information. In the design stage, students were encouraged to develop a concept sketch of their product and to begin the process of tool selection and task allocation. There were many opportunities for students to consult with the course instructor and teaching assistant during this stage and, indeed, for the entire course. All members of the group were encouraged to participate in the creation, assembly, and layout of content so as to ensure a uniform individual learning experience. Internet resources and books were provided to help further the process. Each group identified a member to coordinate their activities and to maintain close liaison with the instructors. The final course products were presented to peers for review, and comments were gathered by the instructor and given to each group. This feedback was useful in improving the quality of the products and establishing a standardized level. This peer review also introduced critical and reflective practices into the process (Bazeli & Robinson, 2001).

The use of information technology together with communicating and working with peers was identified by students as contributing to the success of the project. There were instances in which some students were more focused on the technological tools and less on the content. The group-learning format ensured that group members provide focus and guidance to individuals. Evidence of this peer learning was reflected in the sophistication of the cartographic products and how these products quickly diffused and were adopted by other groups. The professionalism of the final products helped in motivating students toward greater learning and explorations.

Assessment and Evaluation

Evaluations have substantial gains for individual projects and progress in the field. Moreover, the use of new ICT technology has resulted in curriculum changes and may require new ways of evaluating students. In the collaborative modes of learning, the focus is on teamwork and communication skills, and appropriate measures of these are needed. An interim way of dealing with this is to use outside evaluators and student questionnaires. Also, multiple levels of evaluation can yield richer feedback from external, internal, and peer sources. Logging usage statistics and student interviews is another way to identify features of the course that are good and what improvements can be made so that future refinements of the process can be made.

Assessment materials were returned to students quickly, showing where improvements can be made. The exercise involved students preparing work individually and bringing it to the group. The small groups then integrated the materials using e-mail and face-to-face meetings. The small group work was then shown to the groups in a large-format presentation. The assessment also allows educators to learn about their work in a critical and reflective way so that rapid improvements can be instituted for the benefit of learners (Gerber, 2002). The assessment for the cartography course was comprised of individual assignments, group mini-project presentations, individual participation, examination, and production of a final working group electronic atlas.

All students completed a questionnaire during the formal group presentations, and some students were randomly interviewed at the midway point in the course to obtain feedback toward formative evaluations. In the group presentations, each student was required to judge the presentations of the others on a 5-point verbal scale ranging from poor to excellent. Moreover, reasons for the judgments were also requested. The general trend of the responses was toward the favourable end of the judgment scale and was justified by the respondents on two main grounds—the sophistication of the tools and techniques used for creating the atlases and the non-duplication of these techniques across the groups. Students clearly indicated that these were attributed to the efficient small-group work and the collaborative

settings in which they occurred. However, one shortcoming identified was the lack of time. While this was unavoidable given the constraints of the semester and curriculum, techniques and tools for time and project management were again reinforced such that facilities for handling this shortcoming were available to them beyond the course. Another shortcoming identified was the variation in skills within the groups. Although students recognized the difficult logistical problems that this can cause, they nevertheless felt that the group's experience would probably have been more rewarding with balanced skills. One way to deal with this is to make greater use of learning styles and skills inventory to categorize students into the small project groups. However, this will demand a trade-off between efficiency in the course logistics and effectiveness in implementing the ECS model. The two comments below characterize the general attitude of students:

"The projects and presentations overall were very impressive and obviously well thought out. The presentations give an overall view of the work-effort placed within each group."

"In general I would like to say that all the atlas were very different concerning layout and information, but most of them were really very good."

A summative evaluation in the later stages of the course elicited responses on the following questions using a 4-point scale (4 being most favourable):

- The assignments and lectures were [unrelated—well related]; mean score = 2.61 (n = 36)
- The exams and assignments were on the whole [unfair—fair]; mean score = 2.81 (n = 36)
- The marking scheme was on the whole [unfair—fair]; mean score = 2.92 (n = 36)

These results from the summative evaluations are inconclusive. While they indicate a general positive weight to the statements, the aggregations of different student backgrounds and experiences makes any interpretation uncertain. The issue of a learner capability to judge curriculum content and implementation is still unresolved in the literature. Nevertheless, the informal interviews and the level of accomplishment in the final atlas products provide strong indication that the collaborative learning process, as implemented using the ECS model, was indeed effective in managing and task balancing the components toward the intended products.

FUTURE TRENDS

The further development and integration of ICT into multimedia cartography education is dependent on three factors: access to ICT tools, instructors' knowledge of effective ICT use, and more studies on the benefits of ICT and multimedia in student learning. Access and instructor knowledge are issues best handled from the wider policies and practices of higher education administration. Systematic research is needed to further establish the role of ICT in learning.

The software and hardware needs for geography education are enormous. Centralized servers for demonstrating and hosting Web-mapping services, the multiplicity and constantly changing software tools, and the need to redesign current computer laboratories to accommodate collaborative group learning are some of the central considerations that will influence the wider adoption and diffusion of an ICT in the geography curriculum. A troubling issue for multimedia cartography teaching and learning is software licensing arrangements that can sometimes be a barrier to using certain software tools in the learning process. This, in some ways, dictates the eventual skills that students can achieve. Technology providers will need to seriously

consider pricing mechanisms so that academic institutions are better able to afford and maintain basic technological infrastructures to implement core teaching and education programs. There has been some progress in this area, with mechanisms such as university campus licensing that enable widespread use of some software tools for teaching and research.

With the gradual expansion of the home as a center of learning, arrangements for students to use university resources at home promise to be a major issue, especially with respect to copyrights and off-campus licensing agreements. University libraries hold a key position in this regard. Already, electronic books, or e-books, are a common feature of many western university library catalogs, and there has been growing evidence to suggest that some of the more progressive university libraries have already begun to redefine their roles as information gateways to act as the intermediary between the user and information (Dowler, 1997). Electronic data archives, multimedia reuseable learning object databases, subject portals, and continuing skills training for students are ways libraries have begun to accept their changing roles in university teaching and learning. A common thread in all the transformations has been the impact that ICT has brought to the university and classroom with respect to administration, teaching, and learning.

Existing models of multimedia cartography teaching and learning have been mostly descriptive. These models have been useful in understanding the mechanisms in operation and in enabling comparisons to be made across different learning contexts. The results from these studies have enabled educators to generally conclude that ICT and multimedia have positive benefits for learning. However, not much is known about the critical factors and how they influence learning. Systematic investigations of predictive models in diverse contexts provide the next steps for understanding the factors of ICT and multimedia that affect learning. Following along this line will be new learning tools, with which intelligent agents will guide learners through knowledge nodes and learning activities using hypermedia and multimedia in much the same way as the intelligent help assistant acts in the Microsoft Office software products.

CONCLUSION

The ECS model presented is based on a holistic perspective of learning as complex interactions between multiple agents, physical and social spaces, and instructional technologies. Although the model can be used in hypothesis testing, the main goal is to provide instructional designers and educators with a tool for managing the main factors that need to be considered when designing ICT-based pedagogies. This model provides the framework for good instructional and course-structuring design that takes into account the diversity of learner styles and provides engaging interactions among students.

The use of ICT and multimedia pedagogy in cartographic education is still in the early stages of understanding and development. There are numerous possibilities and pitfalls. But given the early stages of diffusion of multimedia tools in education, the current focus among practitioners is on developing strategies and standardized protocols to produce effective multimedia components that blend engagement and entertainment into a single learning environment. Moreover, collaborative processes aid the pedagogical move toward student-centered learning.

The embedded collaborative systems model was developed to structure and understand the dynamics involved in the implementation of multiple learning skills activities. The implementation involved 47 students in a multimedia cartography course. The course was conducted in a blended learning environment, and discursive group learning was the foundation of the learning experience (Thorne, 2003). Each group defined

project content, prepared a proposal, defended their proposal in front of their peers in a formal conference-type presentation, received feedback from peers, and used the feedback to improve their group's project. Also, the other groups judged each group on presentations. This forms the cooperative phase, where individuality and group opinions are merged for consensual learning.

In summary, the issues in this study, namely, how to implement effective (content and experience) multimedia cartography training and education to learners of diverse backgrounds, was addressed by the development and testing of a systems model for integrating the multiple facets involved in the education and training process. Within the systems model, the collaborative and cooperative learning strategies were integrated to promote individual and group development for effective multimedia cartography education and product development. The benefits of the ECS model include the following:

- Improves connectivity among the actors by embedded and continuous interaction
- Cultivates an attitude of independent learning through peer guidance and motivation
- Integrates multimedia information, thereby catering to a range of learning styles
- Provides ownership of the learning process through group and individual project management
- Develops individual social and learning skills and accountability

Chapter 5.15
Multimedia Evaluations Based on Cognitive Science Findings

Eshaa M. Alkhalifa
University of Bahrain, Bahrain

INTRODUCTION

Multi-media systems waltzed into the lives of students and educators without allowing for the time required for the development of suitable evaluation techniques. Although everyone in the field is aware that judging this type of teaching software can only come through evaluations, the work done in this regard is scarce and ill organized. Unfortunately, in many of the cases the evaluation forms were just filled in by instructors who pretended they were students when they went through the tutorial systems (Reiser et al., 1994).

BACKGROUND

In the early days, some researchers regarded the evaluation of the program's functional abilities and efficiency to be important, so they defined them as formative evaluation, and they also defined the effectiveness of the system as summative evaluation (Bloom et al., 1971; Scriven, 1967).

Others believe the evaluation of the system is unimportant, so they focused on the latter by comparing student performance in pre- and post-test questionnaires prior to and following the use of the system, learning style questionnaires that targeted their learning preferences and a subjective questionnaire that investigated whether students like the system (Kinshuk et al., 2000). Unfortunately, many of the pre- and post-tests resulted in no significant1 differences in student grades when multi-media is compared to classroom lectures or to carefully organized, well-illustrated textbooks (Pane et al., 1996). These disappointing results caused researchers to question whether or not the correct evaluation questions are being asked; for example should the test be of interactivity versus lack of interactivity, or should one compare animation with textual media (McKenna, 1995)? If Pane et al. (1996) were aware of the work done by Freyd (1987), who studied the cognitive effects of exposing subjects to a series of still images to find that they are equivalent in the reactions they elicit to being exposed to a moving picture,

then perhaps they would not have asked whether animation is equivalent to a textbook with carefully set images of all stages.

Since the problem that arose is the evaluation question, researchers continued to alter it in order to recognize what should be emphasized. Tam et al. (1997) proposed a three-part evaluation procedure that includes peer review, student evaluation as well as pre- and post-testing (Tam et. al., 1997). They were not able to get rid of the pre- and post-test evaluation, as it is the primary test for how much learning was achieved, and they still got no significant differences.

At this stage, researchers recognized that evaluations did not target the appropriate level of detail, so Song et al. (2000, 2001) presented empirical support that animation helps reduce the cognitive load on the learner. They also showed that multi-media is more effective in teaching processes than in teaching conceptual definitions, while textual presentations are better at the latter. However, all this was done in very limited test domains that lacked the realistic world of an educational system. Albalooshi and Alkhalifa (2002) implemented some of these ideas in addition to offering both textual representations and animations within the same screen to students. This supports individual learning preferences while offering multi-media systems as a cognitive tool. Such a tool requires an evaluation framework that is well informed of the justification behind its design and the way its main modules interact.

A 3-DIMENTIONAL FRAMEWORK FOR EVALUATION

In the reported cases, most of the evaluated systems failed to reflect their true abilities because some aspects of the design or effects were neglected. Consequently, a complete framework of evaluation is required to take into account all issues concerning the software and the learning process. Evaluation questions can be channeled into three main dimensions of evaluation that could then be subdivided into the various methods that form possible criteria that guide the evaluation process.

The framework will be explained through a case study that was performed of a data structure tutorial system (DAST) that was developed and evaluated at the University of Bahrain (AlBalooshi & Alkhalifa, 2003). The process started with a pre-evaluation stage, where students were all given a test and then were divided into groups of equivalent mean grades. This was done to allow each group to have members of all learning levels.

Then the pre- and post-tests were written to ensure that one set of questions mapped onto the next by altering their order while ensuring they include declarative questions that require verbalization of how students understand concepts as well as procedural questions that test if students understand how the concepts can be applied. Last but not least, a questionnaire was prepared to allow students to highlight what they regard as any weak areas or strong areas based upon their interaction with the system. The evaluation procedure for students is shown in Figure 1. Educators were also asked to fill in an evaluation form as experts.

ANALYSIS OF RESULTS

First of all, student grades were analyzed using the Analysis of Variance (ANOVA) test. This test allows the evaluation of the difference between the means by placing all the data into one number, which is F, and returning as a result one *p* for the null hypothesis. It will also compare the variability that is observed between conditions to the variability observed within each condition.

The statistic F is obtained as a ratio of two estimates of students' variances. If the ratio is sufficiently larger than 1, then the observed differences among the obtained means are described as being statistically significant. The term "null

Table 1. A three-dimensional framework of evaluation

1st Dimension: System Architecture

This dimension is concerned with the system's main modules, their programming complexity as well as their interactions. Evaluation within this dimension should be performed in any or all of the following methods:

- Full description of system modules and complete check of interaction.
- Expert survey of the system filled by experts or educators.
- Student evaluations to consider their perspective of the system.
- Architectural design must be based on cognitive science findings rather than chance.
- Everything else concerning the system design such as cost analysis and portability.

2nd Dimension: Educational Impact

This dimension is concerned with assessing the benefits that could be gained by students when they use the system. Classically, these are done in pre- and post-tests, and this is carried on in this framework with more attention given to detail.

- Students grouped according to their mean grade in a quiz.
- Post-tests are used to compare one group with system only and another classroom only. A third group attends the classroom lecture with the class group and does a pre-test, and then uses the system before doing a post-test for comparison with the other two.
- Questions in the pre/post-tests must be mapped to each other to test the same types of knowledge, mainly consisting of declarative and procedural knowledge.
- The tests should best be attempted with students who were never exposed to this material previously to assess their learning rate.

3rd Dimension: Affective Measures

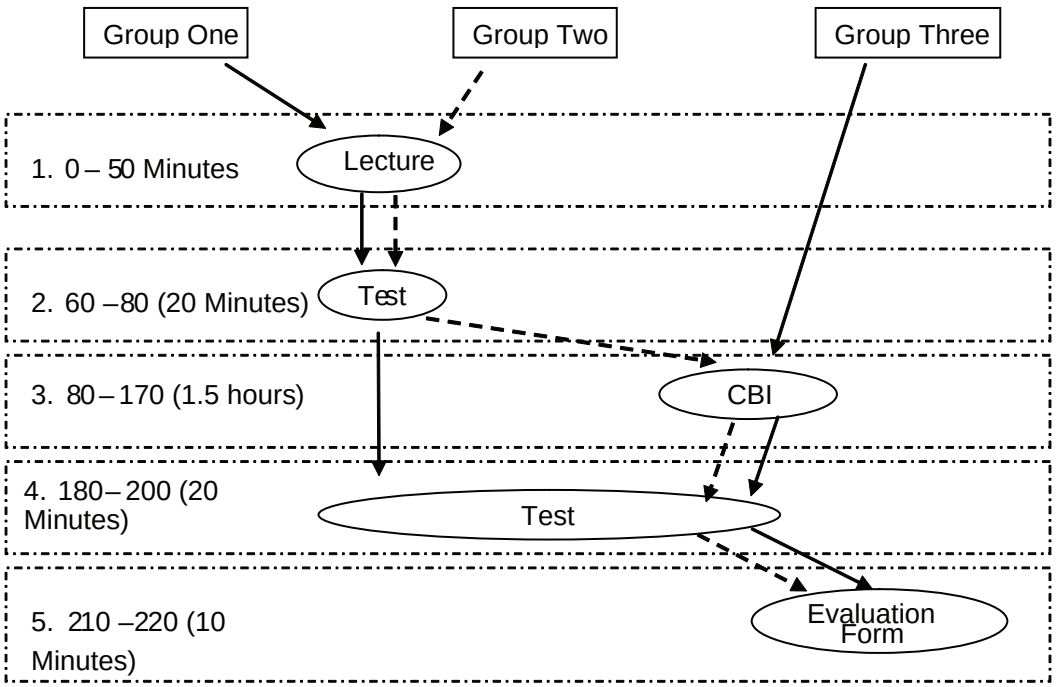
This dimension is mainly concerned with student opinions on the user friendliness of the system and allows them to express any shortcomings in the system. This could best be done through a survey where students are allowed to add any comments they wish freely and without restraints.

hypothesis" represents an investigation done between samples of the groups with the assumption that additional learning will not occur as a result of the treatment. In order to conduct a significance test, it is necessary to know the sampling distribution of F given that the significance level needed to investigate the null hypothesis. It must also be mentioned that the range of variation of averages is given by the standard deviation of the estimated means.

The ANOVA test did indeed show that there is a significant improvement in Group Two between the first test, which was taken after the lecture, and the second test, which was taken after using the system. However, this was not sufficient to be able to pinpoint the strengths of the system. Therefore, a more detailed analysis was done of student performance in the individual questions of test one and test two. Since the questions were mapped onto each other by design, it was easy to identify significant changes in student grades in a particular question type for students of group two who responded to similar questions before and after the use of the system. For example, a highly significant improvement with F=58 and $p<.000$ was observed in the question: "*Using an example, explain the stack concept and its possible use?*", which is an indication that the use of the system did strongly impact the student understanding of the concept of a "stack" in a functional manner.

Another point of view is to examine the scores by using the total average, which is 10.639, which can be approximated to 10.5, which can be

Figure 1. The evaluation procedure



used as a borderline. The rest of the scores can then be divided around this line. It was noticed that the average score of the third group was not high, yet 10 of the scores were above the borderline, while comparatively 6 scores were above it from the second group and only 6 of group one, which took the class only option. This shows the results of the third group, who took the CBI package alone and the second group, which had both the classroom lecture and the CBI package exposure to be close. It also underlines how much the second group improved their test results after taking the CBI and at the same time shows that the first group had not improved much only with the lecture learning. Alkhalifa (2001) tested in abstract logical context the effects of describing a state of a "*moving system*" versus describing it as a static system to find that this affects logical conclusions subjects eventually arrive at. This tutorial implemented those findings through this particular statistic, which revealed the effects of having animation in this multi-media system.

These results indicate that the use of the system may introduce a "limiting" effect that follows the initial introduction to the concepts (Albalooshi & Alkhalifa, 2002). Classroom lectures introduce students to the concepts, allowing them all the freedom to select all types of applications, which is in some ways overwhelming. The use of the system, on the other hand, produces a safe haven to test their ideas and strongly pursue the examples they can imagine, which helps them arrive at a solid procedural understanding of the concepts. It goes without saying that such a conclusion would have been impossible to make if the questions were not purposely set in the shown mapped fashion.

Additionally, students of groups two and three, who were exposed to the system, were asked to fill in an evaluation form composed of a series of questions as proposed by Caffarella (1987). They generally gave ratings of around 4 to 5 on a scale that went 0 to 6 with the highest for "The use of graphics, sound, and color contributes

to the student's achievement of the objectives," and "The user can control the sequence of topics within the CBI program." The lowest score was 3.559 for "The level of difficulty is appropriate for you". Therefore, it seems that the students in general enjoyed learning through the system, although they found the level of difficulty of the concepts presented challenging.

In addition to all this, three peer experts filled in evaluation forms to rate the system from an instructor's point of view and they gave the system an average rating of 5.33 on the same scale of 0 to 6.

FINE-GRAINED EVALUATION

The evaluation framework proposed here evaluates multi-media educational software at a finer level of detail than what was previously followed. The system architecture, for example, is evaluated in terms of the cognitive assumptions on which it relies. In many cases this dimension was overlooked, as in the studies that found animation and carefully organized images to be equivalent (Byrne et al., 1999; Lawrence et al., 1994) because they were not informed of the work done to show that a sequence of images are translated as animation (Freyd, 1987). In fact, there is a difference between the two in that animation presents subjects with a cognitive tool that reduces the cognitive load they endure while learning and allows them to concentrate on the transfer of information rather than assimilating the presented material into animation (Albalooshi & Alkhalifa, 2002).

The educational impact question must also be carried out at a finer level of detail than just to report total grades for comparison. Specific questions may be designed to probe key types of learning, as was shown in the presented case study.

FUTURE TRENDS

Only through a fine-grained analysis can the true features of the system be revealed. It is this type of information that allows designers to take advantage of the opportunities offered by an educational medium that offers to transform the learning experience into a joy for both students and educators alike. Consequently, cognitive science concepts represent themselves to future research as a viable means to comprehend the learning process. This would guide the evaluative process to focus on the points of strengths and weaknesses of each system rather than assess it as a whole unit.

CONCLUSION

A three-dimensional framework is presented as a means to evaluating multimedia educational software in order to resolve the shortcomings of the current evaluation techniques. It differs from the other, in that it seeks a more fine-grained analysis while being informed through cognitive science findings. The extra detailed review reveals specific strengths of the system that may have been otherwise concealed if the comparison was done in the traditional manner. In other words, this process focuses on students' cognitive interpretations of what they are presented with rather than assuming to know how they will approach the educational content presented to them.

KEY TERMS

Cognition: The psychological result of perception, learning and reasoning.

Cognitive Load: The degree of cognitive processes required to accomplish a specific task.

Cognitive Science: The field of science concerned with cognition and includes parts of cognitive psychology, linguistics, computer science, cognitive neuroscience and philosophy of mind.

Cognitive Tool: A tool that reduces the cognitive load required by a specific task.

Declarative versus Procedural Knowledge: The verbalized form of knowledge versus the implemented form of knowledge.

Learning Style: This is the manner in which an individual acquires information.

Multimedia System: Any computer delivered electronic system that presents information through different media that may include text, sound, video computer graphics and animation.

ENDNOTE

[1] This term is defined in the Analysis of Results section.

Chapter 5.16
Cognitive Functionality of Multimedia in Problem Solving

Robert Zheng
University of Utah, USA

ABSTRACT

Teaching problem solving can be a challenge to teachers. However, the challenge is oftentimes not due to a lack of skills on the part of learners but due to an inappropriate design of media through which the problem is presented. The findings of this study demonstrate that appropriately designed multimedia can improve learners' problem solving skills because of the cognitive functions media has in facilitating mental representation and information retrieval and maintenance, as well as reducing cognitive load during the problem solving process. Suggestions were made on how to apply interactive multimedia to teaching and learning.

INTRODUCTION

Problem solving skills as effective instructional strategies have been widely used in teaching and learning to enhance students' abilities to analyze, synthesize, and evaluate information during their learning processes (Hanley, 1987; Zheng & Zhou, 2006b). In the last five decades, researchers, teachers, and other educational practitioners have placed a heavy emphasis on this ability. For example, the movement of "discovery learning" (e.g., Bruner, 1961) was spawned, at least in part, by the perceived importance of fostering problem-solving skills. This emphasis on problem solving was not associated, however, with the knowledge of cognitive resources involved in problem solving. That is, it focused on the procedures of problem solving rather than investigating the relationship between the procedures of problem solving and cognitive resources that affect such procedures (Hanley, 1987; Sweller & Low, 1992). In the last 20 years, this state of affairs has begun to change with our knowledge of relevant mechanisms (e.g., working memory, cognitive load, etc.) increasing markedly. The introduction of multimedia, for instance, has reshaped our way of looking at how the information is processed in problem solving. Studies show that multimedia can improve learners' solving-problem skills, as appropriately designed multimedia tends to reduce learners'

cognitive load and increase cognitive resources during problem solving (Zheng & Smarkola, 2003; Zheng, Miller, Snelbecker, & Cohen, 2006a).

Although there are numerous studies on multimedia and cognition, little research has been done in the area of interactive multimedia and learner cognition, particularly in a situation where complex problems (e.g., multiple rule-based problems) are involved. Studies have shown that the interactive multimedia can be effective in simulating problem situations, thus providing a cognitive framework necessary for complex problem solving (Zheng et al., 2006a). Nonetheless, it is not clear whether such effectiveness is due to a difference in the design of multimedia or the cognitive functioning associated with such design. This chapter focuses on how interactive multimedia can facilitate learner problem solving by investigating:

1. The difference between interactive and non-interactive multimedia in complex problem solving
2. The difference between various forms of interactive multimedia and their impact on learners' information retrieval during complex problem solving

BACKGROUND

The Role of Media in Learning

More than 20 years ago, Clark (1983) challenged the educational community to reexamine its research design and results, claiming that most media research was confounded, and there were no significant differences among various media. Clark argued that the research should focus on method, aptitude, and task variables of instruction rather than media themselves. Kozma (1994) countered that research should be grounded in a theory that defines media in ways that are compatible and complementary with the cognitive and social processes by which knowledge is constructed. He urged researchers and practitioners to understand the dynamic relationships between media and learning, the reciprocal interaction between the learner's cognitive processes, and the unique characteristics of media. Reiser (1994) concurred with Kozma's view on media and pointed out that certain media attributes facilitate certain types of learning outcomes for particular types of learners.

Salomon (1979) in an earlier study observed that "something *within* the mediated stimulus … makes the presented information more comprehensible or better memorized by learners of particular characteristics" (p. 6). Based on the dual coding theory, Mayer and his associates (1997) investigated learners' information process in both multimedia and non-multimedia learning environments and concluded that appropriately designed multimedia can improve learning. According to the dual coding theory, learners learn better when information is presented through multiple sensory channels, rather than one channel only (Paivio, 1986). Studies (see Mayer, 1997; Mayer & Anderson, 1991; Mayer & Moreno, 2003) show that different presentation modes (i.e., words vs. pictures) and sensory modalities (i.e., audio vs. visual) may affect students' learning differently.

Working Memory and Cognitive Load

Research has found that input information such as auditory, visual, and kinesthetic information is processed through temporary storage before it is coded into the long-term memory (Baddeley & Logie, 1992; Logie, 1995). This temporary storage, also called working memory, comprises three major components: the phonological loop, visuo-spatial sketchpad, and central executive. The

phonological loop stores phonological information and prevents its decay by silently articulating its contents, thereby refreshing the information in a rehearsal loop. The central executive mechanism is believed to be related to cognitive activities such as reasoning and problem-solving. Finally, the visuo-spatial sketchpad (VSS) is believed to process and manipulate visuo-spatial images (Logie, 1995; Pearson & Logie, 2000). For example, the ability to mentally manipulate 3D images by rotating them in the mind is largely determined by the VSS function. The above components are closely related and interact among themselves in the process of problem solving (Bollaert, 2000; Mayer et al., 2003). Studies show that the working memory is very limited in both duration and capacity. Van Merrienboer and Sweller (2005) observed that the working memory stores about seven elements but normally operates on only two or three elements. When the working memory becomes overloaded with information, learning can be adversely affected (Marcus, Cooper, & Sweller, 1996; Sweller & Chandler, 1994).

Sweller et al. (1994) believe three types of cognitive load exist. They are *intrinsic load*, *extraneous* or *ineffective load*, and *germane* or *effective load*. The *intrinsic cognitive load* refers to the cognitive load that is induced by the structure and complexity of the instructional material. Usually, teachers or instructional designers can do little to influence the intrinsic cognitive load. The *extraneous cognitive load* refers to the cognitive load caused by the format and manner in which information is presented. For example, teachers may unwittingly increase learners' extraneous cognitive load by presenting materials that "require students to mentally integrate mutually referring, disparate sources of information" (Sweller et al., 1991, p.353). Finally, the *germane cognitive load* refers to cognitive load that is induced by learners' efforts to process and comprehend the material. Zheng et al. (2006a) asserted that learners' problem solving ability is correlated with the level of cognitive load. When learners become cognitively overloaded, that is, the working memory is filled with too much information, which leaves little room for thinking, their ability to solve problems can be impaired.

Recency Effect on Problem Solving

The ability to solve problems is not only affected by the amount of information held in the working memory, but also the status in which such critical information is maintained during problem solving process. While the process of problem solving draws on resources from both long-term and short-term memories, it is believed to rely heavily on the working memory for the working information in problem-solving (Baddeley et al., 1992; Logie, 1995). Capitani, Della Sala, Logie, and Spinner (as cited in Logie, 1995) conducted a study on learner information retrieval and found a high recall by subjects immediately after items have been presented. However if there was a filled delay before the recall was required, only the first few items on the list could be recalled. Logie (1995) described the former phenomenon as the recency effect and the latter as the primary effect. He believed that "the recency reflected the operation of a short-term or primary memory system" (p. 5), which was critical to the problem solving process.

It is essential to distinguish between cognitive load and recency effect because both involve cognitive resources in the working memory. The notion of cognitive load refers to the load or amount of information imposed on the learner's working memory while performing a particular task, whereas the recency effect refers to the most recent information that can be recalled in the working memory. The cognitive load study is focused on the working memory architecture and its limitations relating to the design of instruc-

tion (Paas, Tuovinen, Tabbers, & Gerven, 2003; Tabbers, Martens, & van Merrienboer, 2004; Van Merrienboer et al., 2005). The recency effect is, however, focused on the state of recalling and maintaining much needed information during the problem solving process. Zheng et al. (2006b) pointed out that one of the challenges to researchers and educators in applying multimedia to problem solving is to determine the optimal design where multimedia facilitates the recall and maintenance of critical information while keeping the working memory from becoming overloaded in the process of problem solving.

Problem Types and Cognitive Load

Problem types are related to thinking procedures in problem-solving processes (Delisle, 1997). For example, causal relationship problems require a linear thinking procedure that has a strong linear direction emphasizing the cause and effect whereas multiple rule-based problems involve simultaneously weighing several conditions/rules in mind in order to make a decision (Frye, Zelazo, & Palfai, 1995; Price & Yates, 1995). Zheng et al. (2006a) found that different types of problems may require different levels of working information in the problem solving process. For instance, multiple rule-based problem solving may require more working information than does causal relationship problem solving or single rule-based problem solving. Single rule-based problem solving, according to Frye et al. (1995), requires a straightforward deductive thinking such as applying the rule of card sorting to the action of sorting a deck of cards, whereas multiple rule-based problem solving involves a more complex, nonlinear thinking where the learner reaches a solution by engaging in a series of cognitive thinking activities such as analyzing, synthesizing, evaluating, and so forth while holding several conditions and rules in mind within a short time framework provided by the working memory (Johnson, Boyd, & Magnani, 1994; Price et al., 1995). Obviously, multiple rule-based problem solving is likely to increase intrinsic cognitive load more than the other two types of problem solving.

Spatial Ability and Multimedia Learning

Although use of multimedia for instruction can be beneficial, various learner characteristics have been found to mediate its effectiveness. One such characteristic is spatial ability. Pearson et al. (2000) noted that spatial manipulation is related to cognitive activities such as mental representation and synthesis. Logie (1995) studied the relationship among visuo-spatial ability, working memory, and problem solving and concluded that visuo-spatial working memory (VSWM) is involved in spatial-visual related problem solving and comprehension (also Pearson et al., 2000). Spatial strategies, either constructed mentally by the learner or presented as external instruction, are helpful in solving one- or two-dimensional problems including logical reasoning tasks and linear syllogisms, as well as inductive reasoning problems (Dupeyrat, 2000). Piburn and his colleagues (2005) investigated the role of visualization in computer based science education and found that learners' spatial ability is correlated with their achievement in learning supported by multimedia.

In short, learners' problem solving is affected by such factors as the amount of cognitive load in the working memory, the ability to retrieve critical information as well as maintain such information during problem solving, the types of problems that affect the information process in terms of cognitive load, and learner characteristics such as spatial ability. Characterized by multifold approaches of delivering information through multiple sensory channels, multimedia is believed to facilitate learners' problem solving.

However, existing literature is mainly focused on non-interactive multimedia studies. Little empirical research has been done to understand the cognitive functionality of interactive multimedia in problem solving.

THE STUDY

The study consisted of two sub-studies purported to find out whether there was (a) a difference between interactive and non-interactive multimedia in complex problem solving and (b) a difference between various forms of interactive multimedia and their impact on learners' information retrieval during complex problem solving. A description for each study follows.

Study 1

This study investigated whether there was a difference between interactive and non-interactive multimedia in complex problem solving and whether presentation modes were correlated with learners' spatial ability in problem solving. One hundred and fourteen students (80 undergraduate and 34 graduate students) were recruited from a large urban university in the northeastern region of the United States. Of 114 participants, 66 were females and 48 males. Participants varied in age from 19 to 58 years old, with a majority (74%) between the ages of 19 and 26.

The Instrumentation

Two instruments were used to measure (a) students' spatial ability and (b) problem solving skills. They include kit of factor-referenced cognitive tests: cube comparison and card rotation (Ekstrom, French, Harman, & Dermen, 1976) and interactive and non-interactive problem solving tasks.

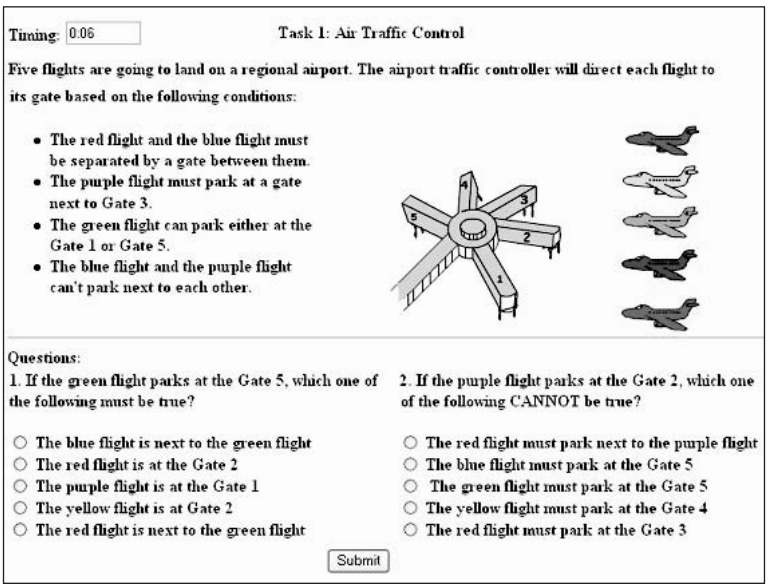
- **Kit of factor-referenced cognitive tests: Cube comparison and card rotation.** The cube comparison subtest has two parts. Parts one and two contain 21 items each, and subjects have three minutes to finish each part. Each item is a pair of cubes with different letters on the visual portions of the cube. Subjects must determine if the cubes are identical, presumably by mentally rotating one or both of the cubes. An individual's score on the cube comparison scale is calculated by subtracting the number of incorrect responses from the number of correct responses. Similar to the cube comparison subtest, the card rotation subtest has two parts. There are 10 items in each part and the subject has three minutes to finish each part. For each item, subjects are presented a target shape and eight different distractors similar to the target shape but at different rotated angles. For each of the eight distractors, subjects must determine if the distractor is the same as the target shape. An individual's total score on the card rotation scale is calculated by subtracting the number of incorrect responses from the number of correct responses on both parts.
- **Interactive and Non-interactive Problem Solving Tasks.** The problem solving tasks were developed by the author using Flash MX, Adobe Photoshop, and Microsoft Active Server Page (ASP). The five tasks were air traffic control, Tower of Hanoi, sailing boat, taking pictures, and office inspection. Each task consisted of two parts: (a) a problem presented with text format along with a visual presentation (either interactive or non-interactive), and (b) multiple choice questions. The tasks were multiple rule-based problems

that included a description of a problem situation and several mutually restricting conditions. The subject had to consider these conditions simultaneously before a solution could be reached. For example, Task 1, *air traffic control*, had a set of conditions that restricted the order and parking positions of airplanes. The subject had to consider all the conditions and then decide which flight would park at which gate without violating the conditions. Two multimedia versions of tasks were created: Interactive and non-interactive. In the interactive multimedia version, subjects were able to manipulate and move important components of the image (e.g., airplanes). In the non-interactive problem-solving version, subjects were given a static visual representation of each problem. For each problem, subjects were asked to answer two questions that measured the subject's problem solving skills. After completing the two questions, the subject clicked the submit button. A timer recorded the start and the end of the response time for each set of two questions (Figure 1).

Procedures and Conditions

Subjects were first given a spatial ability test and then categorized as low ability or high ability based on the test results. In the absence of normative data for this instrument, a median split was determined to be the most appropriate method for dividing the sample into low and high spatial ability. After the spatial ability groups were formed, subjects from the two ability levels were then randomly assigned to either the interactive or non-interactive problem solving condition. Thus, four groups were created: (a) high spatial ability/interactive, (b) high spatial ability/non-interactive, (c) low spatial ability/interactive, and (d) low spatial ability/non-interactive.

Figure 1. Sample of task 1: Air traffic control problem with questions



Results and Discussion

All data were performed with SPSS v.13. The means and standard deviations are provided in Table 1. The results of MANOVA indicated that the main effect for ability was not significant, $F(1,87) = 2.24$; $p = 1.38$. The main effect for type of multimedia presentation was significant, $F(1, 87) = 7.04$; $p < .05$. The interaction effect (ability x type of multimedia presentation) was not significant $F(1, 87) = 2.29$; $p = .134$. However, a graphic representation of the findings seems to indicate an interaction between the learner's spatial ability and interactive/non-interactive multimedia mode (Figure 2).

The findings revealed a difference between interactive and non-interactive multimedia in complex problem solving. Examination of the overall results leads to the impression that interactivity does seem to help both low and high ability learners, and that ability x presentation mode interactions may be detected with modifications of ability measures and problem solving criterion measures.

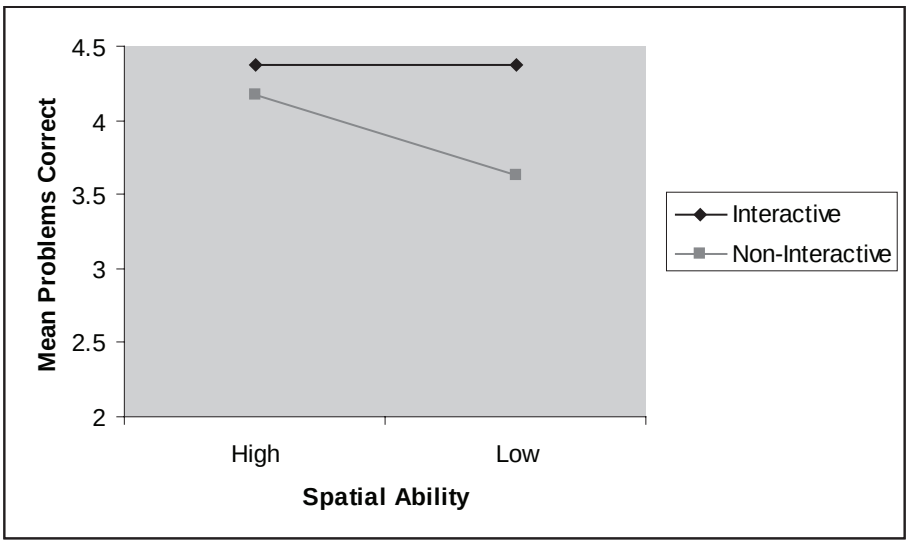
Study 2

Although the findings of study 1 indicated that interactive multimedia could facilitate learners' problem solving, it was not clear which mechanism within interactive multimedia was associated with the cognitive functioning in problem solving. Research has shown that differences in multimedia design such as simultaneous vs. successive presentation of verbal and visual information, can affect learners' information process during problem solving (Mayer, 2001; Mayer et al., 2003). It was thus hypothesized that the dif-

Table 1. Means and standard deviations for problem solving tasks

	Interactive	Non-Interactive	Margin Means
High Spatial Ability	4.38 (1.38)	3.96 (1.82)	4.17(1.60)
Low Spatial Ability	4.38 (1.66)	2.85 (2.00)	3.63 (1.97)
Margin Means	4.38 (1.50)	3.44 (1.97)	3.92 (1.79)

Figure 2. Spatial ability groups and multimedia modes



ferent design in interactive multimedia would affect learners' abilities to process information, which would in turn impact their way to solve complex problems.

Forty-five students were recruited from the same university as in study 1. Of 45 participants, 89% (n = 40) were undergraduate teacher education majors who received course credit for participating in the study and 11% (n = 5) were graduate students who volunteered to participate in this study. The average age of the participants was 21 with a range from 19 to 31.

The Instrumentation

Two instruments were used to measure students' spatial ability and problem solving skills. They include (a) the Guilford-Zimmerman Aptitude Survey Test 5: Spatial Orientation (Guilford-Zimmerman, 1956) and (b) synchronized and non-synchronized problem solving tasks.

- **Guilford-Zimmerman Aptitude Survey Test 5: Spatial orientation (Guilford-Zimmerman, 1956):** The Guilford-Zimmerman spatial orientation test requires participants to observe the position of the bow of a boat relative to the horizon and then to correctly identify the change in the boat's orientation by the change in horizon relative to the bow. The purpose of the Guilford-Zimmerman test is to assess participants' ability to mentally maneuver objects in terms of the special relationship, which is consistent with the reasoning tasks set up in this study: that is, the participant came up with a solution by maneuvering the figures and determining the spatial relationship between the figures based on the conditions and rules set in the tasks. The Guildford-Zimmerman spatial orientation test has reported a high reliability (alpha = .88) (Price & Eliot, 1975).

- **Synchronized and unsynchronized problem solving tasks:** Using the same problem set from study 1, the problem tasks in study 2 were modified to reflect a change in the task interface design. Two sets of problems were created: synchronized and unsynchronized interactive multimedia tasks. The synchronized interactive tasks included the problems and questions on the same page, whereas the unsynchronized multimedia tasks had two separate pages with one page containing the problems and the other the questions. The tasks contained five multiple rule-based problems. Each task included a description of the problem situation, several mutually restricting conditions, and two multiple-choice questions. If an error was made by the subject in any of these five problems, a point would be deducted from the total score. The total score equaled 10 points.

Procedures and Conditions

Using a blocked random sampling procedure, participants were first given the Guilford-Zimmerman Aptitude Survey Test 5: Spatial Orientation (Guilford & Zimmerman, 1956). The middle value of the distribution (median = 7.25) was determined and chosen as the cut score for defining subjects' high and low spatial ability. Subjects were then blocked into high and low spatial ability groups based on their spatial ability test score. Subjects were randomly drawn from each of the blocked groups (i.e., high and low spatial ability) to form two separate groups: the synchronized interactive multimedia group and the unsynchronized interactive multimedia group. Thus, two levels of interactive multimedia (synchronized vs. unsynchronized) were crossed with two levels of spatial ability (high vs. low) to form a 2 x 2 between subjects factorial design. In the synchronized

design, subjects were able to view the problems and questions on a single page whereas in the unsynchronized design subjects had to scroll between the pages to view the problems and questions. The independent variables included multimedia learning environments (synchronized vs. unsynchronized) and spatial ability (high vs. low). The dependent variables were test scores and efficiency scores.

Results and Discussion

The descriptive statistics for test scores are reported in Table 2. Significant differences were detected between the synchronized and the unsynchronized groups ($F_{(1, 44)} = 6.18$; $p < .05$) and between the high and the low spatial ability subjects in terms of test scores ($F_{(1, 44)} = 10.09$; $p < .01$).

The MANOVA analysis revealed that there was a main effect for multimedia groups (Wilks' Lambda = 5.64; $p < .05$) and spatial ability (Wilks' Lambda = 5.40; $p < .05$). An overall interaction between the multimedia groups and the spatial ability was detected (Wilks' Lambda = 6.48; $p < .01$) (Table 3).

Thus, with the first dependent variable, the results showed an impact of learners' performance in problem solving by the type of media employed. This was supported by the mean difference in test scores between the synchronized group (Mean $_{sync} = 5.43$) and the unsynchronized group (Mean $_{unsync} = 4.41$) (Table 2). The between-subjects tests showed a statistical significance between two groups ($F_{(1, 44)} = 6.19$; $p < .05$).

The second dependent variable of interest is efficiency, which is the number of problems solved correctly divided by the total time that it took the subject to complete the tasks. Results showed that both higher and lower spatial ability learners with the synchronized interactive multimedia obtained higher efficiency scores than their counterparts in the unsynchronized group (Table 4). There was an overall significant difference between synchronized and unsynchronized groups in efficiency scores ($F_{(1, 44)} = 11.99$, $p < .05$). Since the efficiency score indicates learners' ability to solve problems in terms of the ratio between total test scores and total response time (in seconds), it would be reasonable to assume that learners who solved more problems with less response time had more cognitive resources during

Table 2. Descriptive statistics for test scores

	Multimedia Group	Spatial Ability	Mean	Standard Deviation	N
Test Scores	Syncronized	High	6.17	1.26	12
		Low	4.64	1.50	11
		Total	5.43	1.56	23
	Unsynchronized	High	4.90	.56	10
		Low	4.00	1.47	12
		Total	4.41	1.22	22
	Total	High	5.59	1.18	22
		Low	4.30	1.49	23
		Total	4.93	1.48	45

	Hotelling's Trace	.324	6.480	.004	.245

the problem solving process. It would also imply that such learners were more effective in recalling and maintaining critical working information—a recency effect—and able to solve problems more efficiently in a short time framework provided by the working memory (Logie, 1995).

The study supported the hypothesis that the learner's ability to process information is affected by the design of *interactive* multimedia. Results indicated that synchronized interactive multimedia facilitated learners' abilities to solve problems due to a prompt recall and retrieval of working information and that unsynchronized interactive multimedia decreased learners' abilities to solve problems due to a filled delay phenomenon caused by scrolling back and forth between pages.

UNDERSTANDING COGNITIVE FUNCTIONS OF INTERACTIVE MULTIMEDIA

The previous findings support the notion that learners' abilities to solve complex problems can be influenced by the media with which the problems are presented. The findings also suggest that interactive multimedia facilitates cognitive functions in problem solving such as mental representation and information retrieval and maintenance.

Mental Representation

The dual coding theory posits that different forms of information, such as visual and auditory information, are registered through different sensory channels (Paivio, 1986). For example, the auditory information is registered through the auditory channel and the visual information is registered through the visual channel. The auditory and visual information then interact with each other within the working memory to form a mental representation of the external world (Mayer, 2001). Paivio (1986) believed that mental representation reflects the basic operation of comprehension and reasoning. When information is processed through multiple sensory channels, that is, through the channels of auditory, visual, and kinesthetic manipulation, the ability to formulate what has been perceived, namely, the mental representation of the external world, increases.

The results of our study indicated that there was a difference between interactive and non-interactive multimedia and that learners in the interactive multimedia group outperformed those in non-interactive multimedia group in problem solving (Table 1). It can be reasonably assumed that since learners with interactive multimedia were exposed to multiple sensory inputs including auditory, visual, and kinesthetic information, they were likely to form a more accurate and better mental representation of the external objects than did their counterparts with non-interactive multimedia. Researchers found that active engagement in learning such as manipulating the objects facilitates mental representation (Ploetzner, Bodemer, & Feuerlein, 2001). Clements (1999, cited from Reed, 2006) found that good manipulatives "provide control and flexibility, and assist the learner in making connections to cognitive and mathematical structures" (p. 95). Similarly, interactive multimedia enables learners to manipulate objects to simulate various situations for the possible solution, and therefore provides the kind of cognitive structures needed in problem solving.

Information Retrieval and Maintenance

Since the working memory is limited in both duration and capacity, complex problems may impose an excessive cognitive load on learners, thus affect their abilities to solve problems (Zheng et al., 2006b). According to Zheng et al. (2006a), complex problems, particularly multiple rule-based problems, have the characteristics of (a) simultaneously weighing several conditions/rules in mind before reaching a solution, and (b) consuming more cognitive resources than do single rule-based problems. They noted that it was the design of interactive multimedia rather than the interactive multimedia itself that affected the learner's ability to solve problems.

The results of this study indicated that synchronized interactive multimedia was more effective in solving complex problems than did unsynchronized interactive multimedia in terms of test scores and efficiency scores (Tables 2 and 4). This effectiveness is due to the cognitive functions that the synchronized mode of interactive multimedia displays in problem solving. Firstly, synchronized interactive multimedia tends to alleviate excessive cognitive load, thus improving efficiency in problem solving (Table 4). Unlike unsynchronized interactive multimedia, synchronized interactive multimedia provides an immediate access to the critical working information, and thus reduces the cognitive load for temporarily storing working information in problem solving. Secondly, synchronized interactive multimedia enables learners to retrieve and maintain much needed working information during problem solving. Unlike unsynchronized interactive multimedia that causes a filled delay in learners' information retrieval, synchronized interactive multimedia facilitates an immediate recall of critical information—a recency effect—during the problem solving process. Learners are able to retrieve and maintain much needed information while solving complex problems.

THE USE OF INTERACTIVE MULTIMEDIA IN TEACHING AND LEARNING

Multimedia, particularly interactive multimedia, has provided a richer environment for teaching and learning. Studies have shown that learning is effective for interactive visual images (Marschark & Hunt, 1989, Reed, 2006; Zheng et al., 2006a). The findings of this study have revealed that inter-

Table 4. Descriptive statistics for efficiency scores

	Multimedia Group	Spatial Ability	Mean	Standard Deviation	N
Efficiency Scores	Syncronized	High	.39	.08	12
		Low	.26	.09	11

		Low	.24	.06	23
		Total	.29	.09	45

active multimedia supports mental representation. Further, synchronized interactive multimedia supports the cognitive functioning in problem solving by reducing cognitive load and facilitating information retrieval and maintenance. Since learners' abilities to solve problems are closely related to their perceptions, the ability to form a mental representation of the external world is critical to the problem solving process. Since the ability to *effectively* solve problems is affected by the availability of cognitive resources, the way to increase such cognitive resources by reducing the cognitive load is essential in facilitating an environment for successful problem solving. Based on the discussions above, we would like to advance several suggestions regarding the use of interactive multimedia in teaching and learning:

1. It is suggested that the use of interactive multimedia should be based on an understanding of the cognitive functions of interactive multimedia. That is, an understanding of the relationship between the attributes of interactive multimedia and the cognitive functions in learning.
2. It is suggested that the use of interactive multimedia should focus on how to optimally maximize the effects of input information such as auditory, visual, and kinesthetic information in teaching and learning, especially the impact of such input information on cognitive learning such as learners' mental representation of external objects.
3. It is suggested that the use of interactive multimedia should take into consideration the design factor as well as the impact of the design on learners' cognition, particularly learners' ability to reduce cognitive load and retrieve and maintain critical information in learning.

CONCLUSION

Teaching problem solving can be challenging to teachers. Oftentimes, such a challenge is not due to learners' lack of skills to solve problems but because of inappropriately designed media that may cause cognitive overload, which leaves little cognitive resource for learners to work on the problems. Studies have shown that the learner's ability to solve problems can be mediated by an inadequate cognitive resource in the working memory resulting from a cognitive overload (Mar-

cus et al., 1996; Mayer, 2001; Van Merrienboer et al., 2005). The findings of this study demonstrated that appropriately designed media such as interactive multimedia can improve learners' abilities to solve complex problems. Moreover, appropriately designed media can be complementary to individual differences. For example, interactive multimedia can improve the performance of low spatial ability learners in problem solving. One of the important findings of this study was that synchronized interactive multimedia was effective in reducing cognitive load and facilitating information retrieval and maintenance during the problem solving process.

The study is significant in that it investigated, for the first time, the cognitive functions of interactive multimedia, especially synchronized interactive multimedia in complex problem solving. It probed into the attributes of interactive multimedia and their relations with the cognitive functions of problem solving. Future study should examine the relationship between various interactive multimedia designs and their cognitive functions in learning. It is suggested that future study should expand to include what Snow (1996) described as conative domain and examine learners' self-efficacy in complex problem solving in an interactive multimedia environment.

KEY TERMS

Cognitive Load: According to cognitive load theory (CLT), three types of cognitive load exist: *intrinsic load*, *extraneous* or *ineffective load*, and *germane* or *effective load*. The *intrinsic cognitive load* refers to cognitive load that is induced by the structure and complexity of the instructional material. Usually, teachers or instructional designers can do little to influence the intrinsic cognitive load. The *extraneous cognitive load* refers to the cognitive load caused by the format and manner in which information is presented. For example, teachers may unwittingly increase learner's extraneous cognitive load by presenting materials that "require students to mentally integrate mutually referring, disparate sources of information" (Sweller et al., 1991, p. 353). Finally, the *germane cognitive load* refers to cognitive load that is induced by learners' efforts to process and comprehend the material. The goal of CLT is to increase this type of cognitive load so that the learner can have more cognitive resources available to solve problems (Brunken, Plass, & Leutner, 2003; Marcus et al., 1996).

The Dual Coding Theory: The dual coding theory describes the role of sensory inputs in information processing. According to the dual coding theory, different forms of information such as verbal, visual, and auditory information are registered through different channels (Paivio, 1986). For example, the auditory information is registered through the auditory channel and the visual information is registered through the visual channel. The auditory and visual information then interact with each other within the working memory to form a mental representation of the external world (Mayer, 2001). Paivio (1986) argued that learners learn better when information is presented through multiple sensory channels, rather than one channel only. Studies (see Mayer, 1997; Mayer et al., 1991; Mayer et al., 2003) show

that different presentation modes (i.e., words vs. pictures) and sensory modalities (i.e., audio vs. visual) may affect students' learning differently.

Interactive Multimedia: Interactive multimedia refers to the use of several media in learning where learners are able to process information through multiple sensory channels including auditory, visual, and kinesthetic manipulation. The advantages of interactive multimedia in learning include visualizing abstract and concrete ideas by creating images, diagrams, or animations, reducing cognitive load in learning, facilitating mental representation of external objects, and improving cognitive learning for low spatial ability learners.

Multiple Rule-Based Problems: Multiple rule-based problems refer to the type of problems that consist of problems, rules and conditions that are mutually restricting. The learner is to find an optimal solution by weighing the conditions and rules and at the same time make a decision that would meet the conditions or rules without conflicting each other. The multiple rule-based problem involves a complex, nonlinear thinking process where the learner reaches a solution by engaging in a series of cognitive thinking activities such as analyzing, synthesizing, and evaluating the information while holding the conditions and rules in mind within a short time framework provided by the working memory. Thus, multiple rule-based problem solving may require more working information than does causal relationship problem solving or single rule-based problem solving. The multiple rule-based problem solving is likely to increase intrinsic cognitive load more than other two types of problem solving.

Single Rule-Based Problems: Single rule-based problems refer to a type of problem that emphasizes causal relationship among entities. The single rule-based problem solving, according to Frye et al. (1995), focuses primarily on the cause and effect of events and requires straightforward deductive thinking such as applying the rule of card sorting to the action of sorting a deck of cards. Studies show that single rule-based problems may require less working information within the working memory and impose less cognitive load on learners than do multiple rule-based problems.

Visualization: Visualization refers to techniques used to communicate both abstract and concrete ideas by creating images, diagrams, or animations.Visualization has been defined as an important indicator of measuring learners' spacial ability. Its applications have expanded into science, engineering, education, medicine, etc. Typical applications of visualization include computer graphics, interactive multimedia, animations, and so forth.

Working Memory: Working memory is a theoretical framework that refers to the structures and processes used for temporarily storing and manipulating information. According to Baddeley and Hitch (1974), the working memory consists of two "slave systems" responsible for short-term maintenance of information, and a "central executive" responsible for the supervision of information integration and for coordinating the slave systems. One slave system, the articulatory loop, stores phonological information and prevents its decay by silently articulating its contents, thereby refreshing the information in a rehearsal loop. The other slave system, the visuo-spatial sketch pad, stores visual and spatial information. It can be used, for example, for constructing and manipulating visual images, and for the representation of mental maps. The sketch pad can be further broken down into a visual subsystem (dealing with, for instance, shape, color, and texture), and a spatial subsystem (dealing with location). The central executive system is, among other things, responsible for directing attention to relevant in-

formation, suppressing irrelevant information and inappropriate actions, and coordinating cognitive processes when more than one task must be done at the same time. Studies show that the working memory is very limited in both duration and capacity. The working memory typically stores about seven elements but normally operates on only two or three elements.

Chapter 5.17
Multimedia, Information Compexity and Cognitive Processing

Hayward P. Andres
Portland State University, USA

ABSTRACT

Organizations are faced with increasing costs needed to train employees in today's high technology environment. Educators are also striving to develop new training and teaching methods that will yield optimal learning transfer and complex skill acquisition. This study suggests that trainee/learner cognitive processing capacity, information presentation format and complexity, and multimedia technology should be leveraged in order to minimize training duration and costs and maximize knowledge transfer. It presents a causal model of how multimedia and information complexity interact to influence sustained attention, mental effort and information processing quality, all of which subsequently impact comprehension and learner confidence and satisfaction outcomes. Subjects read a text script, viewed an acetate overhead slide presentation containing text-with-graphics, or viewed a multimedia presentation depicting the greenhouse effect (low complexity) or photocopier operation (high complexity). Causal path analysis results indicated that presentation media (or format) had a direct impact on sustained attention, mental effort, information processing quality, comprehension, and learner confidence and satisfaction. Information complexity had direct effects on sustained attention, mental effort and information processing quality. Finally, comprehension and learner confidence and satisfaction were both influenced through an intervening sequence of sustained attention, mental effort and information processing quality.

INTRODUCTION

During information presentation, the target audience must construct a mental representation of situations or scenarios conveyed by the verbal content and images contained in the presentation. Cognitive psychologists refer to these representations as situation models (Friedman & Miyake,

2000). During situation model construction, increases in the number of alternative order of events, number of interconnections among objects and events, and factors that give rise to specific events will lead to a decline in the accuracy and capacity in cognitive processing utilized to construct a situation model (Zwaan, Magliano, & Graesser, 1995).

During multimedia presentation, subjects are presented with information in verbal and pictorial form, and both the verbal and visual processing channels of memory are used to translate the information into the appropriate situation model (Hegarty, Narayanan, & Freitas, 2002; Mayer & Moreno, 2002). In instructional settings, animation and other types of graphics that depict the behavior of various phenomena such as meteorology, physics, or chemistry have been used to reduce information complexity, augment cognitive processing, and facilitate comprehension (Moreno & Mayer, 2002; Rieber, 1991). Multimedia can also reduce the perceived equivocality of a low-analyzable decision-making task (Lim & Benbasat, 2000) and promote computer self-efficacy that leads to increased performance in computer-based training situations (Christoph, Schoenfeld & Tansky, 1998).

The goal of this study is to investigate the impact of multimedia information representation on cognitive processing activities (e.g., information encoding, situation model construction, and comprehension) typical to problem solving, training, and decision-making contexts. A capacity theory of comprehension (Just & Carpenter, 1992), dual processing theory of working memory (Mayer & Moreno, 2002; Paivio, 1986), theory of attentional inertia (Burns & Anderson, 1993), and the PASS (Planning, Attention, Simultaneous, and Successive) cognitive processing theory (Naglieri & Das, 1997) are used to provide a framework for this investigation.

The following section presents a review of empirical research on information presentation mode (i.e., format), information complexity, and cognitive processing. Next, using relevant research findings, a causal path model that presents hypothesized linkages among information presentation mode, information complexity, sustained attention and mental effort, information processing quality, comprehension, and learner confidence and satisfaction is presented. This is followed by a discussion of the findings, implications of results, and suggestions for future research on assessing multimedia-based information presentation on cognitive processing in learning, training, and decision-making settings.

BACKGROUND AND THEORETICAL FRAMEWORK

Information Presentation Media

Visual imagery depicts spatial arrangement, relative size, physical appearance, and the configuration of sub-components. Levin, Anglin, and Carney (1987) noted that pictures have the following effects: (1) minimize explanatory content by summarizing distinctive features or procedures; (2) facilitate interpretation by clarifying abstract concepts; (3) facilitate comprehension by eliminating the need to translate text into imagery; and (4) facilitate long-term memory by creating a memorable mnemonic. Mayer and Moreno (1998) noted that verbal (text or auditory) and visual information are each processed through distinct cognitive processing channels (i.e., verbal and visual) that compliment each other.

Multimedia utilizes computer and audio-visual technology to present information verbally (text or auditory), as static pictures or diagrams, and as animated graphics or video (Kozma, 1991). Attentional inertia (i.e., sustained attention and applied mental effort) results when a presentation medium induces perceptual arousal that sustains attention to the medium, and when learner confidence and satisfaction is promoted through enhanced cognitive processing (Burns & Anderson, 1993).

Information Complexity

Inferential complexity associated with information is a function of the number of causal links in a chain of actions, physical states, or mental states. Causal links between units of information are typically defined through the use of temporal (e.g., before, and then, after), causal (e.g., which caused, which enabled, because, if-then), or intentional (e.g., in order that, so that, to allow) connectives (Millis, Golding, & Baker, 1995). As the number of causal links needed to convey an idea or concept increases (i.e., causal chain length), working memory becomes overloaded because it is limited in the number of related ideas that can be simultaneously stored and processed (Halford, Wilson & Philips, 1998). Halford et al. (1998) noted that when working memory capacity is exceeded, subjects begin to condense the situation model to reduce cognitive load, but at the expense of making some relational information, that may be needed in subsequent processing, inaccessible. Information complexity is also a function of the extent to which one clause is related to more than one other clause–connective span (Millis, Graesser, & Haberlandt, 1993).

Cognitive Processing

The dual-coding theory of working memory suggests that information encoding and processing can take place in a verbal working memory and/or in a visual working memory workspace (Paivio, 1986). Comprehension is enhanced as a result of a reduction in cognitive load because the visual working memory workspace immediately encodes spatial information and does not require any translation of verbal information into imagery (Mayer & Moreno, 2002; Moreno & Mayer 2002). According to PASS cognitive processing theory, effective cognitive processing is controlled by an executive function responsible for selective attention, sustained attention, attentional switching, and mental effort, while encoding incoming verbal and/or spatial information and constructing the situation model (Naglieri & Das, 1997). Recent studies have suggested that greater human information processing and comprehension outcomes in complex sequential cognitive tasks are associated with increased mental effort or focused and directed concentration (Rende, Ramsberger & Miyake, 2002; Washburn & Putney, 2001; van Merrienboer, Schuurman, de Croock, & Paas, 2002).

Comprehension

The main contention of the capacity theory of comprehension is that cognitive capacity (e.g., short-term and long-term memory) facilitates or constrains computational (i.e., causal analysis of noun-verb clauses) and storage demands imposed in the construction of situation models (Just & Carpenter, 1992). Gordon, Hendrick, and Levine (2002) observed lower comprehension when subjects attempted to remember a short set of words while reading syntactically complex sentences. McElree (2000) suggested that information is maintained in working memory via a content-addressable mechanism and this information is periodically accessed to fill in gaps existing in the current situation model. Some studies have also shown that comprehension is also enhanced when information presentation takes place in multi-modal form (i.e., verbal, images, animation) thereby enhancing information processing by making use of the additive and synergistic properties of the verbal and visual working memory systems (Mayer & Chandler, 2001; Mayer & Moreno, 2002; Park, 1998).

Learning Satisfaction

Learning satisfaction has been described as a sense of accomplishment that learners feel at the conclusion of a learning event when the learning environment facilitated information processing that led to successful comprehension outcomes

(Keller, 1987; Song & Keller, 2001). In Keller's (1987) ARCS Model of Motivational Design, effective learning contexts exhibit four essential conditions – attention, relevance, confidence, and satisfaction. Learning satisfaction is highest when the information presentation arouses and maintains attention, curiosity and interest throughout the entire duration of the presentation. Further, attention is maintained when the instructional content is coherent and conveys relevant importance and meaningfulness to the learner. Finally, learning satisfaction arises from learner confidence that understanding of the content has been achieved and there is a positive correlation between learner mental effort and the extent of learning achievement (Keller, 1987; Small & Gluck, 1994). Self-reported learning satisfaction has also been associated with evaluations of the learning time and effort efficiency (Cole, 1992), willingness to learn more about the topic (Maki, Maki, Patterson & Whittaker, 2000), and perceived ease at learning (Hackman & Walker, 1990).

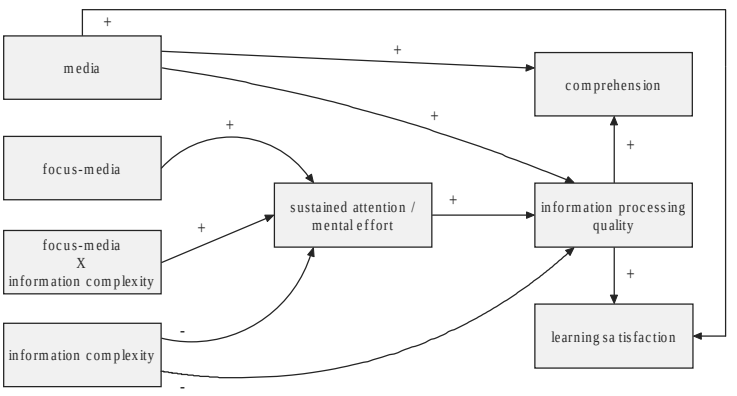
RESEARCH HYPOTHESES DEVELOPMENT

Figure 1 below graphically depicts the theoretical framework used in the formulation of the research hypotheses. In this study, the causal model presented suggests that information presentation media (i.e., text-only, graphics-and-text, and multimedia) and information complexity will each directly impact information processing quality (i.e., understandable, informative, interesting) and will interact to exert influences on the amount of sustained attention and mental effort applied in cognitive processing (i.e., situation model construction) of the information presented. Sustained attention and mental effort would then have an intervening influence on information processing quality. Finally, information processing quality would then impact comprehension and learning satisfaction outcomes.

Mental Effort

Cognitive processing of text-based information imposes a required involuntary demand for applied mental effort and sustained attention because sentences must be parsed to identify and extract

Figure 1: Impact of media and information complexity on information processing and comprehension outcomes.



noun-verb linkages representing concepts or ideas. Mental effort is then further extended when these concepts are placed into a situation model that is then mentally simulated for comprehension, verification, and self-correction. Alternatively, Burns and Anderson (1993) noted that increased sustained attention was associated with presentation media with the greatest sensory stimulation and appeal (i.e., dynamic visual and auditory stimuli). Sensory appeal and sustained attention were associated with the subjects' anticipation of forthcoming content. Therefore,

H1: *Text-based and multimedia information presentations, when compared to graphics with text information presentations, will lead to greater applied sustained attention and mental effort.*

Information complexity has also been associated with sustained attention and applied mental effort (Burns & Anderson, 1993). Content that is very difficult to encode and place into an appropriate situation model lowers sustained attention because the complex content is lower in intellective appeal, and the subject determines that applying continued attention and mental effort to forthcoming information will not be beneficial. Further, sustained attention and mental effort are inhibited when the subject's ability to understand the information presented is lowered by complex information (Christoph et al., 1998). Therefore,

H2: *As information content increases in complexity, subjects will expend less sustained attention and mental effort.*

Information presentation media and information complexity can interact to influence applied mental effort and sustained attention. As information complexity increased or the task required greater imagery or visualization, visual presentation reduced cognitive load through immediate encoding (Burns & Anderson, 1993). In addition, the sensory features of multimedia such as visual complexity, movement, and sound effects created an "audio-visual momentum" that led to perceptual arousal, which subsequently induced sustained attention and mental effort (Burns & Anderson, 1993). The "audio-visual momentum" reduces the tendency to withdraw attention and mental effort typically associated with the presentation of complex information. Therefore,

H3: *As information complexity increases (decreases), text-only and multimedia information presentations will lead to greater (lesser) sustained attention and mental effort when compared to graphics-with-text information presentations.*

Information Processing Quality

Mayer and Moreno (1998) noted that when using multimedia, subjects were able to integrate words and pictorial animation of lightening formation more easily when the words supplementing the animation were presented auditorily as opposed to written text. The encoding of the auditory/animation information presentation was more efficient because the subjects were able to maintain complete visual attention on the animation while simultaneously attending to the narration content. In contrast, the animation/text group experienced diminished cognitive processing due to a "split-attention" effect (i.e., required alternating shifts of visual focus between text processing and visual imagery processing). Therefore,

H4: *As information presentation format increases in modality (i.e., from text-only to graphics-with-text to multimedia), subjects will experience greater information processing quality.*

Rieber's (1991) study comparing static graphics versus animated graphics observed better knowledge extraction with animated graphics and, when given a choice to return to either presentation format, subjects overwhelmingly preferred the animated graphics presentation. The subjects in

Rieber's (1991) study exhibited attentional inertia (i.e., sustained attention and applied mental effort) when viewing the animated graphic presentation. The subjects found the multimedia presentation intellectually appealing, easier to understand, and more interesting. In addition, increased information processing quality was evidenced by the fact that the subjects viewing animation were able to acquire incidental knowledge when making inferences from imagery than with text-based propositions constructed from static graphics. Therefore,

H5: *An increase in sustained attention and mental effort will lead to greater information processing quality.*

Information complexity can directly influence information processing quality through an imposed increase in cognitive load. Long causal chain length can create difficulty in acquiring local coherence within a situation model and extensive hierarchical connections and high connective spans among related concepts can create difficulty in acquiring global coherence. Friedman and Miyake (2000) noted that casual connectives with long causal chains or high connective span temporarily suspended purging of the working memory in attempts to construct a complete and coherent situation model. Failure to purge working memory caused working memory overload. Consequently,

H6: *As information complexity increases, subjects will experience lower information processing quality.*

Comprehension and Learning Satisfaction

Information processing quality mediates comprehension because multimedia can lead to a reduction of complexity and increased cognitive processing capacity by targeting both verbal and visual working memory channels, thereby making the information presented more understandable, interesting, and informative. Alternatively, because of its linear structure, a text presentation that is structurally equivalent (i.e., equality in the setting, characters and/or objects, conceptual content, and episodic structure) to a static image with supporting verbal information or multimedia presentation will require more cognitive processing capacity to process (Mayer & Moreno, 1998, 2002). This suggests the following hypothesis.

H7: *As information processing quality increases, subjects will experience greater comprehension.*

In the comparison of text, narration, and graphics with text, Mousavi, Low, and Sweller (1995) found that a combined text and graphics presentation reduced the cognitive load in solving geometry problems resulting in superior learning. The graphics depicting the geometric problem space clarified the abstract equation representation; this enabled timely solution to the problem. Cassady (1998) noted that, compared to traditional lecture presentations, students found multimedia-based presentations to be superior in the following areas: (1) flow, organization, and understandability of the information presented; (2) ease in following the presentation; (3) ability to pay attention to the presentation; and (4) interest in the information presented. Therefore,

H8: *As information presentation format increases in modality (i.e., from text-only to graphics-with-text to multimedia), subjects will experience greater comprehension.*

Towler and Dipboye (2001) observed superior training outcomes when the training presentation was characterized as higher in coherent organization and trainer expressiveness. Effective training presentations provided clarifying and elaborative content and commanded sustained

attention through appropriate vocal intonations that acted as cues that made the presentation easy to follow. The trainees also displayed greater positive affect, information recall and comprehension, and perceptions that they could apply what they learned to actual task execution and problem solving. After 12 weeks of study and practice in an introductory programming class, Ramalingam and Wiedenbeck (1998) observed an increase in subject-perceived computer-programming learning achievement. Consequently,

H9: *As information processing quality increases, subjects will experience greater learning satisfaction.*

H10: *As information presentation format increases in modality (i.e., from text-only to graphics-with-text to multimedia), subjects will experience greater learning satisfaction.*

RESEARCH METHODOLOGY

Participants

Seventy-eight male and female undergraduate students voluntarily participated in the experiment. Each subject was eligible to participate in a lottery of five drawings of fifty dollars. The average age was 25 years (*SD = 5.39*).

Materials

Two text passages, *Photocopier Operation* (high information complexity) and *GreenHouse Effect* (low information complexity), with relatively equal readability scores were utilized. Every attempt was made to keep the following factors as constant as possible between the passages: text length, Flesch Reading Ease, and Flesch-Kincaid Reading Grade Level (Wagenaar, Schreuder, & Wijlhuizen, 1987). The Flesch Reading Ease statistic is calculated by multiplying the average sentence length by 1.015, multiplying the number of syllables per 100 words by .846, and then the sum of these products is subtracted from 206.835. The Flesch-Kincaid Reading Grade level statistic is calculated by adding the average sentence length to the percentage of long words (i.e., more than two syllables), and the sum is then multiplied with 0.4. Table 1 details specific readability scores.

For complexity, the passages differed in causal chain lengths and the extent to which one clause was causally related to other clauses throughout other parts of the scenario (i.e., connective span). Connective span was computed as the number of causal relationships each idea unit had with other idea units within the same sentence and across sentences throughout the text. The Greenhouse Effect and Photocopier Operation, respectively, had 9 and 18 idea units with a connective span of three and 10 and 29 sentences with direct contigu-

Table 1: Passage Readability Measures

Readability Measure	**Photocopier Operation**	**GreenHouse Effect**
Paragraphs	14	12
Sentences (words/sentence)	8 6 (19.6) 8	5 (16.8)
Flesch Reading Ease	44.8 4	0.7
Flesch-Kincaid Grade Level	11.8	11.7

ous causal links greater than one. The connective span and direct causal links values indicated that the Photocopier Operation passage was higher in information complexity than the Greenhouse Effect passage.

The overhead slides and multimedia presentations were both equivalent in overall content (i.e., idea units expressed) and episodic structure (i.e., sequence of events) to the text passages (Baggett, 1979). The overhead-slides presentation utilized static diagrams that illustrated components involved in photocopier operation or elements involved in greenhouse gas generation. The multimedia presentation animated the elements contained in the static diagrams used in the overhead presentation.

Procedure

Path analysis was the chosen as the data analysis procedure because analysis of variance is not particularly well suited for testing direct, mediating and intervening relationships among a set of variables. Each subject was randomly assigned to one of the media (i.e., text-only, text with graphics, or multimedia) and complexity conditions (i.e., high or low information complexity). The overhead slides sessions presented the same conceptual content using static overheads composed of graphs and pictures supplemented with text. Subjects in the computer-based multimedia presentation sessions watched a series of PowerPoint slides that contained animated graphs and images along with supporting text. All sessions (text-only, text-with-graphics overhead slides, and multimedia) were executed for a duration of 12 minutes. After each session, the subjects completed a Likert-type questionnaire that elicited perceptions of the amount of sustained attention/mental effort, information processing quality, and learning satisfaction. Following this, they were administered a timed comprehension test composed of short essay questions.

Measures

Information Presentation Media. Presentation media (i.e., text-only, text-with-graphics, or multimedia) was coded using two contrast code variables (Pedhazur, 1997). The first contrast code variable, *media*, contrasted group mean outcomes of each of the three presentation modes (i.e., text-only, text-with-graphics, and multimedia). The second contrast code variable, *focus-media*, contrasted the group means of text-only and multimedia combined against the mean of the text-with-graphics group.

Information Complexity. Information complexity was operationalized as a function of connective span (i.e., the number of causal relationships each idea unit had with other idea units within the same sentence and across sentences throughout the text) and causal chain length (i.e., number of contiguous causal connections). The Photocopier Operation content was greater in information complexity than the Greenhouse Effect content. Information complexity was contrast coded. Grade Reading Level scores for both passages were similar in value in order to restrict complexity to connective span and causal chain length (see Table 1) and to minimize confounding from differences in domain content.

Sustained Attention/Mental Effort. The sustained attention/mental effort scale (Likert-type) was developed using Burns and Anderson's (1993) theory of attentional inertia. The sustained attention scale elicited self-perceptions regarding sustained looks at and concentration on the presentation. The scale reliability (Cronbach's alpha) for the sustained attention/mental effort scale was .78.

Information Processing Quality. Perceived information processing quality was assessed using questionnaire items (semantic differential and Likert-type items) adapted from Buchheit (1996). The perceived information processing quality elicited an assessment of the perceived

interestingness, understandability, and informativeness of the presentation. The scale reliability (Cronbach's alpha) for the information processing quality scale was .90.

Comprehension. In order to facilitate objective scoring, the short essay questions were constructed and scored according to the analytic approach of essay assessment (Jacobs & Chase, 1992; Linn & Gronlund, 2000). The Photocopier Operation and Greenhouse Effect comprehension tests each required 13 correct responses. Sample comprehension questions are: "How is the electrostatic image formed on a photoconductor's drum surface?" and "How does livestock production lead to an increase in global warming?"

Learning Satisfaction. The learning satisfaction scale (Likert-type) was developed using Keller's (1987) ARCS Model of Motivational Design of effective learning environments. The learning satisfaction scale elicited self-perceptions regarding extent of comprehension and understanding of the information presented, sense of mastery to use the information presented, usefulness of the information presented, and desire to learn more about the information topic. The scale reliability (Cronbach's alpha) for the learning satisfaction scale was .84.

RESULTS

A series of regression analyses was chosen as the data-analytic strategy for testing the proposed causal path model depicted in Figure 1 (Pedhazur, 1997). Problem solving ability (i.e., grade point average) was considered as a covariate to comprehension but there was no significant bivariate correlation. The overall results from the series of regression analyses used to test the fit of the causal model to the data are summarized in Figure 2. Table 2 presents the means, standard deviations, original correlations, and reproduced correlations of the variables in the study.

The path coefficients (see Figure 2) were used to compute the reproduced correlation of variables (see upper half of matrix in Table 2) that are interconnected through direct and indirect causal paths (Pedhazur, 1997). The total variance explained by the causal path model was 0.927. A root mean squared residual (RMR) of 0.076 and a normed fit index (NFI) of 0.822 suggest that the model provides a good fit to the data (Gerbing & Anderson, 1993; Pedhazur, 1997).

The original correlations are reported in the lower half of the matrix. The reproduced correlations of relevant variables are reported in the upper half of the matrix.

Sustained Attention and Mental Effort

As posited in Hypothesis 1, the text-only and multimedia groups (i.e., focus-media) did exhibit a positive increase in sustained attention and mental effort (standardized beta = .26, $p < .05$). Increases in information complexity lowered the motivation to maintain sustained and effortful processing of the information presented (standardized beta = -.23, $p < .01$) thereby supporting Hypothesis 2. Hypothesis 3 predicted that text-only and multimedia presentations would positively moderate the tendency for increases in information complexity to lead to withdrawal of sustained attention and mental effort as compared to text-with-graphics presentations. The results indicated that Hypothesis 3 was supported (standardized beta = .23, $p < .05$).

Information Processing Quality

The results indicated support for Hypothesis 4 and suggest that presentations that target both the verbal and visual working memory channels are perceived to be more understandable, informative, and interesting (standardized beta = .18, $p <$. 05). The results for Hypothesis 5 indicated that sustained attention and applied mental effort is positively correlated with information processing quality (standardized beta = .62, $p <$ .01). For Hypothesis 6, the results indicated that information complexity was negatively related to information processing quality (standardized beta = -.34, $p < .01$).

Comprehension and Learning Satisfaction

For Hypothesis 7, the results indicated that information processing quality was positively related to comprehension (standardized beta = .39, $p <$ .01). As suggested in Hypothesis 8, increased comprehension was associated with increased presentation modality (standardized beta = .23, $p < .05$). The results also indicated that increased information processing quality was positively related to learning satisfaction (i.e., perceived understanding and mastery of the topic). Consequently, Hypothesis 9 was supported (standardized beta = .81, $p < .01$). Finally, hypothesis 10 predicted that increases in media modality would be positively related to greater sense of mastery of use of the information acquired (i.e., learning satisfaction). The results indicated support for Hypothesis 10 (standardized beta = .15, $p < .05$).

DISCUSSION

The path coefficient between sustained attention and focus-media interaction with information

complexity (beta = .23) was only slightly lower than the path coefficient between sustained attention and focus–media alone (beta = .26). These results suggest that adverse effects on sustained attention (Burns & Anderson, 1993) typically associated with information complexity (beta = -.23) were moderated by increased media modality. Apparently, the multimedia group subjects recalled more accurate details regarding sequence of operation and dependency among photocopier components or the process of greenhouse gas generation. Further, the results suggest that multimedia did not create a split attention situation (i.e., cognitive load due to switching attention between text and visual content) typically observed in text-with-graphics presentations. This supports the major tenet of dual coding theory (Paivio, 1986); the verbal/auditory and visual memory channels actually augmented each other.

The direct effect of media on comprehension (beta = .23) supported the contention that verbal and visual working memory effects are additive and synergistic. Sustained attention exhibited a greater association with information processing quality (beta = .62) as compared to media (beta = .23). Apparently, media's role in inducing and maintaining attention was more important to information processing quality than its role in targeting both the verbal and working memory channels. Media modality was related to learning satisfaction (beta = .15) but information processing quality imposed greater relative variation (beta = .81). It is clear that sustained attention, associated with focus media, was essential for positive information processing quality needed to enhance both comprehension and learning satisfaction.

The positive relationship between focus-media (i.e., text-only and multimedia) and sustained attention and mental effort support previous findings that text-only presentations impose a required cognitive processing effort while multimedia induced voluntary attention and mental effort (Andres, 2001; Kozma, 1991). Sustained attention and mental effort was highest for the text-only group (mean = 20.25), followed by multimedia (mean = 19.27), followed by text-with-graphics (mean = 17.08). The text-only group reported higher levels of attention and mental effort, which was likely expended to encode the information (i.e., identify noun-verb linkages and to establish local and global coherence among related clauses). Here, focus and considerable mental effort are needed to translate text into a visual simulation. There is less potential to be distracted from external stimuli under such periods of high concentration. In contrast, multimedia appeared to generate higher sustained attention through the sensory appeal of its multi-modal content (i.e., text, images, narration, and animation).

The results indicate that high information complexity was second to sustained attention in its magnitude of explained variation in information processing quality (beta = -.34). The negative association of information complexity with information processing quality is evidence that there were considerable information processing errors in identifying idea units (noun-verb linkages) and establishing causal connections among idea units to create a situation model. This result supports the "cognitive resource allocation" perspective proposed by Millis et al. (1993). According to the resource allocation perspective, the presence of excessive causal connectives and high connective spans creates ambiguities in the encoding and interpretation of incoming information. This overloaded working memory and diminished information processing quality and subsequently comprehension and learning satisfaction. The results also indicate that magnitude of relationship between information complexity (beta = -23) and focus-media (beta = .26) are fairly equal but opposite in direction. This suggests that competing external stimuli or disinterest can possibly distract a subject when comprehensibility of information is difficult. In addition, high local and global connections among concepts result in minimal situation model simulation accuracy, greater sense of confusion, and greater disinterest in presentation content.

A review of relevant literature suggested that the interaction term, focus media x information complexity, should be included in the model. As stated earlier, focus-media (i.e., text-only and multimedia) has a tendency to command greater required (e.g., text parsing) or voluntary (e.g., perceptual arousal) sustained attention and mental effort. In contrast, increased complexity has the potential to lead to withdrawal of sustained attention and mental effort through incomprehensibility and disinterest in the information presented. The results for Hypothesis 3 suggest that both the encoding process (e.g., verbal vs. verbal & visual) and semantic structure of information (i.e., causal chain length and connective span) interact in the determination of effort to encode incoming information. Apparently, the semantic structure of information should drive information presentation format decisions.

IMPLICATIONS AND CONCLUSIONS

The results indicated implications for the use of computer-based instruction, meeting presentations, and computer-supported decision-making contexts. It is clear that multimedia provides a unique opportunity to examine the nature of human information processing (i.e., encoding, situation model construction, and situation model simulation) and how information processing interacts with information format and information complexity. The ability of multimedia to target both the verbal and visual working memory channels affords the opportunity to create experimental tasks that can be used to assess cognitive processing limitations. Apparently, increasing presentation modality can minimize the occurrence of excessive cognitive load when processing complex information. Multimedia-based visuals supported by text and/or narration can convey a maximum amount of information that is processed more efficiently than static images and text.

Information content should be organized so as to minimize local and global causal dependencies among concepts. Instructional and training presentations should be examined to identify what content is best suited for a specific presentation modality. Such decisions would be driven by the complexity of the topic, the extent of mental model construction and simulation required to understand the topic (i.e., abstract level), and the extent to which information processing requires greater short-term memory capacity and/or long-term memory capacity. In decision-making contexts, subjects must often analyze data, construct mental models of alternative solutions, simulate these alternative models as potential scenarios, and finally compare the outcomes of each simulation against a set of decision-making criteria. In engineering contexts (e.g., mechanical or chemical), multimedia can be used to depict physical models that represent abstract models defined by mathematical equations. It is clear that multimedia can be applied in such contexts with the aim of reducing cognitive load through the provision of graphs, imagery, and animation that summarize data physical form, and motion.

Past research on multimedia use has noted that there can be negative outcomes during multimedia use. Split-attention effect (i.e., the need to integrate information from two different sources – text and diagrams) has been observed in some multimedia studies. Split-attention was not observed in this study, and it is believed that split-attention can be avoided through careful embedding of text onto or nearby the related images. Further, some research studies on presentation mode and cognitive processing outcomes have observed mixed results regarding effectiveness of increased presentation modality. These mixed results could possibly be attributed to inconsistencies in the experimental task used (e.g., word recognition, word-image associations, short passages, minimal information complexity). In an attempt to isolate presentation/instructional media effects, presentation content across media

(i.e., text-only, overhead slides, multimedia) was structurally equivalent in idea units expressed and sequence of events. Information complexity was limited to the causal chain lengths, and local and global connections of idea units (i.e., connective span) needed to describe the *Greenhouse Effect* or *Photocopier Operation*. Readability scores were essentially equivalent.

A limitation of the current study is the use of self-reported measures for sustained attention and mental effort and information processing quality. Objective measures of sustained attention would offer greater internal validity. Future studies should attempt the use of objective measures of attention and applied mental effort. Although larger and more realistic than tasks previously utilized, this study's task can be viewed as a limitation to the study. Future studies should extend the length and complexity of the tasks in order to afford greater generalizability. Finally, the use of a laboratory study offers greater internal validity, but its use can be viewed as a limitation because field studies offer more external validity. The ability to take advantage of the power of computer-based technologies such as multimedia will depend on continued research aimed at understanding the relationship between the capabilities of the technology and information processing requirements of the task to be supported with the technology.

Chapter 5.18
Interface Design, Emotions, and Multimedia Learning

Chaoyan Dong
New York University, USA

ABSTRACT

In social psychology, "what is attractive is good" means that a physically attractive person is perceived to be more favorable and capable. In industrial design, the interface is one of the three elements that influence users' experience with a product. For multimedia learning, does the interface design affect users' experience with learning environments? Does attractive interface enhance multimedia learning? Research in multimedia learning has been neglecting this issue. In this chapter, I propose that attractive interface design does indeed promote multimedia learning. This hypothesis is based on the review of the following theories and related empirical studies: (1) an interface impacts a user's experience; (2) beautiful interface induces positive emotions; (3) positive emotions broaden cognitive resources; and (4) expanded cognitive resources promote learning. The model of emotional design in multimedia learning is proposed to highlight how emotions regulate multimedia learning. Suggestions regarding designing attractive interfaces are provided.

INTRODUCTION

Multimedia learning refers to learning from multimedia design, which is the presentation of materials both in words and pictures. Multimedia design has been widely used in educational settings. Research on multimedia learning has been looking at how to design effective and efficient multimedia environments. For example, in *multimedia learning*, thus far the most comprehensive research on multimedia learning, Mayer (2001) summarizes seven multimedia learning principles, that is, spatial contiguity principle, multimedia principle, temporal contiguity principle, coherence principle, modality principle, redundancy principle, and individual difference principle. All of these principles are about the design of text, audio, and video, each of which is assumed to be a multimedia design element that determines the results of multimedia learning. Unfortunately, the assumption is only partially true when the design is always for one group of learners. In reality, the idea of "one size fits all" probably never works. It is critical to consider the roles of both multimedia

designers and learners when talking about the quality of multimedia learning.

Multimedia designers determine interface design in addition to texts, audio, and video. Interface design refers to designing the interaction between a human and a machine (Raskin, 2000). The interface design induces certain emotions from users while they interact with the design. In other words, interface design is the visible surface that users experience while interacting with a design, while emotions are the underlying, invisible media between the users and the design. Research on emotions indicates that emotions play as important a role as cognition does in learning. It is widely agreed that positive emotions enhance cognitive activities, although the cognitive activities do not necessarily entail learning or multimedia learning. Therefore, when talking about the quality of multimedia learning, we must address the issue of how the interface design affects multimedia learning and should consider the emotions induced from experiencing the multimedia design. The discussion in this chapter helps to identify interface design and emotions as influences in multimedia design that is not subsumed by the influences on efficiency and effectiveness that have traditionally been researched by multimedia learning theorists.

The following section explains the theoretical framework of how interface design affects users' experience as well as their emotional states, especially how positive emotions influence cognition, and how changes in cognition regulate multimedia learning. Based on the theoretical framework, the emotional design model in multimedia learning is proposed, which is the main focus of the chapter. Since positive emotions facilitate cognitive activities, as suggested by the theoretical framework, design features that intend to induce positive emotions are discussed. Future trends in research of emotional design in multimedia learning are also discussed.

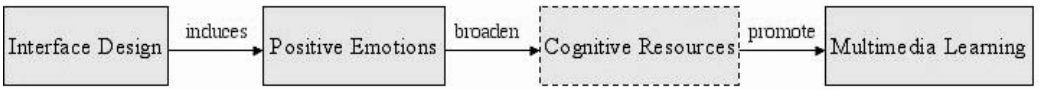
BACKGROUND

Interface design is the first thing users experience when interacting with a multimedia design. Emotions are induced before initiation of cognitive activities to process in users' brains. In other words, interacting with the interface design induces emotions and also activates cognitive activities from users. Emotional change is a rapid activity, preceding the cognitive activities. Norman's (2004) theory of emotional design proposes a theoretical framework to explain how to interact with an interface design affects users' emotions, and also suggests that attractive designs induce positive emotions from users. Fredrickson's (1998) positive emotion theory elucidates how positive emotions facilitate cognitive activities. The goal for multimedia learning research is to make the learning effective and efficient. We should ask, Do positive emotions promote multimedia learning? Mayer's cognitive theory of multimedia learning explains the general process of multimedia learning. One of Mayer's assumptions is that the working memory has a limited capacity, but he does not consider the possibility that positive emotions broaden cognitive resources. Does it mean that positive emotions promote multimedia learning by expanding the working memory capacity? The discussion is illustrated in Figure 1 by connecting the four theories, which are combined to form the conceptual framework for the chapter. The details of each theory and the connections between these theories are explained in the following section.

How Does the Interface Design Affect Users' Experience?

Norman (2004) proposes a framework to describe what happens when users interact with a design. According to Norman, a product presents three aspects to its users: its attractiveness, its usability, and the reflective images. The three features induce different emotions from users. Attractiveness

Figure 1. The conceptual framework



is a result of the visceral level activity in the brain. Visceral activity is a "rapid, reactive response to appearance" (Norman, p. 21), and induces taste-based emotions from users (e.g., attractiveness or unattractiveness). Norman suggests that the visceral design be developed to match the visceral activity in the brain. Visceral design is the design of a product's appearance and feel. Usability is determined by the brain level that processes everyday behaviors. Usability induces goal-based emotions (e.g., satisfaction, distress, optimistic expectation, worry, relief, frustration, and disappointment). Behavioral design concerns how easy the design is to use. Experimental studies (Kurosu & Kashimura, 1995; Tractinsky, 1997; Tractinsky, Katz, & Ikar, 2000) indicate that interface aesthetics could really be important and positively impact the perceived usability of a design. The reflective image is the result of reflective activity in the brain. Reflectivity induces standard-based emotions such as admiration, gratitude, pride, anger, and resentment.

Ortony's (2003) theory is similar to Norman's in the sense that both are based on a framework that explains users' interaction with a design. The key difference is that Ortony puts more emphasis on the factors that induce users' emotions while interacting with a product. He points out that the designers' motivation in designing a product also determines users' emotions in addition to the users' approach. He categorizes designers' motivation as indifference, prevention, and promotion. When designers are indifferent, it is possible that no emotions will be induced from users, except perhaps by accident; Ortony does not include emotions induced by accident in his theory. When designers aim for prevention, the product will probably not induce emotions from users, as these are the result of design. It is when designers aim for promotion that the product is most likely to induce emotions from users, in this case by design.

In summary, both Norman (2004) and Ortony (2003) suggest that the interface design induces emotions from users. Experimental studies are available to support the argument (Klein, Moon, & Picard, 2002; Kurosu et al., 1995; Lester et al., 1997; Tractinsky, 1997; Tractinsky, Katz & Ikar, 2000). For example, Desmet (2002) defines 41 design-related emotions and the factors that elicit these emotions. Attractiveness, one of the design-related emotions, is induced by one specific feature of the interface or by the overall appearance. The underlying assumption is that attractive interface induces positive emotions, which is consolidated in his later research.

What is Attractive is Good?

Attractiveness in daily language corresponds to aesthetics in philosophy, so a design that represents fun, cuteness, and includes color may be considered aesthetic if the user likes it. Since experiencing a multimedia design induces certain emotions from users, does attractive interface design induce positive emotions from users as suggested by Norman's (2004) theory? LeDoux (1982) proposes a dual-processing theory for visual images. After a visual design registers in the brain, it is processed either in the format of unconscious emotions or in a detailed perceptual analysis. Both processes happen in two different regions of the brain, that is, the thalamo-amygdala pathway and the cortical pathway. It means that a

visual design induces both emotional responses and cognitive activities in the brain. On the other hand, research on visual design indicates that users form the emotional state of "like" while considering a design as attractive. "Like" is one category of positive emotions. This phenomenon is supported by the implicit personality theory in social psychology (Schneider, 1973), which explains how human beings perceive other people. The assumption of the theory is that human beings are "naïve scientists" actively perceiving their surroundings. The process of perceiving other people includes describing the attributes of personality that an individual believes others to possess, predicting the relations between these attributes, and explaining why one person behaves in certain ways. The prediction of the theory is that physically attractive people are believed to be more capable (Ashmore, 1981; Dion, Berscheid, & Walster, 1972; Eagly, Ashmore, Makhijani, & Longo, 1991). It conforms to Norman's (2004) proposition that attractive appearances induce positive emotions. In summary, the dual-processing theory for visual images, the research on visual design and the implicit personality theory, collectively indicate that attractive interface design induces positive emotions in users, which is supported by experimental studies. For example, Schenkman and Jonsson (2000) discover that people prefer aesthetically pleasing Web sites, which induce positive emotions from users. Yamamoto and Lambert (1994) investigate how a product's aesthetics impacts users' evaluation of industrial products and find that product appearance has a moderate impact on customers' preference. Jordan's (1998) study indicates that the aesthetically pleasing products induce positive emotions; participants will use more aesthetically pleasing products than those unattractive products. Lavie and Tractinsky (2004) suggest that "the visual aesthetics of computer interfaces is a strong determinant of users' satisfaction and pleasure" (p. 269). Van der Heijden's (2003) study concludes that the perceived visual attractiveness of the interface positively impacts users' attitudes and intention toward a design, which positively impacts actual usage. Demirbilek and Sener (2001) review literature on product design and emotions and conclude that certain design elements (i.e., fun, cuteness, familiarity, metonymy, and color) induce positive emotions from users. These findings are confirmed in a later experimental study by Demirbilek and Sener (2003).

Positive Emotions

Attractive design induces positive emotions from users, but how are positive emotions defined? And how do positive emotions impact cognition? Positive emotions are a category of emotions, sharing features identified by the following theories on emotions: emotions refer to mental states (Cornelius, 1996). The cognitive perspective of emotions focuses on the role that thought plays in the process of emotions (Arnold, 1960; Frijda, 1986; Lazarus, 1991; Oatley, 1992; Oatley & Johnson-Laird, 1987; Zajonc, 1980). Smith and Lazarus (1993) propose a cognitive-motivational relational theory, which claims that emotions are preceded by appraisal triggered by specific environments and related to an individual's experience. Positive emotions are not simply the opposite of negative emotions (e.g., that happiness and sadness are controlled by independent neural pathways) (George et al., 1995). A growing body of empirical evidence shows that positive and negative emotions have qualitatively different information-processing models (Gray, 2001; Isen, 1999; Kuhl, 1983, 2000). Therefore, positive emotions and negative emotions play different roles in cognitive processes, with positive emotions playing a particularly important role (Diener & Larsen, 1993; Myers & Diener, 1995). Fredrickson's (1998) broaden-and-build theory of positive emotions provides a framework for understanding how positive emotions impact cognitive processes. According to Fredrickson, positive emotions broaden the thought-action repertoire. Specifically, positive emotions broaden

the scope of attention, cognition, and action, as well as building physical, intellectual, and social resources. The outcome of the broadened thought-action repertoires is an increase in physical, intellectual, and social resources. The increase in these resources as a result of experiencing positive emotions is stable, outlasting the transient emotional states. Fredrickson defines the contexts that induce positive emotions as safety and satiation. Fredrickson's theory is supported by Isen and her colleagues' experimental studies on positive emotions. These demonstrate positive emotions linked to an increase in brain dopamine levels, so the authors conclude that "the elevated dopamine levels influence performance on a variety of cognitive tasks" (Ashby, Isen, & Turken, 1999, p. 544).

A large amount of research has shown convincingly that positive emotions systematically influence performance on many cognitive tasks, which supports Fredrickson's statement that positive emotions promote cognitive activities. For example, positive emotions improve creative problem solving (Estrada, Isen, & Young, 1994; Greene & Noice, 1988, Isen, Daubman, & Nowicki, 1987), enhance recall of study material (Isen, Shalker, Clark, & Karp, 1978; Lee & Sternthal, 1999), and systematically change strategies used in decision-making tasks (Carnevale & Isen, 1986; Estrada, Isen, & Young, 1997). Bolt, Cogschke, and Kuhl's (2003) study indicates that positive emotions improve participants' judgments. Fredrickson and Branigan's (2005) study validates the broaden-and-build theory that positive emotions broaden the scope of attention and thought-action repertoires, whereas negative emotions narrowed thought-action repertoires. Gasper (2004) tests the level of focus hypothesis proposed by Fredrickson (1998) that a happy person is more likely to process stimuli as a whole. The results suggest that happier individuals process information more globally than do those in negative moods.

In summary, positive emotions generally promote cognitive activities, and interacting with attractive interface design induces positive emotions from users. How do in particular positive emotions promote learning from multimedia? Before answering the questions, let us first review Mayer's (2000) cognitive theory of multimedia learning, which explains how multimedia learning happens.

Mayer's Cognitive Theory of Multimedia Learning

Three assumptions are employed for the theory, that is, the dual-channel assumption, the limited-capacity assumption, and the active-processing assumption. The dual-channel assumption states that the sensory modes for information input include two channels: ears processing verbal information and eyes for pictorial information. The limited-capacity assumption is closely related to the model of working memory by Baddeley (1986, 1992, 1999) and the cognitive load theory by Chandler and Sweller (1991; Sweller, 1999). The limited-capacity assumption states that the amount of information processed by each channel at one time is limited. According to Miller (1956), the average amount of information processed at each channel at one time is five to nine chunks. The active-processing assumption proposes how the human brain processes information, that is, selecting information, organizing the incoming information, and integrating the information with other knowledge stored in the long-term memory. Based on the three assumptions, the cognitive theory of multimedia learning proposes that multimedia information is presented in two formats, words, and pictures. Verbal information enters working memory through the ears, while visual information enters working memory through the eyes. In working memory, verbal information interacts with visual information, and the information is organized into either verbal models or pictorial models. The verbal models and the pictorial models are integrated with individual's prior knowledge of the specific topic. In long-term

memory, the integrated information from verbal model, pictorial model, and prior knowledge is formed as schemata and stored in long-term memory. The cognitive theory of multimedia learning is supported by numerous experimental studies by Mayer and his colleagues (Harp & Mayer, 1997; Mayer, 1996, 1997; Mayer & Anderson, 1991; Mayer & Gallini, 1990; Mayer & Sim, 1994; Moreno & Mayer, 1999).

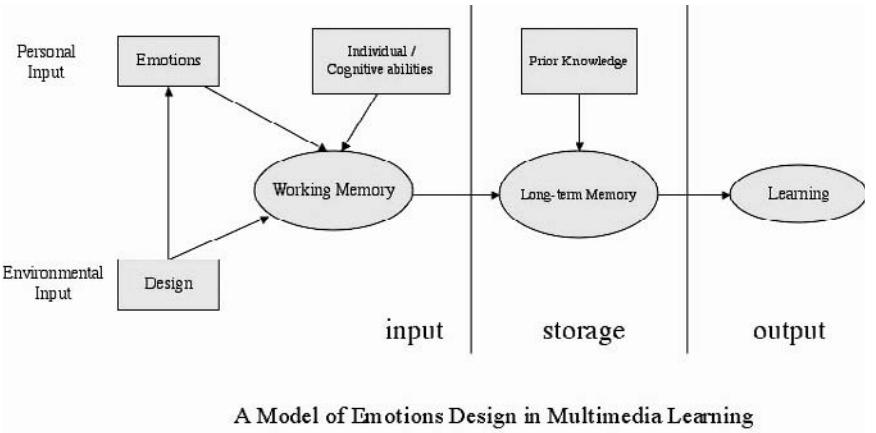
According to Mayer (2001), the capacity of the working memory and the capacity of both auditory and visual channels are limited. Fredrickson (1998) explains that positive emotions broaden the cognitive resources. However, she does not explain whether cognitive resources are related to the capacity of working memory. Further research is needed to verify whether positive emotions expand working memory capacities and whether positive emotions promote multimedia learning like that positive emotions do with other cognitive activities. One possible interpretation is that positive emotions increase the cognitive capacity and the working memory, which results in improved learning. The second possible interpretation is that the increased cognitive resources increase the amount of information processed in the working memory, which finally promotes learning. In summary, the four theoretical perspectives indicate that an attractive interface should promote multimedia learning.

MODEL OF EMOTIONAL DESIGN IN MULTIMEDIA LEARNING

The four theories presented previously provide insight into the cognitive mechanisms underlying how attractive design affects multimedia learning through positive emotions. Based on the preceding discussion, we introduce the model of emotional design in multimedia learning, a framework for integrating emotions into a multimedia learning environment. Later the implications of the model for multimedia design are discussed.

The model of emotional design in multimedia learning is intended to highlight the impact of emotions on multimedia leaning (see Figure 2). The model is built on three previous theories (i.e., the information-processing theory in cognitive psychology (Miller, 1956), the cognitive theory of emotions (Arnold, 1960), and the cognitive theory of multimedia learning (Mayer, 2001)). The information-processing theory proposes that the structure of human cognition includes both information input and output systems. Information input includes learners' input and environmental

Figure 2. A model of emotions design in multimedia learning



input. The environmental input refers to the multimedia design (Norman, 2004). Personal input includes the emotions that are induced from multimedia design, individual/cognitive abilities, and prior knowledge. Arnold claims that the sequence of emotional processes is as follow: perception → appraisal → emotions. Appraisal refers to the process of judging how important an event is to a person. Emotions are induced when one person encounters an event and judges how important the event is to him or her, but if aesthetic enough, need not be important. In multimedia learning situations, emotions are induced when users interact with a multimedia design. As discussed previously, Mayer's cognitive theory of multimedia learning explains how multimedia learning occurs through both verbal and audio channels, in working memory and in long-term memory. However, the amount of information processed by each channel at one time is limited. The capacity of working memory is also limited. Do positive emotions affect the capacity of the two information-processing channels and the capacity of the working memory? Further research is needed to answer the question.

The model suggests a set of prescriptive propositions that are obtained from deductively and inductively established relationships between related concepts, theories, and empirical research in the field of emotions, aesthetics, learning, and multimedia design. Prescriptive propositions point out what should be done by the multimedia designers during design or what kind of strategies should be applied in order to elicit the desired emotional outcomes from the users.

Suggestions for Attractive Multimedia Design

There clearly exist individual and cultural differences regarding perceived attractiveness. However, common psychological mechanisms shared by all human beings underlie aesthetics that can be incorporated into multimedia interfaces. A review of research on aesthetics and graphic design indicates the design elements related to multimedia aesthetic, including color, graphics, text, audio, and video.

1. **Color:** Colors in graphics serve informational, compositional, and expressive functions, which black-and-white designs do not possess (Zetll, 2005). Color energy refers to users' aesthetic responses to a color. The energy of a color is determined by "(1) the hue, saturation, and brightness of a color; (2) the size of the colored area; and (3) the relative contrast between foreground and background colors" (Zetll, p. 67). Saturation influences color energy most. High saturation means high energy, and vice versa. High-energy warm colors generally induce a happier mood on users than do low-energy cool colors. High brightness colors have higher energy than low brightness colors. The color combination of small areas of high-energy colors against large background areas of low-energy colors is perceived as pleasant. The most pleasant background hues are blue, blue-green, green, red-purple, purple, and purple-blue (Valdez & Mehrebian, 1994).
2. **Graphic:** Gestalt theory claims that different elements, when combined as a whole, reveal more information than elements viewed in isolation (Wertheimer, 1923). The practical implication of the Gestalt theory for graphic design is emphasis on relationships between different well-designed elements. The purpose of the design is to reflect abstract scientific concepts and relationships thereby helping users to create accurate mental models of them. The ratio between an element and its context should reflect the actual ratio so that the graphics portray relationships precisely. For example, the Earth and Sun's relative sizes and separating distances should be accurately reflected in illustrated

objects and their parts (Holliday, 2001). The details revealed by a graphic affects users' interpretations of the graphic. Too much information distracts users from essential information because their eyes might not know where to go (Wittich & Schuller, 1967). In a pace-controlled learning environment, graphics with relatively small amounts of information (e.g., simple line drawings) tend to be more effective (Dwyer, 1972). Most computer displays follow a 3:4 aspect ratio so the screen area of a design should also follow an approximate 3:4 ratio. According to Zettl (2005), a 3:4 ratio ensures that the difference between height and width is not obvious and users will not emphasize one dimension over the other. Graphic conventions familiar to target audiences should be used.

3. **Text:** Borchardt (1999) creates a vision scheme for the design of texts. The scheme includes size, locale, proportionality, color, and contrast of texts. He points out that fonts should be legible and in proportion to the graphics. Zettl (2005) emphasizes the importance of continuity, which means that the text should maintain its colors and size throughout the instruction. Contrast between the colors of texts and their background should remain the same as the contrast between the graphics and background.
4. **Animation:** According to Holliday (2001), it is necessary to "highlight, reintegrate, reinforce, and rehearse" some parts of the graphic design to effectively explain a scientific phenomenon (p. 8). For example, slow motion is used to highlight certain parts of an animation. To achieve slow motion, frame density is increased, that is, the motion is divided into more frames during the actual filming). In animation design, slow motion animation also runs through more frames per second than normal.
5. **Audio:** According to Borchardt (1999), factors that influence the quality of sounds include volume, pitch, timbre, attack and decay, rhythm, duration, velocity, acceleration, iteration, periodicity, familiarity, and predictability. Borchardt integrates these factors and creates an audio scheme to evaluate the quality of audio. He puts each of the factors on a spectrum. The left-hand side of the spectrum indicates low and the right-hand side for high. In general, when these factors are in the middle of a spectrum, the audio is most pleasant. Zettl (2005) proposes that sound aesthetics are determined by perspective, continuity, and picture-sound combination. Perspective means to match louder sounds with close-up pictures and far-away sounds with long shots. Sound continuity means that the sound retains its volume and quality. Another factor is picture-sound combination. I suggest using a homophonic video-audio structure, because multimedia learning is more effective when corresponding audio and video information is presented simultaneously (Mayer, 2001).

FUTURE TRENDS

Although interface design has been shown to impact multimedia learning by moderating users' emotions, there are many unanswered questions about how to define attractive interfaces and how to design attractive interface that account for individual differences in aesthetic perception. Although common aesthetic criteria exist, individual differences are still important. Philosophers have researched aesthetics for more than two centuries, so extensive literature review on aesthetics should be conducted to enlighten the research of attractive interface design. In industrial design, designers also have been trying to create attrac-

tive design for a long time and have proposed practical suggestions to make designs more attractive. Future research is needed to combine the results from aesthetics and industrial design and, in particular, to promote attractive design in learning environments.

Research on emotions, including the benefits of positive emotions, has also been conducted for more than one century. However, the mechanism underlying how positive emotions stimulate cognition is not yet clear. This explains the lack of consensus among psychologists regarding the relationship between positive emotions and cognition. Fredrickson's (1998) theory is theoretically sound, but not sufficiently supported by experiments, so her theory of positive emotions requires further exploration. More experimental studies specifically addressing the affect of positive emotions on learning particularly in the fast global Internet world are needed.

Educators have been training students to help them understand their emotions and to control their emotions, and researchers have evaluated their success. However, educators have generally neglected to design learning materials and learning environments that promote positive emotions specifically to enhance learning. In multimedia learning environments specifically, none of these issues have been adequately addressed, especially with respect to immersive, innovative technologies. Future research should also consider other aspects of learning materials and environments that impact students' emotions.

Research on how people learn indicates that the following elements impact learning, that is, teachers, instructional strategies, learners, learning materials, learning environments, and learning strategies. As discussed in this chapter, interface design is a part of the learning environment that impacts users' emotions, and emotions are believed to greatly impact learning. So what aspects in the previously mentioned elements will most significantly enhance learning? This more general and essential question should be addressed in the future research.

CONCLUSION

In his article "*Multimedia Learning: Are We Asking the Right Questions*?" Mayer (1997) noted, "At this time, the technology for multimedia education is developing at a faster pace than a corresponding science of how people learn in multimedia environments" (p. 4). Now, 10 years later this is even more true! It is essential for researchers to understand how people learn in multimedia environments. From the instructional designers' perspective, it is also important to understand how different designs impact users' emotions, and how the induced positive emotions promote learning. Multimedia development should be informed by theories tested by experimental research so that multimedia designs that predictably induce positive emotions and thereby promote multimedia learning can be developed.

KEY TERMS

Aesthetics: Both the study of beauty and the properties of a system that appeal to the senses, as opposed to the content, structures, and utility of the system itself (Budd, 1995).

Emotions: Refer to mental states (Cornelius, 1996). The cognitive perspective of emotions focuses on the role that thought plays in the process of emotions (Arnold, 1960).

Multimedia Design: The presentation of materials both in words and pictures (Mayer, 2001).

Multimedia Learning: Refers to learning from multimedia design, that is, words and pictures (Mayer, 2001).

Interface Design: Refers to how the design presents information to users so that users can process information as required to complete a task (Raskin, 2000).

Positive Emotions: A category of emotions, sharing features identified by the theories on emotions. Positive emotions promote cognitive activities.

Usability: "The degree to which people (users) can perform a set of required tasks" (Brink, Gergle, & Wood, 2002).

Chapter 5.19
Incorporating and Understanding the User Perspective

Stephen R. Gulliver
Brunel University, UK

ABSTRACT

This chapter introduces a selection of studies relating to each of the multimedia senses — olfactory (smell), tactile/haptic (touch), visual (sight), and auditory (sound) — and how such studies impact user perception and ultimately user definition of multimedia quality. A model of distributed multimedia is proposed, to allow a more structured analysis of the current literature concerning video and audio information. This model segregates studies implementing quality variation and/or assessment into three discrete information abstractions (the network, media, and content levels) and from two perspectives (the technical and user perspectives). It is the objective of the author that, by placing current research in context of a quality structure, the need for fuller incorporation of the user perspective in multimedia quality assessment will be highlighted.

INTRODUCTION

Multimedia quality is a multi-faceted concept that means different things to different people (Watson & Sasse, 1997). Multimedia quality definition involves the integration of quality parameters at different levels of abstraction and from different perspectives. Indeed, the perception of multimedia quality may be affected by numerous factors, for example, delay or loss of a frame, audio clarity, lip synchronisation during speech, video content, display size, resolution, brightness, contrast, sharpness, colourfulness, as well as naturalness of video and audio content, just to name a few (Ahumada & Null, 1993; Apteker, Fisher, Kisimov, & Neishlos, 1995; Klein, 1993; Martens & Kayargadde, 1996; Roufs, 1992). Moreover, as multimedia applications reflect the symbiotic *infotainment* duality of multimedia, that is, the ability to transfer information to the

user while also providing the user with a level of subjective satisfaction, incorporating the user perspective in a multimedia quality definition is further complicated since a comprehensive quality definition should reflect both how a multimedia presentation is understood by the user, yet also examine the user's level of satisfaction. Interestingly, all previous studies fail to either measure the infotainment duality of distributed multimedia quality or comprehensively incorporate and understanding the user-perspective.

Inclusion of the user-perspective is of paramount importance to the continued uptake and proliferation of multimedia applications since users will not use and pay for applications if they are perceived to be of low quality. In this chapter, the author aims to introduce the reader to work relating to each of the multimedia senses and how such studies impact user perception and definition of multimedia quality. The author proposes a model in which quality is looked at from three distinct levels: the *network-*, the *media-* and the *content-levels*; and from two views: the *technical-* and the *user-perspective.* This model is used to help structure, specifically current sight and sound literature, in order to help outline the diverse approaches used when varying and assessing multimedia quality, and ultimately to emphasize the need for fuller incorporation of the user perspective in multimedia quality assessment.

PERCEPTUAL STUDIES AND IMPLICATIONS

In this section we aim to introduce the reader to the studies relating to the four multimedia senses that lie at the core of the human perceptual/sensory experience.

Olfactory

Research in the field of olfaction is limited, as there is no consistent method of testing user capability of smell. The first smell-based multimedia environment (sensorama) was developed by Heilig (1962, 1992), which simulated a motorcycle ride through New York and included colour 3D visual stimuli, stereo sound, aroma, and tactile impacts (wind from fans, and a seat that vibrated).

A major area of olfactory research has been to explore whether scent can be recorded and therefore replayed to aid olfactory perceptual displays (Davide, Holmberg, & Lundstrom, 2001; Ryans, 2001). Cater (1992, 1994) successfully developed a wearable olfactory display system for a fire fighters training simulation with a Virtual Reality (VR) oriented olfactory interface controlled according to the users location and posture. In addition, researchers have used olfaction to investigate the effects of smell on a participant's sense of presence in a virtual environment and on their memory of landmarks. Dinh, Walker, Bong, Kobayashi, and Hodges (2001) showed that the addition of tactile, olfactory, and/or auditory cues within a virtual environment increased the user's sense of presence and memory of the environment.

Tactile/Haptics

Current research in the field of haptics focuses mainly on either sensory substitution for the disabled (tactile pin arrays to convey visual information, vibro-tactile displays for auditory information) or use of tactile displays for teleoperation (the remote control of robot manipulators) and virtual environments. Skin sensation is essential, especially when participating in any spatial manipulation and exploration tasks (Howe, Peine, Kontarinis, & Son, 1995). Accordingly, a number of *tactile display* devices have been developed that simulate sensations of contact. While "tactile display" describes any apparatus that provides haptic feedback, tactile displays can be subdivided into the follow groups:

- **Vibration** sensations can be used to relay information about phenomena, such as

surface texture, slip, impact, and puncture (Howe et al. 1995). Vibration is experienced as a general, non-localised experience, and can therefore be simulated by a single vibration point for each finger or region of skin, with an oscillating frequency range between 3 and 300 Hz (Kontarinis & Howe, 1995; Minsky & Lederman, 1996).

- **Small-scale shape or pressure** distribution information is more difficult to convey than that of vibration. The most commonly-used approach is to implement an array of closely aligned pins that can be individually raised and lowered against the finger tip to approximate the desired shape. To match human finger movement, an adjustment frequency of 0 to 36 Hz is required, and to match human perceptual resolution, pin spacing should be less than a few millimetres (Cohn, Lam, & Fearing, 1992; Hasser & Weisenberger, 1993; Howe et al., 1995).
- **Thermal displays** are a relatively new addition to the field of haptic research. Human fingertips are commonly warmer than the "room temperature". Therefore, thermal perception of objects in the environment is based on a combination of thermal conductivity, thermal capacity, and temperature. Using this information allows humans to infer the material composition of surfaces as well as temperature difference. A few thermal display devices have been developed in recent years that are based on Peltier thermoelectric coolers, solid-state devices that act as a heat pump, depending on direction of current (Caldwell & Gosney, 1993; Ino, Shimizu, Odagawa, Sato, Takahashi, Izumi, & Ifukube, 2003).

Many other tactile display modalities have been demonstrated, including *electrorheological devices* (a liquid that changes viscosity electroactively) (Monkman, 1992), *electrocutaneous stimulators* (that covert visual information into a pattern of vibrations or electrical charges on the skin), *ultrasonic friction displays*, and *rotating disks* for creating slip sensations (Murphy, Webster, & Okamura, 2004).

Sight and Sound

Although the quality of video and audio are commonly measured separately, considerable findings shows that audio and video information is symbiotic in nature, that one medium can have an impact on the user's perception of the other (Rimmel,, Hollier, & Voelcker, 1998; Watson & Sasse, 1996). Moreover, the majority of user multimedia experience is based on both visual and auditory information. As a symbiotic relationship has been demonstrated between the perception of audio and video media, in this chapter we consider multimedia studies concerning the variation and perception of sight and sound together.

Considerable work has been done looking at different aspects of perceived audio and video quality at many different levels. Unfortunately, as a result of multiple influences on user perception of distributed multimedia quality, providing a succinct, yet extensive review of such work is extremely complex.

To this end, we propose an extended version of a model initially suggested by Wikstrand (2003), in which quality is segregated into three discrete levels: the *network-level*, the *media-level* and the *content-level*. Wikstrand showed that all factors influencing distributed multimedia quality (specifically audio and/or video) can be categorised by assessing and categorising the specific information abstraction. The network-level concerns the transfer of data and all quality issues related to the flow of data around the network. The media-level concerns quality issues relating to the transference methods used to convert network data to perceptible media information, that is, the video and audio media. The content-level concerns quality factors that influence how media information is perceived and understood by the end user.

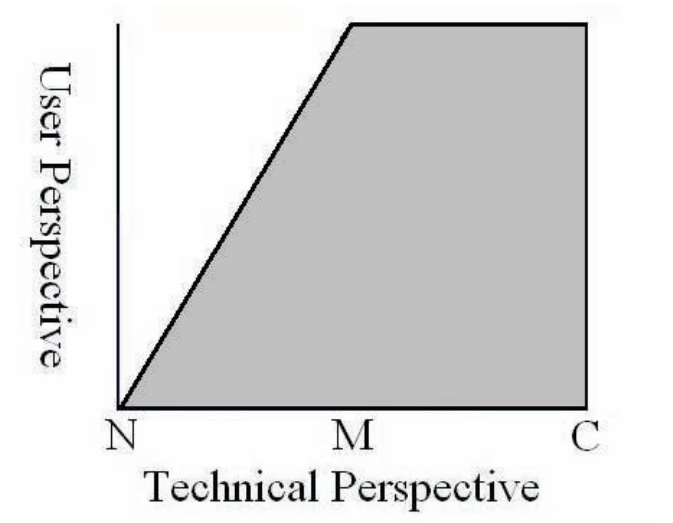
In our work, and in addition to the model proposed by Wikstrand, we incorporated two distinct quality perspectives, which reflect the infotainment duality of multimedia: the user-perspective and the technical-perspective.

- **User-Perspective:** The user-perspective concerns quality issues that rely on user feedback or interaction. This can be varied and measured at the media- and content-levels. The network-level does not facilitate the user-perspective since user perception cannot be measured at this low level abstraction.
- **Technical-Perspective:** The technical-perspective concerns quality issues that relate to the technological factors involved in distributed multimedia. Technical parameters can be varied and measured at all quality abstractions.

At each quality abstraction defined in our model, quality parameters can be varied, for example, jitter at the network-level, frame rate at the media-level, and the display-type at the content-level. Similarly, at each level of the model, quality can be measured, for example, percentage of loss at the network-level, user mean opinion score (MOS) at the media-level, and task performance at the content-level. By determining the abstraction and perspective at which experimental variables are both varied and measured, it is possible to place any multimedia experiment in context of our model.

Using the above model we aid to produce a succinct yet extensive summary of video/ audio multimedia research. The subsequent sections describe this video/audio literature in context of the identified quality definition model (see Figure 1). Each section concerns a quality abstraction level (network, media, or content-level) and includes work relating to studies that adapt and measure quality factors at the defined perspectives (both technical- or media-perspective). Each subsection includes a summary of all relevant studies. A detailed description of new studies is given at the end of the relevant section.

Figure 1. Quality model incorporates network (N), media (M), and content-level (C) abstractions and technical- and user-perspectives dimensions



The Network-Level

Network-Level Quality (Technical-Perspective)

- Claypool and Tanner (1999) manipulated jitter and packet loss to test the impact on user quality opinion scores.
- Ghinea and Thomas (2000) manipulated bit error, segment loss, segment order, delay, and jitter in order to test the impact of different media transport protocols on user perception understanding and satisfaction of a multimedia presentation.
- Procter, Hartswood, McKinlay, and Gallacher (1999) manipulated the network load to provoke degradations in media quality.
- Loss occurs due to network congestion and can therefore be used as an indication of end-to-end network performance or "quality" (Ghinea, Thomas, & Fish, 2000; Koodli & Krishna, 1998).
- A delay is always incurred when sending distributed video packets; however, the delay of consecutive packets is rarely constant. The variation in the period of delay is called the jitter. Wang et al. (2001) used jitter as an objective measure of video quality.
- The end-to-end bandwidth is defined as the network resource that facilitates the provision of these media-level technical parameters. Accordingly, the available end-to-end bandwidth is important since it determines the network resource available to applications at the media-level. Wang, Claypool, and Zuo (2001) measured bandwidth impact for their study of real-world media performance.

Claypool and Tanner (1999): Claypool and Tanner measured and compared the impact of jitter and packet loss on perceptual quality of distributed multimedia video.

Results showed that:

- Jitter can degrade video quality nearly as much as packet loss. Moreover, the presence of even low amounts of jitter or packet loss results in a severe degradation in perceptual quality. Interestingly, higher amounts of jitter and packet loss do not degrade perceptual quality proportionally.
- The perceived quality of low temporal aspect video, that is, video with a small difference between frames, is not impacted as much in the presence of jitter as video with a high temporal aspect.
- There is a strong correlation between the average number of quality degradation events (points on the screen where quality is affected) and the average user quality rating recorded. This suggests that the number of degradation events is a good indicator of whether a user will like a video presentation affected by jitter and packet loss.

Ghinea and Thomas (2000): Ghinea and Thomas tested the impact on user Quality of Perception (QoP) of an adaptable protocol stacks geared towards human requirements (RAP - Reading Adaptable Protocol), in comparison to different media transport protocols (TCP/IP, UDP/IP). RAP incorporates a mapping between QoS parameters (bit error rate, segment loss, segment order, delay and jitter) and Quality of Perception (the user understanding and satisfaction of a video presentation). Video material used included 12- windowed (352*288 pixel) MPEG-1 video clips, each between 26 and 45 seconds long, with a consistent objective sound quality, colour depth (8-bit) and frame rate (15 frames per second). The clips were chosen to cover a broad spectrum of subject matters, while also considering the dynamic, audio, video, and textual content of the video clip.

Results showed that:

- RAP enhanced user understanding, especially if video clips are highly dynamic. TCP/IP can be used for relatively static clips. UDP/IP performs badly, in context of information assimilation.
- Use of RAP successfully improves user satisfaction (10/12 videos). TCP/IP received the lowest associated satisfaction ratings.
- RAP, which incorporates the QoS to QoP mapping (Ghinea et al., 2000), is the only protocol stack used, which was not significantly different to those identified when video were shown on a standalone system. Accordingly, RAP effectively facilitates the provision of user QoP.

Koodli and Krishna (1998): Koodli and Krishna describe a metric called noticeable loss. Noticeable loss captures inter-packet loss patterns and can be used in source server and network buffers to pre-emptively discard packets based on the "distance" to the previous lost packet of the same media stream. Koodli and Krishna found that incorporation of noticeable loss greatly improves the overall QoS, especially in the case of variable bit rate video streams.

Procter et al. (1999): Procter et al. focus on the influence of different media content and network Quality of Service (QoS) variation on a subject's memory of, and comprehension of, the video material. In addition, Procter et al. focus on the impact of degraded visual information on assimilation of non-verbal information.

A simulation network was used to facilitate QoS variation. Two 4-Mbs token rings were connected by a router, so that packets had to pass through the router before being received by the client. Two background traffic generators were used to generate two network conditions: i) no load (with no traffic), and ii) load (with simulated traffic). During the load condition, packet loss was "bursty" in character, varying between zero and one hundred percent, yet had an overall average between 30% and 40%. Audio quality was subsequently dependent on network conditions. Video material used consisted of two diametrically- opposed presentations: a bank's annual report and a dramatized scene of sexual harassment. Two experiments were used:

- The first experiment was designed to investigate the effects of network QoS on a subject's assessment of quality. Two questionnaires were used: The first concerned the subjective evaluation of quality (with scores 1-5 representing very poor and very good respectively) as well as factors that had impaired quality (caption quality, audio quality, video quality, audio/video synchronisation, and gap in transmission); the second questionnaire measured a participants' comprehension of the material based upon their recall of its factual content. Results showed that subjects rated the quality higher in the non-load than in the load condition, with overall impression, ease of understanding, and technical quality being the significantly better quality with no network load. Two factors were found to significantly impair quality in the no-load network condition: video quality and audio/video synchronisation. When a network load was added, audio quality, video quality, audio/video synchronisation, as well as transmission gaps were found to significantly impair user perception of multimedia quality. No difference was measured in the level of factual information assimilated by users.
- The second experiment investigated the impact of visual degradation of the visual channel on the uptake of non-verbal signals. Again, two network load conditions were used: i) no load, and ii) load, to simulate network traffic. The same test approach was used; however the second questionnaire considered: a) factual questions, b) content questions relating to what they thought was happening in a dramatised section of the

video, that is, the participants' ability to judge the emotional state of people, and c) questions asking the user to specify his/her confidence with his/her answers. Results showed that subjects rated quality higher in the no-load condition, with overall impression, content, ease of understanding, and technical quality rating being significantly higher under no-load conditions. In the no-load condition, audio, video quality, and audio-video synchronisation were considered to have an effect on user perception of multimedia quality. In the load network condition, caption quality, audio quality, video quality, audio/video synchronisation, and gap in transmission were all shown to have an impairing impact on user perception of multimedia quality. No significant difference was measured between the level of factual information assimilated by users when using load and non-load conditions. In conclusion, Procter et al. (1999) observed that degradation of QoS has a greater influence on a subject's uptake of emotive/affective content than on their uptake of factual content.

Wang, Claypool, and Zuo (2001): Wang et al. presented a wide-scale empirical study of RealVideo traffic from several Internet servers to many geographically-diverse users. They found that when played over a best effort network, RealVideo has a relatively reasonable level of quality, achieving an average of 10 video frames per second and very smooth playback. Interestingly, very few videos achieve full-motion frame-rates. Wang et al. showed that: With low-bandwidth Internet connection, video performance is most influenced by the user's limited bandwidth connection speed; with high-bandwidth Internet connection, the performance reduction is due to server bottlenecks. Wang et al. (2001) used level of jitter and video frame rates as objective measures of video quality.

The Media-Level

Media-Level Quality (Technical-Perspective)

- Apteker et al. (1995), Ghinea and Thomas (1998), Kawalek (1995), Kies, Williges, and Rosson (1997), Masry, Hemami, Osberger, and Rohaly (2001), Wilson and Sasse (2000a, 2000b), and Wijesekera, Srivastava, Nerode, and Foresti (1999) manipulated video or audio frame rate.
- Ardito, Barbero, Stroppiana, and Visca (1994) developed a metric, which aimed to produce a linear mathematical model between technical and user subjective assessment.
- Gulliver and Ghinea (2003) manipulated use of captions.
- Kies et al. (1997) manipulated image resolution.
- Quaglia and De Martin (2002) used *Peak Signal-to-Noise Ratio* (PSNR) as an objective measure of quality.
- Steinmetz (1996) and Wijesekera et al. (1999) manipulated video skew between audio and video, that is, the synchronisation between two media. In addition, Steinmetz (1996) manipulated the synchronisation of video and pointer skews.
- Teo and Heeger (1994) developed a normalised model of human vision. Extensions to the Teo and Heegar model included: the *Colour Masked Signal to Noise Ratio* metric (CMPSNR) - Van den Branden Lambrecht and Farell (1996), used for measuring the quality of still colour pictures, and the *Normalised Video Fidelity Metric* (NVFM) - Lindh and van den Branden Lambrecht (1996), for use with multimedia video. Extensions of the CMPSNR metric include: the *Moving Picture Activity Metric* (MPAM) - Verscheure and Hubaux (1996), the *Perceptual Visibility Predictor* metric

(PVP) - Verscheure and van den Branden Lambrecht (1997), and the *Moving Pictures Quality Metric* (MPQM) - van den Branden Lambrecht and Verscheure (1996).

- Wang, Claypool, and Zuo (2001) used frame rate as an objective measure of quality. Although the impact of frame rate is adapted by Apteker et al. (1995); Ghinea and Thomas (1998); Kawalek (1995); Kies et al. (1997); Masry et al .(2001); Wijesekera et al (1999), Wang et al. (2001) is, to the best of our knowledge, the only study that used output frame rate as the quality criterion.
- Wikstrand and Eriksson (2002) used various animation techniques to model football matches for use on mobile devices.

Apteker et al. (1995): Apteker et al. defined a *Video Classification Scheme* (VCS) to classify video clips (see Table 1), based on three dimensions, considered inherent in video messages: the temporal (T) nature of the data, the importance of the auditory (A) components and the importance of visual (V) components.

"High temporal data" concerns video with rapid scene changes, such as general sport highlights, "Low temporal data" concerns video that is largely static in nature, such as a talk show. A video from each of the eight categories was shown to users in a windowed multitasking environment. Each multimedia video clip was presented in a randomised order at three different frame rates (15, 10, and 5 frames per second). The users then rated the quality of the multimedia videos on a seven-point graded scale. Apteker et al. showed that:

Table 1. Video classification examples - adapted from Apteker et al (1995)

Category Number	Video Information	*Definition*
1	Logo/ Test Pattern	Tlo Alo Vlo
2	Snooker	Tlo Alo Vhi
3	Talk Show	Tlo Ahi Vlo
4	Stand-up Comedy	Tlo Ahi Vhi
5	Station Break	Thi Alo Vlo
6	Sporting Highlights	Thi Alo Vhi
7	Advertisements	Thi Ahi Vlo
8	Music Clip	Thi Ahi Vhi

- Video clips with a lower video dependence (Vlo) were considered as more watchable than those with a high video dependence (Vhi).
- Video clips with a high level of temporal data (Thi) were rated as being more watchable than those with a low level of temporal data (Tlo).
- Frame-rate reduction itself leads to progressively lower ratings in terms of "watchability".
- There exists a threshold, beyond which no improvement to multimedia quality can be perceived, despite an increase in available bandwidth, which is supported by Fukuda, Wakamiya, Murata, and Miyahara, 1997; Ghinea, 2000; Steinmetz, 1996; van den Branden Lambrecht, 1996).

Apteker et al. expressed human receptivity as a percentage measure, with 100% indicating complete user satisfaction with the multimedia data, and showed that the dependency between human receptivity and the required bandwidth of multimedia clips is non-linear (Apteker et al). In the context of bandwidth-constrained environments, results suggest that a limited reduction in human receptivity facilitates a relatively large reduction in bandwidth requirement (the *asymptotic property* of the VCS curves) (Ghinea, 2000).

Ardito et al. (1994): The RAI Italian Television metric attempts to form a linear objective model from data representing subjective assessments concerning the quality of compressed images (Ardito et al., 1994; Ghinea, 2000). During subjective assessment, the participants were

presented with a sequence of pairs of video clips, one representing the original image and the other showing the degraded (compressed) equivalent. The user is not told which of the two is the original, yet is asked to categorise the quality of the two images using a five- point Likert double-stimulus impairment scale classification similar to the CCIR Rec. 500-3 scale (CCIR, 1974), with scores of one and five representing the "very annoying" and, respectively, "imperceptible" difference between the original and degraded images. All results are then normalised with respect to the original.

The RAI Italian Television metric initially calculates the SNR for all frames of the original and degraded video clips. To enable processing over time (the temporal variable) the SNR values are calculated across all frames, as well as in subsets of specified length *l*. Minimum and maximum values of the SNR are then determined for all groups with *l* frames, thus highlighting noisy sections of video. RAI Italian Television metric considers human visual sensitivity, by making use of a Sobel operator. A Sobel operator uses the luminance signal of surrounding pixels, in a 3x3 matrix, to calculate the gradient in a given direction. Applied both vertically and horizontally, Sobel operators can identify whether or not a specific pixel is part of an edge. The 3x3 matrix returns a level of luminance variation greater or smaller, respectively, than a defined threshold. An "edge image" for a particular frame can be obtained by assigning a logical value of 1 or 0 to each pixel, depending on its value relative to the threshold. An edge image is defined for each frame, facilitating the calculation of SNR for three different scenarios: across the whole frame, only for areas of a frame belonging to edges, and, finally, across the whole frame but only for those areas not belonging to edges. Results show that, the RAI Italian Television linear model can successfully capture 90% of the given subjective information. However, large errors occur if the subjective data is applied across multiple video clips (Ardito et al., 1993), implying high content dependency.

Ghinea and Thomas (1998): To measure the impact of video Quality of Service (QoS) variation on user perception and understanding of multimedia video clips, Ghinea and Thomas presented users with a series of 12 windowed (352x288 pixel) MPEG-1 video clips, each between 26 and 45 seconds long, with a consistent objective sound quality. The clips were chosen to cover a broad spectrum of subject matter, while also considering the dynamic, audio, video, and textual content of the video clip. They varied the frame per second (fps) QoS parameters, while maintaining a constant colour depth, window size, and audio stream quality. Frame rates of 25 fps, 15 fps and 5 fps were used and were varied across the experiment, yet for a specific user they remained constant throughout. Ten users were tested for each frame rate. Users were kept unaware of the frame rate being displayed. To allow dynamic (D), audio (A), video (V) and textual (T) considerations to be taken into account, in both questionnaire design and data analysis, characteristic weightings were used on a scale of 0-2, assigning importance of the inherent characteristics of each video clip.

Table 2. Video characteristics as defined by Ghinea and Thomas (1998)

Video Category	Dynamic (D)	Audio (A)	Video (V)	Text (T)
1 – Commercial	1	2	2	1
2 – Band	1	2	1	0
3 – Chorus	0	2	1	0
4 – Animation	1	1	2	0
5 – Weather	0	2	2	2
6 – Documentary	1	2	2	0
7 – Pop Music	1	2	2	2
8 – News	0	2	2	1
9 – Cooking	0	2	2	0
10 – Rugby	2	1	2	1
11 – Snooker	0	1	1	2
12 – Action	2	1	2	0

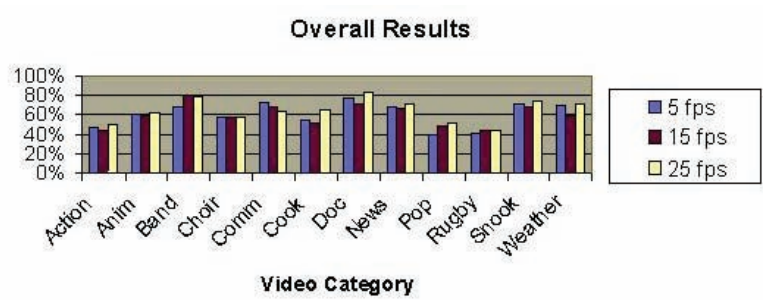
Table 2 contains the characteristic weightings, as defined by Ghinea and Thomas (1998). The clips were chosen to present the majority of individuals with no peak in personal interest, which could skew results. Clips were also chosen to limit the number of individuals watching the clip with previous knowledge and experience.

After the user had been shown a video clip, the video window was closed, and questions were asked about the video that they had just seen. The number of questions was dependent on the video clip being shown and varied between 10 and 12. Once a user had answered all questions relating to the video clip, and all responses had been noted, users were asked to rate the quality of the clip using a six-point Likert scale, with scores one and six representing the worst and, respectively, the best possible perceived level of quality. Users were instructed not to let personal bias towards the subject matter influence their quality rating of the clip. Instead they were asked to judge a clip's quality by the degree to which they, the users, felt satisfied with the service of quality. The questions, used by Ghinea and Thomas, were designed to encompass all aspects of the information being presented in the clips: *D, A, V, T.* A number of questions were used to analyse a user's ability to absorb multiple media at one point in time, as correct answers could only be given if a user had assimilated information from multiple media. Lastly, a number of the questions were used that couldn't be answered by observation of the video alone, but by the users making inference and deductions from the information that had just been presented.

The main conclusions of this work include the following:

- A significant loss of frames (that is, a reduction in the frame rate) does not proportionally reduce the user's understanding and perception of the presentation (see Figure 2). In fact, in some instances the participant seemed to assimilate more information, thereby resulting in more correct answers to questions. Ghinea and Thomas proposed that this was because the user has more time to view a specific frame before the frame changes (at 25 fps, a frame is visible for only 0.04 sec, whereas at 5 fps a frame is visible for 0.2 sec), hence absorbing more information.
- Users have difficulty in absorbing audio, visual, and textual information concurrently. Users tend to focus on one of these media at any one moment, although they may switch between the different media. This implies that critical and important messages in a multimedia presentation should be delivered in only one type of medium.
- When the cause of the annoyance is visible (such as lip synchronisation), users will dis-

Figure 2. Effect of varied QoS on user quality of perception (1998)



regard it and focus on the audio information if considered contextually important.

- Highly dynamic scenes, although expensive in resources, have a negative impact on user understanding and information assimilation. Questions in this category obtained the least number of correct answers. However, the entertainment values of such presentations seem to be consistent, irrespective of the frame rate at which they are shown. The link between entertainment and content understanding is therefore not direct.

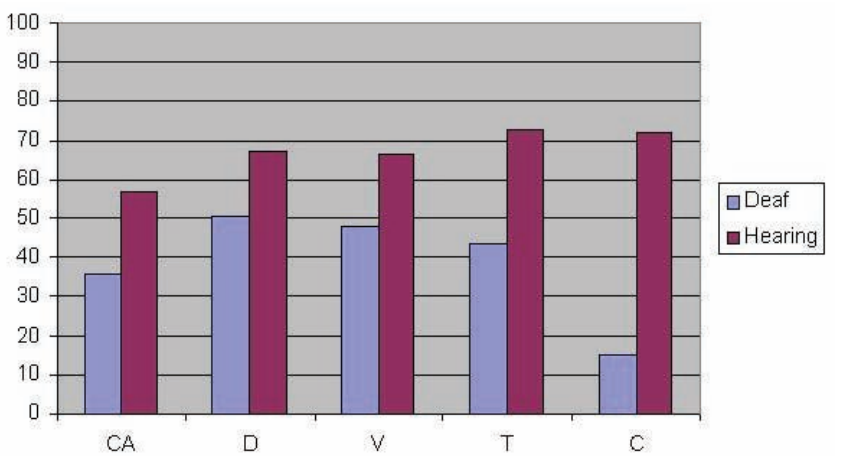
Ghinea and Thomas's method of measuring user perception of multimedia quality, later termed Quality of Perception (QoP), incorporates both a user's capability to understand the informational content of a multimedia video presentation, as well as his/her satisfaction with the quality of the visualised multimedia. QoP has been developed at all quality abstractions of our model (network-, media- and content-level) in cooperation with a number of authors: Fish (Ghinea et al. 2000), Gulliver (Gulliver and Ghinea, 2003; 2004), Magoulas (Ghinea and Magoulas, 2001) and Thomas (Ghinea and Thomas, 1998; 2000; 2001) concerning issues including the development of network protocol stacks, multimedia media assessment, attention tracking, as well user accessibility.

Gulliver and Ghinea (2003): Gulliver and Ghinea used an adapted version of QoP to investigate the impact that hearing level has on user perception of multimedia, with and without captions. They showed users a series of 10 windowed (352x288 pixel) MPEG-1 video clips, each between 26 and 45 seconds long, with a consistent sound quality and video frame rate. Additional captions were added in a separate window, as defined by the experimental design.

Results showed that deafness significantly impacts a user's ability to assimilate information (see Figure 3). Interestingly, use of captions does not increase deaf information assimilation, yet increases quality of context-dependent information assimilated from the caption/audio.

To measure satisfaction, Gulliver and Ghinea (2003) used two 11-point scales (0-10) to measure Level of Enjoyment (QoP-LoE) and user self-predicted level of Information Assimilation (QoP-PIA). A positive correlation was identified between QoP-LoE and QoP-PIA, independent of hearing level or hearing type, showing that a

Figure 3. A detailed breakdown of deaf /hearing information assimilation (%): (CA) caption window / audio, (D) dynamic information, (V) video information,(T) textual information and (C) captions contained in the video window



user's perception concerning their ability to assimilate information is linked to his/her subjective assessment of enjoyment.

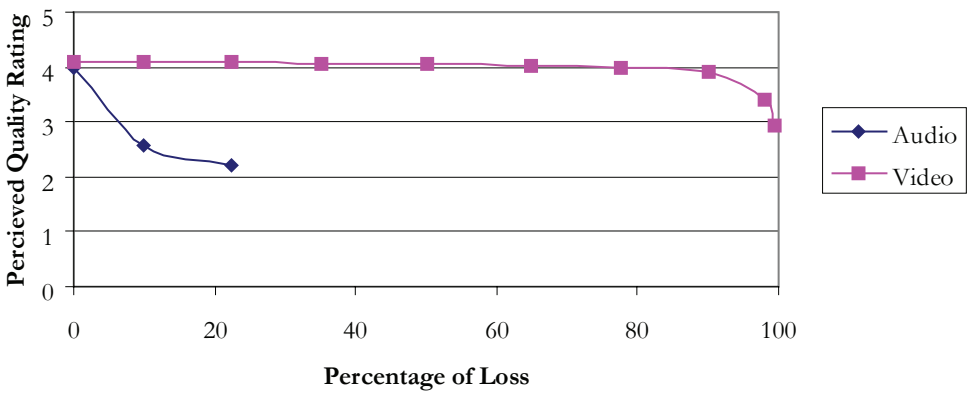
Kawalek (1995): Kawalek showed that loss of audio information has a more noticeable effect on the assimilation of informational content than video frame loss. Users are therefore less likely to notice degradation of video clips if shown low quality audio media (see Figure 4).

Kies et al. (1997): Kies et al. conducted a two-part study to investigate the technical parameters affecting a *Desktop Video Conferencing system* (DVC). Consequently, three frame rate conditions (1, 6 and 30 fps), two resolution conditions (160x120 and 320x240), and three-communication channel conditions were manipulated. Dependent measures included the results of a questionnaire and subjective satisfaction, specifically concerning the video quality. Like Ghinea and Thomas (1998) and Procter et al. (1999), results suggest that factual information assimilation does not suffer under reduced video QoS, but subjective satisfaction is significantly decreased. In addition, a field study was used to look at the suitability of DVC for distance learning. Interestingly, field studies employing similar dependent measures indicated that participants may be more critical of poor video quality in laboratory settings.

Quaglia and De Martin (2002): Quaglia and De Martin describe a technique for delivering "nearly constant" perceptual QoS when transmitting video sequences over IP Networks. On a frame-by-frame basis, allocation of premium packets (those with a higher QoS priority) depends upon on the perceptual importance of each MPEG *macroblock*, the desired level of QoS, and the instantaneous network state. Quaglia and De Martin report to have delivered nearly constant QoS; however, constant reliance on PSNR and use of frame-by-frame analysis raises issues when considering the user perception of multimedia quality.

Steinmetz (1990, 1992, 1996): Distributed multimedia synchronisation comprises both the definition and the establishment of temporal relationships amongst media types. In a multimedia context this definition can be extended such that synchronisation in multimedia systems comprises content, spatial, and temporal relations between media objects. Perceptually, synchronisation of video and textual information or video and image information can be considered as either: *overlay*, which is information that is used in addition to the video information; or *no overlay*, which is information displayed, possibly in another box, to support the current video information. Blakowski

Figure 4. Perceived effect of transmission quality on user perception - Adapted from Kawalek (1995)



and Steinmetz (1995) distinguished two different types of such media objects:

- **Time-dependent media objects:** These are media streams that are characterised by a temporal relation between consecutive component units. If the presentation duration of all components of an object is equal, then it is called a *continuous media object.*
- **Time-independent media objects:** These consist of media such as text and images. Here the semantics of their content does not depend on time-structures.

An example of synchronisation between continuous media would be the synchronisation between the audio and video streams in a multimedia video clip. Multimedia synchronisation can, however, comprise temporal relations between both time-dependent and time-independent media objects. An example of this is a slide presentation show, where the presentation of the slides has to be synchronised with the appropriate units of the audio stream. Previous work on multimedia synchronisation was done in Blakowski and Steinmetz, (1995) and Steinmetz, (1990, 1992, 1996). as well as on topics devoted to device synchronisation requirements. Steinmetz (1990, 1992, 1996) primarily manipulated media skews to measure how lip pointer and non-synchronisation impacted user perception of what is deemed "out of synch" (Steinmetz, 1996). A presentation was considered as being "in synch" when no error was identified, that is, a natural impression. A presentation was considered as being "out of synch" when it is perceived as being artificial, strange, or even annoying. Table 3 summarises the minimal synchronisation errors, proposed by Steinmetz, that were found to be perceptually acceptable between media (see Table 3).

Further experiments incorporating variation in video content, as well as the use of other languages (Spanish, Italian, French, and Swedish) showed no impact on results. Interestingly, Steinmetz did measure variation as a result of the participant group, implying that user experience of manipulating video affects a user's aptitude when noticing multimedia synchronisation errors.

Teo and Heeger (1994): Teo and Heeger present a perceptual distortion measure that predicts

Table 3. Minimal noticeable synchronisation error Steinmetz (1996)

Media		**Mode, Application**	**QoS**
Video	Animation	Correlated	±120ms
	Audio	Lip synchronisation	±80ms
	Image	Overlay	±240ms
		Non-overlay	±500ms
	Text	Overlay	±240ms
		Non-overlay	±500ms
Audio	Animation	Event correlation (e.g. dancing)	±80ms
	Audio	Tightly coupled (stereo)	±11μs
		Loosely coupled (e.g. background music)	±500ms
	Image	Tightly coupled (e.g. music with notes)	±5ms
		Loosely coupled (e.g. slide show)	±500ms
	Text	Text annotation	±240ms
	Pointer	Audio relates to showed item	(-500ms, +750ms)

image integrity based on a model of the human visual system that fits empirical measurements of: 1) the response properties of neurons in the primary visual cortex, and 2) the psychophysics of spatial pattern detection, that is a person's ability to detect a low contrast visual stimuli.

The Teo-Heeger model consists of four steps:

- **a front-end hexagonally sampled quadrature mirror filter transform** function (Simoncellia & Adelson, 1990) that provides an output similar to that of retina, and is similarly tuned to different spatial orientations and frequencies.
- **squaring** to maximise variation.
- **a divisive contrast normalisation mechanism**, to represent the response of a hypothetical neuron in the primary visual cortex.
- **a detection mechanism** (both linear and non-linear) to identify differences (errors) between the encoded image and the original image.

Participants rated images, coded using the Teo and Heeger perceptual distortion measure, as being of considerably better "quality" than images coded with no consideration to the user-perspective. Interestingly, both sets of test images contain similar RMS and PSNR values.

van den Branden Lambrecht and Verscheure (1996): van den Branden Lambrecht and Verscheure present the Moving Picture Quality Metric (MPQM) to address the problem of quality estimation of digital coded video sequences. The MPQM is based on a multi-channel model of the human spatio-temporal vision with parameters defined through interpretation of psychophysical experimental data.

A spatio-temporal filter bank simulates the visual mechanism, which perceptually decomposes video into phenomena such as contrast sensitivity and masking. Perceptual components are then combined, or pooled, to produce a quality rating, by applying a greater summation weighting for areas of higher distortion. The quality rating is then normalised (on a scale from one to five), using a normalised conversion. van den Branden Lambrecht and Verscheure showed MPQM (moving picture quality metric) to model subjective user feedback concerning coded video quality.

Lindh and van den Branden Lambrecht (1996): Lindh and van den Branden Lambrecht introduced the NVFM model (Normalisation Video Fidelity Metric), as an extension of the normalisation model used by Teo and Heeger. The NVFM output accounts for normalisation of the receptive field responses and inter-channel masking in the human visual system and is mapped onto the one to five quality scale on the basis of the vision model used in the MPQM metric.

Lindh and van den Branden Lambrecht compared NVFM with the Moving Picture Quality Metric (MPQM) (van den Branden Lambrecht & Verscheure, 1996). Interestingly, the results of NVFM model are significantly different from the output of the MPQM, as it has a fast increase in user perceived quality in the lower range of bit rate, that is, a slight increase of bandwidth can result in a very significant increase in quality. Interestingly, saturation occurs at roughly the same bit rate for both metrics (approximately 8 Mbit/sec). Lindh and van den Branden Lambrecht proposed NVFM as a better model of the cortical cell responses, compared to the MPQM metric.

van den Branden Lambrecht and Farrell (1996): van den Branden Lambrecht and Farrell introduced a computation metric, which is termed the Colour Masked Signal to Noise Ratio (CMSNR). CMSNR incorporates opponent-colour (i.e. the stimulus of P-ganglion cells), as well as other aspects of human vision involved in spatial vision including: perceptual decomposition (Gabor Filters), masking (by adding weightings to screen areas), as well as the weighted grouping of neuron outputs. van den Branden Lambrecht and Farrell subsequently validated the CMPSNR

metric, using 400 separate images, thus proving the CMPSNR metric as more able to predict user fidelity with a level of accuracy greater than the mean square error.

Wijesekera et al. (1999): A number of mathematical measures of QoS (Quality of Service) models have been proposed (Towsley, 1993; Wijesekera & Stivastava, 1996). Wijesekera & Stivastava (1996) investigated the perceptual tolerance to discontinuity caused by media losses and repetition. Moreover, Wijesekera et al. considered the perceptual impact that varying degrees of synchronisation error have across different streams. Wijesekera et al. followed the methodology of Steinmetz (1996), that is, the manipulation of media skews, to measure stream continuity and synchronisation in the presence of media losses (Wijesekera & Stivastava, 1996) and consequently, quantified human tolerance of transient continuity and synchronisation losses with respect to audio and video media. Wijesekera et al. (1999) found that:

- Viewer discontent with aggregate losses (i.e. the net loss, over a defined duration) gradually increases with the amount of loss, as long as losses are evenly distributed. For other types of loss and synchronisation error, there is a sharp initial rise in user discontent (to a certain value of the defect), after which the level of discontent plateaus.
- When video is shown at 30fps, an average aggregate loss below 17% is imperceptible, between 17% and 23% it is considered tolerated, and above 23% it is considered unacceptable, assuming losses are evenly distributed.
- Losing two or more consecutive video frames is noticed by most users, when video is shown at 30fps. Losing greater than two consecutive video frames does not proportionally impact user perception of video, as a quality rating plateau is reached. Similarly, loss of three or more consecutive audio frames was noticed by most users. Additional consecutive loss of audio frames does not proportionally impact user perception of audio, as a quality rating plateau is reached.
- Humans are not sensitive to video rate variations. Alternatively, humans have a high degree of sensitivity to audio, thus supporting the findings of Kawalek (1995). Wijesekera et al. (1999) suggest that even a 20% rate variation in a newscast-type video does not result in significant user dissatisfaction, whereas a 5% rate variation in audio is noticed by most observers.
- Momentary rate variation in the audio stream, although initially considered as being amusing, was soon considered as annoying. This resulted in participants concentrating more on the audio defect than the audio content.
- An aggregated audio-video synchronisation loss of more that 20% frames was identified. Interestingly, consecutive synchronisation loss of more than three frames is identified by most users, which is consistent with Steinmetz (1996).

Wilson and Sasse (2000a, 200b): Bouch, Wilson, and Sasse (2001) proposed a three-dimensional approach to assessment of audio and video quality in networked multimedia applications: measuring task performance, user satisfaction, and user cost (in terms of physiological impact). Bouch et al. used their approach to provide an integrated framework from which to conduct valid assessment of perceived QoS (Quality of Service). Wilson and Sasse (2000b) used this three-dimensional approach and measured: Blood Volume Pulse (BVP), Heart Rate (HR) and Galvanic Skin Resistance (GSR), to measure the stress caused when inadequate media quality is presented to a participant. Twenty-four participants watched two recorded interviews conducted, using IP video tools, lasting fifteen minutes each. After every five minutes, the quality of the video was changed,

allowing quality variation over time. Audio quality was not varied. Participants therefore saw two interviews with video frame rates of 5-25-5 fps and 25-5-25 fps respectively. While viewing the videos, participants rated the audio/video quality using the QUASS tool (Bouch, Watson, & Sasse, 1998), a *Single Stimulus Continuous Quality* (SSCQE) system where the participant continuously rated quality on an unlabelled scale. Physiological data was taken throughout the experiment. Moreover, to measure whether users perceived any changes in video quality, a questionnaire was also included. Wilson and Sasse showed that the GSR, HR, and BVP data represented significant increases in stress when a video is shown at 5fps in comparison to 25fps. Only 16% of participants noticed a change in frame rate. No correlation was found between stress level and user feedback of perceived quality.

Wilson and Sasse (2000a) showed that subjective and physiological results do not always correlate with each other, which indicates that users cannot consciously evaluate the stress that degraded media quality has placed upon them.

Wikstrand and Eriksson (2002): Wikstrand and Eriksson used animation to identify how alternative rendering techniques impact user perception and acceptance, especially in bandwidth-constrained environments. An animation or model of essential video activity demands that only context-dependent data is transferred to the user and therefore reduces data transfer. Wikstrand and Eriksson performed an experiment to contrast different animations and video coding in terms of their cognitive and emotional effectiveness when viewing a football game on a mobile phone. Results showed that different rendering of the same video content affects the user's understanding and enjoyment of the football match. Participants who preferred video to animations did so because it gave them a better "football feeling", while those who preferred animations had a lower level of football knowledge and thought that animations were best for understanding the game. Wikstrand and Eriksson concluded that more advanced rendering, at the client end, may be used to optimise or blend between emotional and cognitive effectiveness.

Media-Level Quality (User-Perspective)

- Apteker et al. (1995), measured "watchability" (receptivity) as a measure of user satisfaction concerning video quality.
- Ghinea and Thomas (1998) asked respondents to rate the quality of each clip on a seven- point Likert scale.
- Procter et al. (1999) asked subjects to compare the streamed video against the non-degraded original video. Quality was measured by asking participants to consider a number of statements and, using a seven-point Likert-style scale, for example, "the video was just as good as watching a live lecture in the same room" and "the video was just as good as watching a VCR tape on a normal television".
- Steinmetz (1996) used participant annoyance of synchronisation skews as a measure of quality. In both cases only identified errors are considered as being of low quality.
- Wilson and Sasse (2000a; 2000b) used the *Single Stimulus Continuous Quality* QUASS (Bouch et al., 1998) tool to allow the user to continuously rate the audio / video quality, whilst viewing a video presentation.
- Wikstrand and Eriksson (2002) measured user preference concerning the animation rendering technique.

The media-level is concerned with how the media is coded for the transport of information over the network and/or whether the user perceives the video as being of good or bad quality. Accordingly, studies varying media quality, as a direct result of the user, are limited. The best example of quality-related user media variation concerns attentive displays, which manipulate video quality

around a user's point of gaze. Current attentive display techniques were first introduced in McConkie and Rayner (1975) and Saida and Ikeda (1979) and are used in a wide range of applications, including: reading, perception of image and video scenes, virtual reality, computer game animation, art creation and analysis, as well as visual search studies (Baudisch, DeCarlo, Duchowski, & Geisler, 2003; Parkhurst & Niebur, 2002; Wooding, 2002). The perceptual work relating to the use of attentive displays is of limited benefit to the aim of this work and will therefore not be considered in this chapter.

The Content-Level

Content-Level Quality (Technical-Perspective)

- Ghinea and Thomas (1998), Gulliver and Ghinea (2003), Masry et al. (2001), as well as Steinmetz (1996) all varied experimental material to ensure diverse media content.
- Procter et al. (1999) used diametrically opposed presentations: a bank's annual report and a dramatized scene of sexual harassment.
- Steinmetz (1996) used three different views: head, shoulder, and body, which related to the relative proportion of the newsreader shown in the video window.
- Wilson and Sasse (2000a, 2000b) measure participants Blood Volume Pulse (BVP), Heart Rate (HR) and Galvanic Skin Resistance (GSR), to measure for stress as a result of low quality video.

Content-Level Quality (User-Perspective)

- Apteker et al. (1995) measured "watchability" (receptivity) as a measure of user satisfaction concerning video content along temporal, visual, and audio dimensions. Accordingly, "watchability" covers both media- and content-levels.
- Ghinea and Thomas (1998), and Gulliver and Ghinea (2003) used questionnaire feedback to measure a user's ability to assimilate and understand multimedia information.
- Gulliver and Ghinea (2003) asked participants to predict how much information they had assimilated during IA tasks, using scores of 0 to 10 representing "none" and, respectively, "all" of the information that was perceived as being available. Gulliver and Ghinea also measured a participant's level of enjoyment, using scores of 0 to 10 representing "none" and, respectively, "absolute" enjoyment.
- Gulliver and Ghinea (2003) varied participant demographics to measure changes in multimedia perception as a result of deafness, deafness type, and use of captions.
- Procter et al. (1999) used "ease of understanding", "recall", "level of interest", and "level of comprehension" as quality measures.
- Steinmetz (1996) tested videos using a variety of languages (Spanish, Italian, French, and Swedish) in order to check lip synchronisation errors.
- Watson and Sasse (2000) varied peripheral factors, such as volume and type of microphone, to measure in a CSCW environment, the impact on user perception of audio quality.
- Wikstrand and Eriksson (2002) adapted animation rendering techniques, while maintaining important presentation content. Wikstrand and Eriksson showed that animation rendering affects user's understanding and enjoyment of a football match.

Watson and Sasse (2000): Watson and Sasse showed that volume discrepancies, poor quality microphones, and echo have a greater impact on a user's perceived quality of network audio than packet loss.

INCORPORATING THE USER-PERSPECTIVE

Studies have shown that at the:

- **Network-Level:** Technical-perspective network-level variation of bit error, segment loss, delay, and jitter has been used to simulate QoS deterioration. Technical-perspective network-level measurements of loss, delay, and jitter, as well as allocated bandwidth have all been used to measure network level quality performance.
- **Media-Level:** Technical-perspective media-level variation of video and audio frame rate, captions, animation method, inter-stream audio-video quality, image resolution, media stream skews, synchronisation and video compression codecs have been used to vary quality definition. Technical-perspective media-level measurement is generally based on linear and visual quality models, with the exception of who uses output frame rate as the quality criterion. User-perspective media-level variation requires user data feedback and is limited to attentive displays, which manipulate video quality around a user's point of gaze. User-perspective media-level measurement of quality has been used when measuring user "watchability" (receptivity), assessing user rating of video quality, comparing streamed video against the non-degraded original video, as well as for continuous quality assessment and gauging participant annoyance of synchronisation skews.
- **Content-Level:** Technical-perspective content-level variation has been used to vary the content of experimental material as well as the presentation language. Technical-perspective content-level measurement has, to date, only included stress analysis. User-perspective content-level variation has also been used to measure the impact of user demographics, as well as volume and type of microphone on overall perception of multimedia quality. User-perspective content-level measurement has measured "watchability" (receptivity), "ease of understanding", "recall", "level of interest", "level of comprehension", information assimilation, predicted level of information assimilation, and enjoyment.

Table 4. Comparison of user perceptual studies

Study	Participants	Adapted	Measured
Apteker et al. (1995)	60 students	• Frame rate (M) • Video content (C)	• Watchability (M)(C)
Gulliver and Ghinea (2003)	50 participants (30 hearing / 20 deaf)	• Framerate (M) • Captions (M) • Video content (C) • Demographics (C)	• Information assimilation (C) • Satisfaction (C) • Self perceived ability (C)
Procter et al. (1999)	24 participants	• Network load (N) • Video content (C)	• Comprehension (C) • Uptake of non-verbal information (C) • Satisfaction (M)
Wilson and Sasse (2000a; 2000b)	24 participants	• Frame rate (M)	• Galvanic skin resistance (C) • Heart rate (C) • Blood volume pulse (C) • QUASS (M)
Ghinea and Thomas (1998)	30 participants	• Frame rate (M) • Video content (C)	• Information assimilation (C) • Satisfaction (M)

A number of studies have been considered that measure the user-perspective at the content-level (Apteker et al (1995), Ghinea and Gulliver (2003), Ghinea and Thomas (1998), Procter et al. (1999), Wilson and Sasse (2000a; 2000b). These are summarized in Table 4 which:

1. Lists the primary studies that measure the user-perspective at the content-level, stating the number of participants used in each study.
2. Identifies the adapted quality parameters, and defines the quality abstraction at which each parameter was adapted (N = Network-level, M = Media-level, C = Content-level).
3. Provides a list of the measurements taken for each study and the quality level abstraction at which each measurement was taken (N = Network-level, M = Media-level, C = Content-level).

Inclusion of the user-perspective is of paramount importance to the continued uptake and proliferation of multimedia applications since users will not use and pay for applications if they are perceived to be of low quality. Interestingly, all previous studies fail to either measure the infotainment duality of distributed multimedia quality or comprehensively incorporate and understanding the user-perspective. To extensively consider distributed multimedia quality to incorporate and understand the user-perspective, it is essential that, where possible, both technical- and user-perspective parameter variation is made at all quality abstractions of our model, that is, network-level (technical-perspective), media-level (technical- and user-perspective) and content-level (technical- and user-perspective) parameter variation. Furthermore, in order to effectively measure the infotainment duality of multimedia, that is, information transfer and level of satisfaction, the user-perspective must consider both:

- the user's ability to assimilate/understand the informational content of the video {assessing the content-level user-perspective}.
- the user's satisfaction, both measuring the user's satisfaction with the objective QoS settings {assessing the media-level user-perspective}, and also user enjoyment {assessing the content-level user-perspective}.

SUMMARY

In this chapter we set out to consider work relating to each of the multimedia senses - Olfactory (smell), Tactile / Haptic (touch), Visual (sight) and Auditory (sound) - and how this impacts user perception and ultimately user definition of multimedia quality. We proposed an extended model of distributed multimedia, which helped the extensive analysis of current literature concerning video and audio information. We have compared a number of content-level perceptual studies and showed that all previous studies fail to either measure the infotainment duality of distributed multimedia quality or comprehensively incorporate and fully understanding the user-perspective in multimedia quality definition. In conclusion, we show that greater work is needed to fully incorporate and understand the role of the user perspective in multimedia quality definition.

The author believes that a user will not continue paying for a multimedia system or device that they perceive to be of low quality, irrespective of its intrinsic appeal. If commercial multimedia development continues to ignore the user-perspective in preference of other factors, that is, user fascination (i.e. the latest gimmick), then companies ultimately risk alienating the customer. Moreover, by ignoring the user-perspective, future distributed multimedia systems risk ignoring accessibility issues, by excluding access for users with abnormal perceptual requirements.

We have shown that to extensively consider distributed multimedia quality, and to incorporate and understand the user-perspective, it is essential that, where possible, both technical- and user-perspective parameter variation is considered at all quality abstractions of our model, that is, network-level (technical-perspective), media-level (technical- and user-perspective) and content-level (technical- and user-perspective). Furthermore, in order to effectively measure the infotainment duality of multimedia, that is, information transfer and level of satisfaction, the user-perspective must consider both:

- the user's ability to assimilate/understand the informational content of the video.
- the user's satisfaction, both of the objective QoS settings, yet also user enjoyment {assessing the content-level user-perspective}.

If commercial multimedia development effectively considered the user-perspective in combination with technical-perspective quality parameters, then multimedia provision would aspire to facilitate appropriate multimedia, in context of the perceptual, hardware and network criteria of a specific user, thus maximising the user's perception of quality.

Finally, development of quality definition models, as well as user-centric video adaptation techniques (user-perspective personalisation and adaptive media streaming) offers the promise of truly user-defined, accessible multimedia that allows users interaction with multimedia systems on their own perceptual terms. It seems strange that although multimedia applications are produced for the education and/or enjoyment of human viewers, effective development, integration, and consideration of the user-perspective in multimedia systems still has a long way to go….

Chapter 5.20
Leveraging Digital Multimedia Training for At-Risk Teens

Timothy Shea
University of Massachusetts Dartmouth, USA

Craig Davis
The Learning Community Group, USA

INTRODUCTION

The digital divide exists in poor countries and wealthy countries, the country side and cities, and across age groups. Useful solutions when trying to "bridge" the digital divide should include collaboration with local groups in order to better understand and meet their needs (Eglash, 2004). The most far-reaching examples of these community-oriented, information and communication technology (ICT) products and services result in social and economic impacts beyond just the use of technology—sometimes referred to as community informatics. This paper offers one such solution where an extremely cost—effective, community-based ICT program was successfully piloted in order to improve the computer and digital multimedia literacy of at-risk teenagers, provide job skills, open up new career opportunities, and begin to improve the overall economic capital of the community. While piloted in an inner-city, the program represents a best practice that is equally applicable to a small rural setting or to a regional educational initiative. More specifically, this paper describes the project, the curriculum, and—through the use of a questionnaire and video interviews—the students' experiences taking the class.

BACKGROUND

In July and August of 2002, two organizations combined forces to create a special six-week learning opportunity for 15 at-risk teenagers from Boston, Massachusetts' inner-city neighborhoods. The goal for the class was to learn film and computer-based multimedia skills, employ those skills through working in teams, and develop a video documentary. What distinguishes this educational opportunity from others is how computer technology was so actively intertwined in both creating

and enhancing the educational experience.

During the first half of the six-week program, students learned about film history, utilized computer software to create and edit audio, music, and video tracks, and practiced performing the different roles necessary to create a documentary—producer, director, interviewer, camera-person, and editor. The students spent the last three weeks working in teams applying their newly learned skills toward the creation of the documentary. The group assignment was to create an actual documentary. Within each team, each student chose a specific role to focus upon in order to develop a depth of skills in that area.

In an extremely brief amount of time the students, ages 13 to 18, had the opportunity to gain professional media experience and build confidence in a variety of technical and team skills. In the process, they utilized their full range of learning styles—from visual, to auditory, to kinesthetic—and exercised their critical thinking skills both individually and in a team setting as the hundreds of details in developing and refining a multi-track, multimedia documentary were worked through.

The sponsoring group for the class was ABCD (Action for Boston Community Development), a private, non-profit, human services agency promoting self-help for people and neighborhoods that serves over 100,000 low-income Boston-area residents annually (ABCD, 2003). One of ABCD's programs, SummerWorks, is a summer jobs program for Boston's low-income, at-risk youth that has been in place for 35 years. For the summer of 2002, the SummerWorks program provided over 1,300 inner-city youth with paid, 25 hour a week community-based summer jobs that included mentoring, tutoring, and educational support. "SummerWorks enrollees worked in social service agencies, downtown non-profit and government agencies, museums, day camps, libraries, health centers, hospitals, and more. Enrollees also participated in workshops that provide job readiness and skill-building workshops" (ABCD, 2002). One of the SummerWorks 2002 opportunities was a special pilot program.

Fifteen of the students who were hired for ABCD's SummerWorks program were randomly selected to participate in a special skills-building program where they would create a video documentary of ABCD's 2002 SummerWorks Program. The students had no prior knowledge of what they would be asked to create, came from various locations, and had no prior experience working with one another. Only two of the students had any previous experience creating digital video or digital audio. No academic credit was given for participation in the program.

The LCG (The Learning Community Group) of Boston, based on years of experience in the media production industry, designed and built the hardware and selected and customized the software needed to create a video documentary. TheLCG is a technology research and teaching organization dedicated to technology access and mastery by all people, regardless of age, gender, ethnicity or economic bracket. They develop programs that provide emerging technology instruction in a multitude of diverse settings: public and private schools, homeless shelters, libraries, community centers, government agencies and corporate offices (TheLCG, 2003).

The technology component of the class involved the utilization of The LCG Mobile Media Studio (MMS). The MMS is a professional and portable digital audio, video, and music production studio. The MMS is used to create and deliver material for the Internet, broadcast television, or a host of other CD and DVD media distribution formats. The hardware components included a high-performance digital audio/video workstation as well as high-end audio production equipment, including speakers, microphones, and noise-canceling headsets. The software components included professional-level programs for: creating electronic music, recording and editing professional audio tracks, recording and editing professional video tracks, creating CDs, and

streaming media on the Web. Student support for using the MMS included printed guides and an online support community through forums (TheLCG, 2002).

The class met five days a week, from 9 A.M. until 3 P.M., for six weeks. The course was taught by a master instructor and film producer from TheLCG and assisted by a staff member from ABCD.

THE CURRICULUM

The overall objective of the six-week program was to develop a 25-minute, multimedia documentary about ABCD's 2002 SummerWorks program. Curriculum objectives leading to the overall objective included:

- Study film history
- Comprehend and use film language
- Gain media awareness
- Gain experience in executing every production role on a film or video set
- Develop film and video production skills
- Use digital video editing technologies fluidly
- Hone the art of storytelling
- Develop skills for working in teams

The curriculum was broken down into modules as described in the following sections.

Module 1, Week 1: Objective = Crash Course in Film History / Photography / Cinematography / Film Language

The first week had four major components:

- Description of class/job objectives
- A crash course on film history, photography, cinematography, and film language
- Initial exposure to the cameras and the video editing software
- Team building and interviewing skills

Although the crash course in film and production concepts was considered "too much like high school" by some in the class, they were able to apply the concepts taught in class effectively. One assignment challenged the students to find examples of the concepts on TV. Students accurately identified:

- An Eisenstein montage within a music video
- The rule of thirds being used on a game show
- Joseph Campbell's monomythic arc being followed in an episode of "SpongeBob Squarepants"

After one week, the students were ready to work as a production team to develop their first film short.

Module 2, Week 2 & 3: Cross-Job Training

During weeks 2 and 3, the class was broken evenly into two groups. The students, in essence, became employees. The students rotated from producer, director, interviewer, camera-person, and editor, trying every position at a number of sites around the Boston area. For example:

- Producers and directors contacted the site they visited, set up an arrival time, and scouted the location beforehand to get ideas of how to capture the site
- Camera-people worked on video taping locations and gained experience using the camera
- Editors imported the resulting footage and edited it to music in order to gain experience in using the editing software

Students typically visited one site per day.

Module 3, Weeks 4, 5 & 6: Working on the Final Project: Creating the Documentary of ABCD's Boston SummerWorks 2002.

In week 4, each student ranked which job they were the most confident at and the instructor— based on observation and student preference—formed the production staff that stayed in place until the end of the project. From this point on, the instructor moved from a teacher role to an advisor role. Students decided where they wanted to visit, who to contact and what to ask. They became a fully functional production team.

Weeks 4 and 5 were spent recording footage from 10 different sites. Week 6, the final week, was spent doing post-production work—directors, producers, and interviewers wrote thank-you letters to the sites visited while the camera-people catalogued the tapes and footage. The class voted on their favorite sites and determined an order for the documentary. The segments were then assembled and the final product was shown to various audiences.

The Final Product

The final product was a 26-minute, professional quality, multi-track video documentary of ABCD's 2002 SummerWorks program—produced in only three weeks. The documentary can be viewed from http://www.thelcg.com/research.htm.

The video in its final form, complete with insightful interviews, professional visual composition, succinct story telling, and sophisticated editing is a notable achievement. However, the student's innate capacity and understanding of syncopation elevates the subject matter producing a final product that rivals a professional production. The digital video comprehension that was gained empowers the participants offering a new medium for self-expression.

Assessment of the Student's Work

Several forms of assessment were used to evaluate each student's progress throughout the program:

- Students kept an ongoing journal for recording their thoughts and comments.
- During the third week, a mid-program assessment was conducted. "One-on-one" meetings were conducted between the instructor, the ABCD assistant, and each student. Each student was given formal feedback, to gauge their excitement, dedication and personal investment in the project, as well as allowing them the opportunity to make suggestions and requests. This mid-program assessment was extremely effective in bridging the academic mode with the production studio end.
- A final assessment was conducted through individual video reflections and a round table discussion.The individual video reflections gave the participants the opportunity to reflect on the process. In addition to this, the instructor and the ABCD assistant conducted a round table discussion about the process and the successes and failures that came with it. Students were not easy on themselves either. At this time they pointed out that they wished they could have had more time to perfect the audio in both recording and editing. These assessments were effective due to the ability of the students to make mature, professional, and sometimes poignant suggestions.

Relating the Course Curriculum to the State of Massachusetts' Language Arts Framework

To make the program relevant to the student's middle school and high school education, the course curriculum was designed to fulfill a num-

ber of the specific learning standards for grades seven through 12 as established in the state-wide curriculum frameworks by the Massachusetts Department of Education (Massachusetts Language Arts Framework, 2001). The course curriculum related specifically to the Massachusetts Language Arts Framework, especially for the following standards: media production; analysis of media; discussion; questioning, listening, and contributing; oral presentation; writing; consideration of audience and purpose; and revising. Details of how the program's curriculum relates to the Massachusetts Language Arts Framework are available from the authors.[1]

THE STUDENT EXPERIENCE

Students became very close through this process. By the nature of the project, creating a documentary, each group had to work together as a cohesive whole as well as take responsibility for their own actions and duties. By the end of the program they were more than classmates, they had become a tight-knit family as evidenced by the hugs and tears shared on the last day and their continued attendance beyond their final payday. As the instructor put it, "Throughout the process I witnessed students staying extra hours without pay four out of five days a week, not just because of the equipment but because they were excited to be creating a product, and enjoyed following its progress. Even once there was nothing else to do, students continued to come in at 9 A.M. and stay until 3 because they wanted it to still be a part of their life." All of the students came in at least once after the program was concluded. Six of the 15 students appeared everyday for two weeks after the program concluded.

Data was collected about the student experience through two means. First, a 15-question student evaluation form made up primarily of 1-to-5 Lickert scale questions that provided space for an open-ended explanation for each answer was administered during the last week of class. Secondly, nine of the students were interviewed individually about their class experiences. Segments of those interviews can be found at http://www.thelcg.com/research.htm.

Questionnaire Results

Twelve out of the 15 students in the class completed the questionnaire. A copy of the questionnaire, based upon a validated instrument from ASTD's 2002 Learning Outcomes Report, is available from the authors (ASTD, 2002). The questions used a 5-point Likert scale, where a "1" meant "Strongly Disagree," "2" meant "Disagree," "3" meant "Neither," "4" meant "Agree," and "5" meant "Strongly Agree."

Overall, students were *very satisfied* with the course (Q15), with an average response of *4.4* (Between Agree (4) and Strongly Agree (5)). Interesting results from the other questions include:

Student's Previous Experience

Student's previous computer experience (Q1 & Q2) was quite varied. Average student use of the computer before starting the class clumped into two groups:

- 50% used the computer six or fewer hours per week
- 33% used the computer 21 or more hours per week

Most of the computer use was for the expected—e-mail and chat, writing papers, and surfing the Internet.

Class Organization and Delivery

- **Understanding course objectives:** Students clearly understood the course objectives and felt the course met the objectives (Q5

& 6, Mean of 4.5 and 4.4, respectively). One student's comment, "I knew what I was responsible for," was representative.

- **Teaching effectiveness:** Students felt the instructor's approach to "teaching and presentation of materials made it easy for me to learn" (Mean of 4.4). Students enjoyed the "hands-on" aspect and being able to "get out and do things." Two students mentioned the program "started off like a class," "being taught and told," and how they liked it better once they started using the software.
- **Pace:** Most students felt they had enough time (Q8), but 17% (2 of 12) did not (answered 1 or 2: strongly disagree or disagree). Several comments mentioned learning a lot but wanting more time.
- **Effectiveness:** All but one student answered "Agree" (4) or "Strongly Agree" (5) to the two questions about what they learned: whether they learned something in the class (Q11) and whether they are confident with what they learned after the class was completed (Q12). One student emphasized the point by saying, "It is on my resume." Another said, "I feel like I could teach someone else." Finally, based on the experience of going out and interviewing people, one student now has "more confidence talking to people I don't know."

Impact on Job Skills and Future Job Aspirations

Seventy-five percent answered "Agree" or "Strongly Agree" to whether they see themselves "getting a job where I can use the knowledge and/or skills gained through this course" (Q14). One student specifically mentioned wanting "to work with film when I get older," another "wants to be a producer." In fact, making use of the skills that he learned and honed during the six-week program, one of the students has begun his own business as a wedding videographer. Another student has completely changed her career goals and now wants to become a producer of documentaries, film, and television. Before this summer she was planning on attending a two-year community college. Now, she has already begun investigating film schools in the area and researching their criteria for incoming freshman. Another student submitted the documentary in a competition for an artistic grant. More than 1,000 students applied and he was awarded the artistic grant.

CONCLUSION

Overall, the results are very positive. Put simply, the two immediate objectives of this ICT program were *to inform* and to have the students *perform*. Students needed to quickly learn film and production concepts as well as hands-on skills such as using a video camera and video editing software. TheLCG's MMS, or Mobile Media Studio, provided a field-tested set of hardware and software that is robust and reasonably easy to learn and use. TheLCG's curriculum, tested and refined over a number of years, provided an effective process for high-school-age students (and even younger) to learn the conceptual foundation, the hands-on skills, as well as the communication, team-building, and design skills needed to create a high-quality video documentary within a few weeks. From the results of the end-of-the-class questionnaires and interviews, students were engaged and they enjoyed the many challenges of this course. As one student said, "It was fun and didn't seem like a hard job, just interesting."

In the long term, students took one large step towards succeeding in the 21st century by becoming more literate in both computers and computers' new language, digital multi-media. For the community, economic capital is enhanced through new job skills and career opportunities. Social and cultural capital grows by understanding new ways of expression and new ways to record and distribute history. For example, once people in a

community know how to use digital video and audio they can create their own documentaries and Internet TV stations.

As a result of the successes of this pilot program, ABCD decided to redesign its University High School's computer lab into a full digital media production studio in which every computer is a Mobile Media Studio. In addition, some of the computers now possess professional music recording and DVD authoring capabilities. ABCD and theLCG are also exploring the creation of a dedicated room to be used for regular Internet TV and Radio broadcasts as well as music production.

KEY TERMS

Community Informatics: The use of information and computer technologies (ICT) in communities in order to impact communities socially and economically.

Critical Thinking: An active and systematic cognitive strategy to examine, evaluate, and understand complex issues and personal choices, pose provocative questions, correctly frame and then solve problems, and make decisions on the basis of sound reasoning and valid evidence. This competitive edge requires both rigorous analysis and nimble imagination. (Definition based on www.centerforcriticalimpact.com/definitions.htm definition.)

Learning Style: An individual's unique approach to learning based on strengths, weaknesses, and preferences. Though experts do not agree how to categorize learning styles, an example of a categorization system is one that separates learners into auditory learners, visual learners, and kinesthetic (feeling) learners. (Definition based on e-learningguru.com/gloss.htm definition.)

Likert Scale: A rating scale, typically 1 through 5 or 1 through 7, measuring the strength of agreement with a clear statement. Often administered in the form of a questionnaire used to gauge attitudes or reactions. (Definition based on http://www.isixsigma.com/dictionary/ Likert_Scale-588.htm definition.)

Multi-Media: The use of computers to present text, graphics, video, animation, and sound in an integrated way. Long touted as the future revolution in computing, multi-media applications were, until the mid-90's, uncommon due to the expensive hardware required. With increases in

performance and decreases in price, however, multi-media is now commonplace. Current PCs and PC operating systems are both capable and specifically tuned in order to accommodate the rapidly growing demand for multi-media, especially in the consumer market. (Definition based on www.webopedia.com definition.)

Multi-Track: In traditional recording technology, the ability to layer multiple different audio signals at once. In MIDI software, the ability to layer numerous MIDI data streams, including multiple audio tracks, a video track, etc. (Definition based on http://www.cakewalk.com/tips/desktop-glossary.asp definition.)

Streaming Media: The process by which multi-media files (e.g., audio files, video files, and music files) are delivered through the Internet. Such files are often very large, tens or hundreds of megabytes in size.

Syncopation: A style used in order to vary position of the stress on notes so as to avoid regular rhythm. Syncopation is achieved by accenting a weak instead of a strong beat, by putting rests on strong beats, by holding on over strong beats, and by introducing a sudden change of time signature. This style of composition was exploited to fullest capabilities by jazz musicians, often in improvisation. (Definition based on www.geocities.com/BourbonStreet/Delta/4688/ glossary.htm definition.)

ENDNOTE

[1] The authors thank Ruth Joseph for her help with The State of Massachusetts' Language Arts Framework.

This work was previously published in Encyclopedia of Developing Regional Communities with Information and Communication Technology, edited by S. Marshall, W. Taylor, and X. Yu, pp. 475-480, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Section 6

Managerial Impact

This section presents contemporary coverage of the more formal implications of multimedia technologies, more specifically related to the corporate and managerial impact of the core concepts of multimedia, and how these concepts can be applied within organizations. The design and implementation of multimedia advertising is the focus of this section, which provides a how-to guide for multimedia business and commerce. The managerial research provided in this section allows executives and employees alike to understand the role of multimedia technology in business.

Chapter 6.1
Distanced Leadership and Multimedia

Stacey L. Connaughton
Purdue University, USA

INTRODUCTION

At the dawn of the 21st century, more and more organizations in various industries have adopted geographically dispersed work groups and are utilizing advanced technologies to communicate with them (Benson-Armer & Hsieh, 1997; Hymowitz, 1999; Townsend, DeMarie & Hendrickson, 1998; Van Aken, Hop & Post, 1998). This geographical dispersion varies in form. For example, some organizations have adopted "telecommuting," in which members may work at home, on the road and/or at the office (Hymowitz, 1999). Other organizations have created teams that are globally dispersed. A leader located in Palo Alto, California, for example, may be responsible for coordinating employees in Belgium, China and Mexico.

This article examines the role of communication and multimedia in leading people across time and space. To do so, I first note the significance of distanced work relationships; then, outline various conceptualizations of "distance" evident in the literature; next, discuss the role of multimedia in those relationships; and conclude by forecasting future trends. Throughout the article, the term "distanced leadership" is used to refer to leadership in geographically dispersed contexts.

THE PROLIFERATION OF DISTANCED LEADERSHIP

New organizational forms have become increasingly prevalent in recent years. Indeed, many contemporary organizations and teams span time and space. Physical separation of organizational and/or team members is a defining characteristic of virtual organizations and teams (Jarvenpaa & Leidner, 1998; Majchrzak, Rice, King, Malhotra & Ba, 2000; Warkentin, Sayeed & Hightower, 1997; Wiesenfeld, Raghuram & Garud, 1999), geographically dispersed teams (Connaughton & Daly, 2003, 2004a, 2004b; Shockley-Zalabak, 2002), dispersed network organizations (Rosenfeld, Richman & May, 2004) and telework operations (Hylmo & Buzzanell, 2002; Leonardi, Jackson & Marsh, 2004; Scott & Timmerman, 1999). In these forms, the organization or team is constituted in its interaction and formal and

informal networks. By 2005, 20% of the world's work force is expected to work virtually (Prashad, 2003). Indeed, scholars have called on leadership scholarship to "stretch its boundaries to match the elastic nature of global work" (Davis, 2003, p. 48).

Geographical dispersion affords organizations both opportunities and challenges to both business and communication. Table 1 summarizes these issues as they often appear in the literature.

On the one hand, geographically dispersed teams present organizations with many opportunities. They can help organizations maximize productivity and lower costs (Davenport & Pearlson, 1998). And, they can enable organizations to serve international customers and capitalize on globally dispersed talent (Majchrzak, Rice, King, Malhotra & Ba, 2000; Zaccaro & Bader, 2003). Ideally, this geographical dispersion is designed to foster productivity from, and cooperation among, organizational members, just as if they were co-located with one another (see Handy, 1995; Upton & McAfee, 1996).

Yet geographical dispersion also poses some challenges, specifically with regard to leadership. Previous research indicates that (a) a leader's "social presence" may be more difficult to achieve in distanced settings (Kiesler & Sproull, 1992; Warkentin, Sayeed & Hightower, 1997); (b) trust among leaders and team members may be swift yet fleeting (Jarvenpaa, Knoll & Leidner, 1998); (c) members' identification with the team, organization, and leader may be challenged over distance (Connaughton & Daly, 2004b); and (d) communication among leaders and team members may be complicated by diverse ethnic, communication and organizational backgrounds (Cascio, 1999; Cascio & Shurygailo, 2003).

These challenges are put into perspective when one compares what may take place in physically proximate offices to what often happens in distanced work relationships. It has been suggested that co-located office settings provide more opportunities for organizational members to communicate frequently and spontaneously with each other; they allow for potential to interact immediately for troubleshooting; they foster a forum in which to directly access information; and they enable the development and maintenance of relationships (Davenport & Pearlson, 1998). Often, leaders who are co-located with their team members develop and energize relationships with their team through informal as well as formal interaction. In globally dispersed organizations, however, there may be fewer opportunities to informally communicate, leaving some distanced employees feeling isolated from their leaders and from events that take place at the central organization (Van Aken, Hop & Post, 1998; Wiesenfeld, Raghuram & Garud, 1998).

Table 1. Opportunities and challenges of globally dispersed teams

Opportunities	Challenges
•Reduce costs •Serve international customers/clients •Integrate Global Talent•	•Time zone differences •Language differences •Varied communication norms •Limited face-to-ace Contact

CONCEPTUALIZATIONS OF "DISTANCE"

Research on distanced work relationships, including that related to leadership, defines "distance" in different ways. Some scholars examine physical distance, when individuals and leaders are separated by geography (see Antonakis & Atwater, 2002; Kerr & Jermier, 1978). Other scholars investigate social or psychosocial distance, which often refers to perceived differences in status, rank, authority, social standing and power among leaders and followers, all of which may affect the intimacy and social interactions that take place between leaders and followers (see Antonakis & Atwater, 2002; Napier & Ferris, 1993).

Some researchers conceive of physical distance and social distance as related constructs, functioning in a similar manner (see Howell & Hall-Merenda, 1999). Others argue that physical distance and social distance are distinct and should be considered as separate constructs in research. Among them, Antonakis and Atwater (2002) also add a third dimension of distance, perceived interaction frequency, which they define as the perceived degree to which leaders interact with their followers. They propose that physical distance, social distance and perceived interaction frequency are measurable and are separate dimensions, each of which describes an element of "distance" in dispersed work relationships.

Other research examines how individuals perceive distance in geographically dispersed work contexts. For example, in a study of 46 teleworkers in a variety of industries, Leonardi, Jackson and Marsh (2004) argue that these individuals *manage* distance in various ways. The authors conclude that dispersed individuals do not all perceive distance similarly, and that they manipulate the fact that they are geographically distant from others in order to satisfy individual needs. In the authors' words, "… distance is much more than a mere outcome of the use of ICTs; it is rather a tool virtual team members can use to manage their relationships with their coworkers and their organizations" (p. 169).

MULTIMEDIA AND DISTANCED LEADERSHIP

The published work on multimedia, communication technologies and dispersed leadership can be grouped into two broad categories: that which discusses effective practices for using media to forge connections across time and space; and that which addresses key assumptions in previous research, particularly with respect to the perceived necessity of face-to-face interaction and to the impact physical distance has on work relationships.

Effective Practices

Some published work advances effective practices, highlighting various ways that leaders can utilize multiple media to foster connections with distanced employees across time and space. Among the recommendations, researchers have noted: (a) the creation of Web sites, where project managers can post their "lessons learned" and share effective practices with leaders at other sites; (b) the utilization of electronic forums to advertise what "works" in the regions and to propagate those ideas to headquarters and other remote sites; and (c) the development of internal electronic bulletin boards (one devoted to leaders; another devoted to members), where project leaders and team members can ask questions and receive suggestions from other project leaders and members (see Burtha & Connaughton, 2004; Connaughton & Daly, 2003). Majchrzak, Malhotra, Stamps and Lipnack (2004) note that these virtual work spaces should be considered more than "networked drives with shared files" (p. 134). These virtual work spaces must be accessible to everyone at all times, and a place where the team is reminded of its mission, purpose, decisions and future objectives.

In addition to explaining effective practices, existing research advances propositions about which media function particularly well to achieve various leadership objectives. One of these works is based on a series of interviews with distanced leaders about what media they perceive to be effective in executing various leadership functions across time and space (Connaughton & Daly, 2003). Distanced leaders interviewed in this study perceive that face-to-face communication is optimal for achieving objectives, but acknowledge that it is not always possible when employees and team members are dispersed. The research findings suggest that face-to-face communication is best used to set vision, reach policy decisions and begin to build relationships. When face to face is not an option, regularly scheduled telephone calls are most effectively used

to exchange important task-related information, maintain relationships, appraise performance and coordinate teams. And, electronic mail (e-mail) is most effective to exchange technical information, give specific directions, update interested parties and maintain relationships. (For further discussion of technologies and virtual contexts, see Contractor & Eisenberg, 1990; Ferris & Minielli, 2004; Haythornthwaite & Wellman, 1998; Majchrzak, Rice, King, Malhotra & Ba, 2000.)

Addressing Assumptions of Previous Research

Recent work on distanced leadership has begun to carefully consider two assumptions about working in dispersed contexts. Those assumptions are: (a) that face-to-face communication is related to organizational outcomes; and (b) that physical distance necessarily is an impediment to productive and satisfying work relationships.

- **Assumption:** *Face-to-face communication is critical.* It has been argued that, despite the existence of new media, face-to-face communication is still vitally important to achieving organizational outcomes (Cohen & Prusak, 2001). Some scholarship compares experiences of individuals working proximately with one another (and who can communicate face to face) with individuals working apart from one another. For instance, Warkentin, Sayeed and Hightower (1997) found that face-to-face group members perceive greater team cohesion, and more satisfaction with both the group interaction process and group outcomes than did their distanced counterparts. One conclusion that could be drawn from this research is that individuals prefer to work in close proximity to leaders.

  Zack (1994) and Alge, Wiethoff and Klein (2003) found, however, that although initial face-to-face interactions are quite helpful for teamwork, as time goes on and team members come to better understand one another, mediated communication such as e-mail could be used to accomplish tasks. Scholars are also beginning to explore the processes of teams who never meet face to face and yet still function (Bell & Kozlowski, 2002; Davis, 2003). Continued research in this area may challenge the assumption that face-to-face communication is a necessary ingredient of effective distanced work relationships.
- **Assumption:** *Physical distance necessarily challenges work relationships.* Previous research on distanced work relationships assumes that physical distance complicates performance and leader-follower relationships because distance makes it difficult for leaders to engage in relational and task-related behaviors with followers (see Kerr & Jermier, 1978; Olson & Olson, 2000). Often, scholars contrast distanced leadership with proximate leadership, and claim that physical proximity enables more effective communication between leaders and followers (Yagil, 1998).

  However, the perceived *accessibility* of people in the distanced relationship may matter in predicting important outcomes as well (Cascio & Shurygailo, 2003; Napier & Ferris, 1993). Perceived accessibility refers to the distanced employees' perception that they can contact or reach their leader when so desired. Indeed, previous research has suggested that frequent interaction is critical to establishing a feeling of connection across time and space (Antonakis & Atwater, 2002; Connaughton & Daly, 2004b; Leonardi et al., 2004). And, distance may be perceived in positively valenced ways. As Leonardi et al. (2004) have argued, distance may be strategically managed by some distanced leaders and employees to be an *opportunity* rather than a necessary impediment to work relationships.

FUTURE TRENDS

Thousands of companies in diverse industries now have distanced leaders (see Apgar, 1998; Bryan & Fraser, 1999; Hymowitz, 1999; Lipnack & Stamps, 1997; McCune, 1998). And these leaders face the complex task of managing people who are separated from organizational headquarters by time and space.

Future investigations should consider related organizational trends. For instance, does leadership of geographically dispersed ad hoc teams (that are assembled for short-term projects) differ from the type of distanced leadership described here? If so, how? How does one manage contractors and consultants (who may not have loyalty to the organization) from afar? And, given trends in international customer service, how do organizations effectively serve and lead customers from afar?

Future researchers should also continue to develop theoretical models of distanced leadership as well as continue to conduct empirical work on these and other variables. For instance, it will be important to investigate whether actual physical distance *per se* is the most essential defining feature of a dispersed relationship. Instead, perhaps *physical distance* and *access* to leaders and team members function together to affect relationships and outcomes.

Another important issue for both scholars and practitioners is the assumption made by many that distanced teams have more difficulty than face-to-face teams. That presumption warrants empirical testing. The leaders we have talked with in our research have been quite insistent that face-to-face exchanges offer them the optimal medium for communication. None of the leaders interviewed consider mediated technologies as being effective for handling personnel issues, conflicts and relational development. Yet a question arises: Are these responses tied to levels of experience and training with the technologies, generational differences or other factors? It may be that with more experience using various technologies for communication and more perceived expertise with them that people's preference for face-to-face communication for various tasks may diminish. Future research may find that some distanced employees actually prefer mediated communication with their leader.

CONCLUSION

As organizations become more global, as talent becomes more dispersed and as technologies enable people to do far more from afar, distanced leadership and dispersed work relationships will continue to be important to organizations in the 21st century. Given those trends, the issues discussed in this chapter will become ever more critical for scholars and practitioners to consider.

KEY TERMS

Accessibility: An individual's perception that he/she can contact or reach his/her leader when so desired.

Dispersed/Distributed Teams: Teams separated by some degree of physical distance.

Distanced Leadership: Leadership of a team or organizational members that are separated by some degree of time and distance from their leader.

Identification: Identification is the process in which an individual comes to see an object (e.g., an individual, group, organization) as being definitive of oneself and forms a psychological connection with that object. Although scholars have offered a variety of conceptual definitions for identification, we view it as a communicative process, rooted in discourse and constituting a communicative expression of one's identity.

Social Presence: The perception of physical and/or psychological access to another. Social presence theory often focuses on the aspects of communication media that permit people to connect or "be present" with others and the theory sees some degree of social connectedness as crucial to work relationships.

Chapter 6.2
Leadership Competencies for Managing Global Virtual Teams

Diana J. Wong-MingJi
Eastern Michigan University, USA

INTRODUCTION

The demand for leadership competencies to leverage performance from global virtual teams (GVTs) is growing as organizations continue to search for talent, regardless of location. This means that the work of virtual leaders is embedded in the global shifting of work (Tyran, Tyran & Shepherd, 2003). The phenomenon began with the financial industry as trading took place 24/7 with stock exchanges in different time zones. It is expanding into other industries such as software programming, law, engineering, and call centers. GVTs support the globalization of work by providing organizations with innovative, flexible, and rapid access to human capital. Several forces of competition contribute to the increasing adoption of GVTs, including globalizing of competition, growing service industries, flattening of organizational hierarchies, increasing number of strategic alliances, outsourcing, and growing use of teams (Pawar & Sharifi, 1997; Townsend, DeMarie & Hendrickson, 1998). The backbone of GVTs is innovation with computer-mediated communication systems (CMCSs). Advances with CMCSs facilitate and support virtual team environments.

Leaders of GVTs have a pivotal role in mediating between the internal team processes and the external environment. Leadership competencies also are necessary to keep up with the evolving demands placed on GVTs. Previously, GVTs focused primarily on routine tasks such as data entry and word processing. More recently, the work of GVTs began to encompass non-routine tasks with higher levels of ambiguity and complexity. By tackling more strategic organizational tasks such as launching multinational product, managing strategic alliances, and negotiating mergers and acquisitions, GVTs contribute higher added value to a firm's competitive advantage. As a result, leadership competencies for GVTs become more important in order to maximize the performance of GVTs.

Leadership competencies encompass knowledge, skills, abilities, and behaviors. The following discussion reviews the context, roles, and responsibilities of managing GVTs, identifies five broad categories of GVT leadership competencies, and outlines significant future trends.

BACKGROUND

In order to address specific leadership competencies for GVTs, it is important to understand the virtual workplace context. "Global virtual teams being a novel organizational design, it is very important to maximize the fit between team design and their stated intent" (Prasad & Akhilesh, 2002, p. 104). Currently, many organizations are deploying the use of GVTs much more rapidly than the collective understanding of their unique characteristics, dynamics, and processes. Anecdotal evidence exists about the difficulties and poor performance of GVTs. But the expectations of flexibility, accessing expertise regardless of geographical location, and speed of fulfilling organizational goals continue to drive the growth of GVTs (Gibson & Cohen, 2003).

GVTs have similarities and differences when compared with traditional teams (Maznevski & Chudoba, 2000). The similarities include being guided by shared goals, working on interdependent tasks, and sharing responsibilities for outcomes. The differences are the collocation and synchronous communication of traditional teams vs. geographical dispersion and often asynchronous communication for virtual teams. The stability of GVTs depends on the project and the team's role in fulfilling the organizational purpose. Thus, GVT leaders may be working with a project orientation or indefinite perpetual organizational responsibilities, which shape the lifecycle of the team.

Effective GVT leaders must manage magnified ambiguities and complexities compared to traditional team leaders. Prasad and Akhilesh (2002) define a GVT as "a team with distributed expertise and that spans across boundaries of time, geography, nationality, and culture" (p. 103). They address a specific organizational goal with enhanced performance and operate with very little face-to-face interaction and predominantly computer mediated and electronic communication. As a result, leaders of GVTs need to address unique challenges that stem from spatial distances, asynchronous communication, multicultural dynamics, and national boundaries in a virtual environment.

Established research findings on teams indicates that leaders have a critical influence on team performance outcomes (Bell & Kozlowski, 2002; Fjermestad & Hiltz, 1998-1999; Kayworth & Leidner, 2001-2002). In general, team leaders have two critical functions: team development and performance management. Some general leadership tasks for managing teams include developer of team processes, facilitators of communications, and final arbiter for task completion (Duarte & Tennant-Snyder, 1999). Bell & Kozlowski (2002) offer a typology of virtual teams based on four characteristics—temporal distribution, boundary spanning, lifecycle, and member roles—that are mediated by task complexity. These characteristics imply that effective management of GVTs requires a portfolio of leadership competencies to address the following responsibilities: (1) provide clear direction, goals, structures, and norms to enable self regulation among team members; (2) anticipate problems; (3) monitor the environment and communicate changes to inform team members; (4) design back-up plans to buffer changes in environmental conditions; (5) develop feedback opportunities into team management structure for regular performance updates; (6) diagnose and develop appropriate team development through a virtual medium; (7) diagnose the translation of self-regulation methods across different boundaries; (8) modify behaviors and actions according to the particular situations to support the communication of worldviews among team members and build a third culture; and (9) identify and communicate team member roles to create role networks.

An important component of the GVT leader's work environment is the virtual "rooms" for the team's interactions. A wide range of products offers differing capabilities. For example, Groove Client 2.5 and Enterprise Management from

Groove Networks, Workgroup Suite 3.1 from iCohere, and eRoom 7.0 from Documentum are products that facilitate how virtual teams can navigate through cyberspace (Perey & Berkley, 2003). Large firms in the auto industry use a commercial B2B product called ipTeam from NexPrise to support collaboration among geographically dispersed engineering team members. IBM offers the IBM Lotus Workplace Team Collaboration 2.0. Free Internet downloads such as NetMeeting from Microsoft also are available to facilitate virtual meetings. Competitors include FarSite from DataBeam Corp, Atrium from VocalTec Communications Ltd., ProShare from Intel Corp, and Conference from Netscape. The list of available CMCS products continues to grow and improve with more features that attempt to simulate face-to-face advantages. As a result, part of managing GVTs includes evaluating, selecting, and applying the most appropriate CMCS innovations to support team interactions. Adopting CMCS needs to account for work locations, members involved, technological standardization, work pace, work processes, and nature of work in the organization. In sum, a GVT leadership portfolio must be able to manage CMCSs, diverse team members, team development, and work flow processes.

GVT LEADERSHIP COMPETENCIES

Competencies for GVT leaders can be classified into five broad categories: CMCS proficiency, work process design, cross-cultural competencies, interpersonal communication, and self-management. The five groups of competencies are interrelated. For example, a high degree of expertise with CMCSs without the necessary interpersonal communication competencies likely will lead to conflicts, absentees, and negative productivity.

First, GVT leaders need to have technical proficiency with innovations in CMCS in order to align the most appropriate technological capabilities with organizational needs. Technical knowledge of CMCSs and organizational experience enables GVT leaders to align technology with strategic organizational goals. Organizational experience provides GVT leaders with insights regarding the organizational work task requirements, strategic direction, and culture. This tacit knowledge is rarely codified and difficult to outsource compared to explicit knowledge. This implies that firms should provide training and professional development for leaders to increase CMCS proficiency.

Second, GVT leaders require work process design competencies to manage the workflows. Managing global virtual workflows depends on leadership skills to structure teams appropriately for subtasks, monitor work progress, establish expectations, maintain accountability, build a cohesive team, motivate team members, create trust, develop team identity, and manage conflicts (Montoya-Weiss, Massey & Song, 2001; Pauleen & Yoong, 2001; Piccoli & Ives, 2003). GVT leaders also need to devote considerable attention to performance management, especially in prototypical teams where there may be information delays and members are decoupled from events. GVT leaders can employ temporal coordination mechanisms to mitigate negative effects of avoidance and compromise in conflict management behavior on performance (Montoya-Weiss, Massey & Song, 2001). During the launching of teams, GVT leaders need to use appropriate team building techniques (e.g., discussion forums) to become acquainted and to establish positive relationships (Ahuja & Galvin, 2003; Prasad & Akhilesh, 2002). The lifecycle of virtual teams tends to proceed through four stages of group development that entails forming with unbridled optimism, storming with reality shock, norming with refocus and recommitment, and performing with a dash to the finish (Furst et al., 2004). The lifecycle of virtual teams influences the development of team spirit and identity, which is more important with continuous virtual team lifecycle. Its membership is relatively more stable compared to temporary projects. Task com-

plexity places constraints on team structure and processes (Prasad & Akhilesh, 2002). Relatively simple tasks have less need for stable internal and external linkages, common procedures, and fixed membership, compared to more complex tasks. Leaders need to assert flexible, collegial authority over tasks and act as empathetic mentors to create collaborative connections between team members (Kayworth & Leidner, 2001). In sum, managing the work process design requires dealing with paradoxes and contradictions to integrate work design and team development.

Third, GVT leaders also require cross-cultural competencies, more specifically identified as global leadership competencies. "Successful virtual team facilitators must be able to manage the whole spectrum of communication strategies as well as human and social processes and perform these tasks across organizational and cultural boundaries via new [information and communication technologies]" (Pauleen & Yoong, 2001, p. 205). Developing global leadership competencies entail a sequence from ignorance, awareness, understanding, appreciation, and acceptance/ internalization to transformation (Chin, Gu & Tubbs, 2001). The latter stages involve development of relational competence to become more open, respectful, and self-aware (Clark & Matze, 1999). Understanding cultural differences helps to bridge gaps in miscommunication. Identifying similarities provides a basis for establishing common grounds and interpersonal connections among team members. Leaders who are effective in leading across different cultures have relational competence to build common grounds and trust in relationships (Black & Gregersen, 1999; Gregersen, Morrison & Black, 1998; Manning, 2003). By increasing trust, leaders can connect emotionally with people from different backgrounds to create mutually enhancing relationships (Holton, 2001; Jarvenpaa & Leidner, 1999). The connections are critical to construct a high-performing team (Pauleen, 2003). A key to cross-cultural leadership competencies for GVTs is projecting them into a virtual environment. This is related to CMCS proficiency, which supports the communication cross-cultural competencies in a virtual environment. Cross-cultural competencies also are closely interrelated with both interpersonal communication competencies and self-management to effectively lead GVTs.

Fourth, interpersonal communication competencies do not necessarily encompass cross-cultural competencies. But cross-cultural competencies build upon interpersonal communication competencies. Strong interpersonal communication enables GVT leaders to span multiple boundaries to sustain team relationships (Pauleen, 2003). An important communication practice is balancing the temporal dimension and rhythm of work to stay connected (Maznevski & Chudoba, 2000; Saunders, Van Slyke & Vogel, 2004). Interpersonal communication competencies for GVT leaders need to focus on the human dimension. For example, GVT leaders need to be conscious of how they "speak," listen, and behave non-verbally from their receiver's perspective without the advantage of in-the-moment, face-to-face cues. This provides the basis for moving from low to higher levels of communication—cliché conversation, reporting of facts about others, sharing ideas and judgments, exchanging feelings and emotions, and peak communication with absolute openness and honesty (Verderber & Verderber, 2003). Interpersonal communication skills of GVT leaders should, at a minimum, support the exchange of ideas and judgments. When GVT leaders demonstrate "active listening" online, team members likely will move toward higher levels of communication. Active listening in GVTs can be demonstrated with paraphrasing, summarizing, thoughtful wording, avoiding judgment, asking probing questions, inviting informal reports of progress, and conveying positive respectful acknowledgements. Another aspect of interpersonal communication competencies for GVT leaders is establishing netiquette, which establishes ground rules and team culture. GVT leaders can strategi-

cally develop their interpersonal communication competencies to socialize team members, build team connections, motivate team commitment, resolve conflicts, and create a productive team culture to achieve high performance outcomes (Ahuja & Galvin, 2003; Kayworth & Leidner, 2001-2002).

Finally, a GVT leader's self-management competencies fundamentally influence the development of the four competencies. GVT leaders need to manage their self-assessment and development to acquire a portfolio of competencies. A high level of emotional intelligence enables GVT leaders to engage in self-directed learning for personal and professional development. Self-management refers to adaptability in dealing with changes, emotional self-control, initiative for action, achievement orientation, trustworthiness, and integrity with consistency among values, emotions and behavior, optimistic view, and social competence (Boyatzis & Van Oosten, 2003). The development of GVT leaders with self-management can positively influence team performance by rectifying areas of their own weaknesses and reinforcing their strengths.

In summary, GVTs provide organizations with an important forum for accomplishing work and gaining a competitive advantage in global business. Technological innovations in CMCSs provide increasingly effective virtual environments for team interactions. A critical issue focuses on the GVT leader with the necessary portfolio of competencies. Research and understanding of leadership competencies for managing GVTs are at a nascent stage of development.

FUTURE TRENDS

Researchers need to delve into this organizational phenomenon to advance best practices for multiple constituents and help resolve existing difficulties with GVTs. Understanding leadership competencies for managing GVTs depends on a tighter coupling in the practice-research-practice cycle. Given turbulent competitive environments and more knowledge-based competition, research practices need to keep up with the rapid pace of change. At least three important trends about GVTs need to be addressed in the future.

First, GVTs will continue to grow in strategic importance. An important implication is that GVTs will face greater complexities and ambiguities. Furthermore, GVT leaders will have little or no contextual experience with their team members' locations. This is a significant shift when globe-trotting managers often have face-to-face time with their team members in different locations. Thus, the need to create authentic emotional connections and accomplish the task at hand through multiple CMCSs will continue to be important
