by Volume

Volume I

Section 1. Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of multimedia technologies. Chapters found within these pages provide an excellent framework in which to position multimedia technologies within the field of information science and technology. Individual contributions provide overviews of multimedia education, multimedia messaging, and multimedia databases while also exploring critical stumbling blocks of this field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of multimedia technologies.

Section 2. Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design and implementation of multimedia technologies. Throughout these contributions, research fundamentals in the discipline are presented and discussed. From broad examinations to specific discussions on electronic tools, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful multimedia interfaces, applications, and even environments are discussed.

Volume II

Section 3. Tools and Technologies

This section presents extensive coverage of the interaction between multimedia and the various tools and technologies that researchers, practitioners, and students alike can implement in their daily lives. These chapters provide an in-depth analysis of mobile multimedia, while also providing insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with countless examples of the tools that facilitate the transmission of multimedia data. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

Section 4. Utilization and Application

This section introduces and discusses a variety of the existing applications of multimedia technologies that have influenced education, science, and even music and proposes new ways in which multimedia technologies can be implemented within organizations and in society as a whole. Within these selections, particular multimedia applications, such as face recognition technology and educational, are explored and debated. Contributions included in this section provide excellent coverage of today's multimedia environment and insight into how multimedia technologies impact the fabric of our present-day global village.

Section 5. Organizational and Social Implications

This section includes a wide range of research pertaining to the social and organizational impact of multimedia technologies around the world. Chapters introducing this section analyze multimedia as a vehicle for cultural transmission and language, while later contributions offer an extensive analysis of educational multimedia. The inquiries and methods presented in this section offer insight into the integration of multimedia technologies in social and organizational settings while also emphasizing potential areas of study within the discipline.

Volume III

Section 6. Managerial Impact

This section presents contemporary coverage of the more formal implications of multimedia technologies, more specifically related to the corporate and managerial impact of the core concepts of multimedia, and how these concepts can be applied within organizations. The design and implementation of multimedia advertising is the focus of this section, which provides a how-to guide for multimedia business and commerce. The managerial research provided in this section allows executives and employees alike to understand the role of multimedia technology in business.

Section 7. Critical Issues

This section addresses conceptual and theoretical issues related to the field of multimedia technologies, which include quality of service issues in multimedia transmission and the numerous approaches adopted by researchers that aid in making multimedia technologies more effective. Within these chapters, the reader is presented with analysis of the most current and relevant conceptual inquires within this growing field of study. Particular chapters address methodologies for the organization of multimedia objects and the relationship between cognition and multimedia. Overall, contributions within this section ask unique, often theoretical questions related to the study of multimedia technologies and, more often than not, conclude that solutions are both numerous and contradictory.

Section 8. Emerging Trends

This section highlights research potential within the field of multimedia technologies while exploring uncharted areas of study for the advancement of the discipline. Introducing this section are selections addressing the need for universal access to multimedia. Additional selections discuss the future of multimedia education, advances in multimedia transmission on the Internet, and the possibilities and limitations of multimedia content protection. These contributions, which conclude this exhaustive, multi-volume set, provide emerging trends and suggestions for future research within this rapidly expanding discipline.

Preface

As multimedia technologies and their applications have witnessed explosive growth within the past two decades, information has become increasingly interactive and multidimensional. Traditional text-based data has been augmented and, in some cases, replaced by audiovisual content that is used to transform teaching styles, enhance business transactions, and promote cultural literacy. Researchers, students, and educators have benefited from and been challenged by increased access to multimedia data on the Internet, television, and even on their personal mobile devices. These technologies and their applications will continue to pervade and simplify our daily lives and, as a result, we must continue to understand, develop, and utilize the latest in multimedia research and exploration.

As the study of multimedia technologies and their applications has grown in both number and popularity, researchers and educators have devised a variety of techniques and methodologies to develop, deliver, and, at the same time, evaluate the effectiveness of their use. The explosion of methodologies in the field has created an abundance of new, state-of-the-art literature related to all aspects of this expanding discipline. This body of work allows researchers to learn about the fundamental theories, latest discoveries, and forthcoming trends in the field of multimedia technologies.

Constant technological and theoretical innovation challenges researchers to stay abreast of and continue to develop and deliver methodologies and techniques utilizing the discipline's latest advancements. In order to provide the most comprehensive, in-depth, and current coverage of all related topics and their applications, as well as to offer a single reference source on all conceptual, methodological, technical, and managerial issues in multimedia technology, Information Science Reference is pleased to offer a three-volume reference collection on this rapidly growing discipline. This collection aims to empower researchers, students, and practitioners by facilitating their comprehensive understanding of the most critical areas within this field of study.

This collection, entitled **Multimedia Technologies: Concepts, Methodologies, Tools, and Applications**, is organized into eight distinct sections which are as follows: 1) Fundamental Concepts and Theories, 2) Development and Design Methodologies, 3) Tools and Technologies, 4) Utilization and Application, 5) Organizational and Social Implications, 6) Managerial Impact, 7) Critical Issues, and 8) Emerging Trends. The following paragraphs provide a summary of what is covered in each section of this multi-volume reference collection.

Section One, **Fundamental Concepts and Theories**, serves as a foundation for this exhaustive reference tool by addressing crucial theories essential to understanding multimedia technologies. Opening this elemental section is "Fundamentals of Multimedia" by Palmer W. Agnew and Anne S. Kellerman, which defines the term "multimedia," provides an overview of end-user multimedia devices, and addresses some of the main issues and challenges within the field. Specific applications of multimedia technologies are discussed in selections such as "Core Principles of Educational Multimedia" by Geraldine Torrisi-Steele and "Introduction to Mobile Multimedia Communications" by Gour C. Karmakar, Laurence S.

Dooley, and Michael Mathew. Within the contribution "Multimedia Databases," researcher Mariana Hentea explains the fundamental use and importance of multimedia databases in shaping on-demand television, medical systems, and even fashion design. Similarly, in "Multimedia Information Retrieval at a Crossroad," Qing Li, Jun Yang, and Yueting Zhuang outline the main methods used for retrieving multimedia content and highlight both the current and emerging applications of such technology. The selections within this comprehensive, foundational section enable readers to learn from expert research on the elemental theories underscoring multimedia technologies.

Section Two, **Development and Design Methodologies**, contains in-depth coverage of conceptual architectures and frameworks, providing the reader with a comprehensive understanding of emerging theoretical and conceptual developments within the development and utilization of multimedia technologies. "Content-Based Multimedia Retrieval" by Chia-Hung Wei and Chang-Tsun Li suggests that content-based retrieval of multimedia content, as opposed to traditional text-based retrieval, makes database searching more efficient. Other selections, such as "Cognitively Informed Multimedia Interface Design" by Eshaa M. Alkhalifa, explain how cognitive psychology has helped to change the design of multimedia educational systems. The design of multimedia systems on mobile devices is explored at length in selections such as "Enabling Multimedia Applications in Memory-Limited Mobile Devices" by Raul Fernandes Herbster, Hyggo Almeida, Angelo Perkusich, and Marcos Morais; "Mobile Multimedia Collaborative Services" by Do Van Thanh, Ivar Jørstad, and Schahram Dustdar; and "Design of an Enhanced 3G-Based Mobile Healthcare System" by José Ruiz Mas, Eduardo Antonio Viruete Navarro, Carolina Hernández Ramos, Álvaro Alesanco Iglesias, Julián Fernández Navajas, Antonio Valdovinos Bardají, Robert S. H. Istepanian, and José García Moros. From basic designs to abstract development, chapters such as "Designing for Learning in Narrative Multimedia Environments" by Lisa Gjedde and "On a Design of SCORM-Compliant SMIL-Enabled Multimedia Streaming E-Learning System" by Sheng-Tun Li, Chu-Hung Lin, and Pao-Ta Yu serve to expand the reaches of development and design methodologies within the field of multimedia technologies.

Section Three, **Tools and Technologies**, presents extensive coverage of various tools and technologies and their use in creating and expanding the reaches of multimedia applications. The emergence of mobile devices and the potential for enabling multimedia content on these devices is the subject of articles such as "Multimedia for Mobile Devices" by Kevin Curran; "Multimedia Contents for Mobile Entertainment" by Hong Yan, Lara Wang, and Yang Ye; and "Multimedia Information Design for Mobile Devices" by Mohamed Ally. The new, multimedia-enabled face of distance education is explored throughout Hakikur Rahman's pair of contributions, "Interactive Multimedia Technologies for Distance Education Systems" and "Interactive Multimedia Technologies for Distance Education in Developing Countries." Throughout these selections, Rahman explains how multimedia technologies have transformed the physical classroom into the virtual classroom. Other technologies that are investigated within this section include digital watermarking, in the selections "Digital Watermarking for Multimedia Transaction Tracking" by Dan Yu and Farook Sattar and "Digital Watermarking Schemes for Multimedia Authentication" by Chang-Tsun Li, and communication systems on digital televisions, which are detailed in "Multimedia Communication Services on Digital TV Platforms" by Zbigniew Hulicki. These rigorously researched chapters provide readers with countless examples of the up-and-coming tools and technologies that emerge from or can be applied to the multidimensional field of multimedia technologies.

Section Four, **Utilization and Application**, explores the ways in which multimedia technologies and their applications have been practically employed in a variety of contexts. This collection of innovative research begins with "Integrated-Services Architecture for Internet Multimedia Applications" by Zhonghua Yang, Yanyan Yang, Yaolin Gu, and Robert Gay, which documents the emergence of multimedia applications on the Internet. As music retrieval has been an essential part of the multimedia revolution,

several selections, including "Interactive Multimedia MUSICNETWORK: An Introduction" by Kia Ng and Paolo Nesi and "Content-Based Music Summarization and Classification" by Changsheng Xu, Xi Shao, Namunu C. Maddage, Jesse S. Jin, and Qi Tian, document the classification and study of music-related multimedia technologies. Another application of multimedia technology, face recognition, is studied in "Face Recognition Technology: A Biometric Solution to Security Problems" by Sanjay K. Singh, Mayank Vatsa, Richa Singh, K. K. Shukla, and Lokesh R. Boregowda. As this section concludes, some of the more novel applications of multimedia technologies are surveyed. "Location-Based Multimedia Services for Tourists" by Panagiotis Kalliaras, Athanasios-Dimitrios Sotiriou, P. Papageorgiou, and S. Zoi presents a particular system that aims to provide its users with personalized, tourism-related multimedia information. From established applications to forthcoming innovations, contributions in this section provide excellent coverage of today's global community and demonstrate how multimedia technologies impact the social, economic, and political fabric of our present-day global village.

Section Five, **Organizational and Social Implications**, includes a wide range of research pertaining to the organizational and cultural implications of multimedia technologies. Introducing this section is "Multimedia as a Cross-Channel for Cultures and Languages" by Ramesh C. Sharma and Sanjaya Mishra, a selection that identifies multimedia's role in both preserving and transmitting culture. One of the most widely researched topics in multimedia research—the impact of multimedia technologies upon the modern-day educational system—is explored at length in chapters such as "Teaching, Learning and Multimedia" by Loreen Marie Butcher-Powell, "Planning for Multimedia Learning" by Patrick J. Fahy, and "Web-Based Synchronized Multimedia Lecturing" by Kuo-Yu Liu and Herng-Yow Chen. Other contributions, such as "Web-Based Multimedia Children's Art Cultivation" by Hao-Tung Lin and Herng-Yow Chen and "Student-Generated Multimedia" by Mathew Mitchell, explore the ways in which multimedia authoring among students has been an asset to their overall educational experience. Overall, the discussions presented in this section offer insight into the integration of multimedia technologies into society and the benefit these technologies have provided.

Section Six, **Managerial Impact**, presents contemporary coverage of the applications and implications of multimedia technologies in a business setting. Core concepts such as mobile commerce, Internet security, and the evolution of new advertising techniques are discussed in this collection. "Distanced Leadership and Multimedia" by Stacey L. Connaughton explains how multimedia has allowed virtual teams, who may never see each other face-to-face, communicate more effectively. "Short Message Service (SMS) as an Advertising Medium" by Shintaro Okazaki provides a summary of the use of both SMS and MMS for mobile advertising. Similarly, the selection "Mobile Multimedia for Commerce" by P.M. Melliar-Smith and L.E. Moser describes the rise of mobile commerce and explains that, since mobile devices are portable, they are the perfect tools for convenient selling and purchasing. Tziporah Stern's "Internet Privacy from the Individual and Business Perspectives" explains how online privacy has become a major issue for businesses and individuals alike. Within this selection, Stern provides both an overview of the problem and a list of potential solutions that individuals and businesses can adopt to make Web browsing and shopping more secure. The comprehensive research in this section offers an overview of the major issues that businesses must address in order to remain successful and current in an environment rich with multimedia content and interaction.

Section Seven, **Critical Issues**, presents readers with an in-depth analysis of the more theoretical and conceptual issues within this growing field of study by addressing topics such as quality of service (QoS) and multimedia security. "Distributed Approach for QoS Guarantee to Wireless Multimedia" by Kumar S. Chetan, P. Venkataram, and Ranapratap Sircar and "Quality of Service Issues in Mobile Multimedia Transmission" by Nalin Sharda discuss current and potential challenges in successfully transmitting multimedia content over wireless networks. Daniel J. Buehrer's "Organizing Multimedia

Objects by Using Class Algebra" highlights a particular method for retrieving Web-based multimedia content. Similarly, specific methods for image retrieval and indexing are presented and defined in selections such as "A Stochastic and Content-Based Image Retrieval Mechanism" by Mei-Ling Shyu, Shu-Ching Chen, and Chengcui Zhang and "A Spatial Relationship Method Supports Image Indexing and Similarity Retrieval" by Ying-Hong Wang. Concluding this collection of the more conceptual issues within the field is "Multimedia Security and Digital Rights Management Technology" by Eduardo Fernandez-Medina, Sabrina De Capitani di Vimercati, Ernesto Damiani, Mario Piattini, and Pierangela Samarati, in which the importance of defining who has the rights to particular multimedia content is addressed. In all, the theoretical and abstract issues presented and analyzed within this collection form the backbone of revolutionary research in multimedia technologies and their applications.

The concluding section of this authoritative reference tool, **Emerging Trends**, highlights research potential within the field of multimedia technologies while exploring uncharted areas of study for the advancement of the discipline. New IETF transport layer protocols in support of multimedia data transmission are presented and explored within Michael Welzl's "New Internet Protocols for Multimedia Transmission," while the potential for a multimedia world is debated within "Universal Multimedia Access" by Andrea Cavallaro. Later selections, such as "Toward Effective Use of Multimedia Technologies in Education" by Geraldine Torrisi-Steele, maintain that the current use of multimedia in education is problematic and present guidelines for the future construction of multimedia-informed educational systems. Similarly, in their contribution "Future Directions of Multimedia Technologies in E-Learning," researchers Timothy K. Shih, Qing Li, and Jason C. Hung argue for the incorporation of pedagogic theory into the design of distance learning systems which will, in their opinion, make learning more efficient. This final section demonstrates that multimedia technologies, with their infinite potential for application, will continue to both shape and define the way we access and absorb information.

Although the contents of this multi-volume book are organized within the preceding eight sections which offer a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. Furthermore, to ensure that the scholar, researcher, and educator have access to the entire contents of this multi-volume set, as well as additional coverage that could not be included in the print version of this publication, the publisher will provide unlimited, multi-user electronic access to the online aggregated database of this collection for the life of the edition, free of charge when a library purchases a print copy. In addition to providing content not included within the print version, this aggregated database is also continually updated to ensure that the most current research is available to those interested in multimedia technologies.

Within the past two decades, multimedia content began to occupy our computers, television screens, and mobile devices and has made the information age a reality. The applications of multimedia technology are both diverse and innumerable—education, business, and even art have been revolutionized by an easily accessible flood of interactive data. Research into how to properly access, distribute, and guarantee the security of multimedia content has implications in constructing multimedia interfaces, ensuring that mobile devices effectively transmit multimedia data, and shaping the future of commerce. With continued innovation in multimedia technologies and their applications and ongoing research into the best ways to distribute and utilize multimedia content, the discipline will continue to grow and transform as our world becomes more interactive.

The diverse and comprehensive coverage of multimedia technologies in this three-volume, authoritative publication will contribute to a better understanding of all topics, research, and discoveries in this developing, significant field of study. Furthermore, the contributions included in this multi-volume collection series will be instrumental in the expansion of the body of knowledge in this enormous field,

resulting in a greater understanding of the fundamentals while also fueling the research initiatives in emerging fields. We at Information Science Reference, along with the editor of this collection, hope that this multi-volume collection will become instrumental in the expansion of the discipline and will promote the continued growth of multimedia technologies.

Introductory Chapter
A Brief Introduction to the Field of Multimedia Technologies

Syed Mahbubur Rahman
Minnesota State University, Mankato, USA

INTRODUCTION

In an age where information rules, computer-based multimedia technology is a tool for communicators of all trades and is also an effective catalyst for change. Multimedia is a technology that allows us to present text, audio, images, animations, and video in an interactive way that has created a tremendous impact on all aspects of our day-to-day life. It also has the potential to continue to create ever more fascinating applications, some of which are described in articles listed in the references.

Technology is changing the world. However, the technology by itself can not change the world. It is the people who adopt and use the technology that make the changes. Accordingly, the inherent property of multimedia to support human-centered computing (HCC) may be credited for its explosive growth in all areas of application as is evident from several research works included in the references. Becvar has investigated how video blogging ("vlogging") systems affect the learning practices involved in training novice practitioners, and how integrating new technology alters the complex social dynamics of professional training (Becvar, 2007).

Present-day information access, which is a part of our everyday life, invariably involves multimedia data in some form or another. The use of multimedia enhances a user's ability to communicate and collaborate. A major component required in multimedia applications is a computer with high processing speed and large storage capacity. The hardware cost is decreasing at a rate never seen before, along with a rapid increase in the storage capacity, computing power, and network bandwidth. These developments have made use of multimedia more affordable and contributed to the tremendous growth in production and use of multimedia contents that we are experiencing recently. Multimedia technology has demonstrated the potential to evolve the paradigm of end-user computing, from interactive text and graphics model, into one more compatible with the digital electronic world of the 21st century. It is almost impossible to track the magnitude and breadth of the changes that multimedia and communication technology is undergoing.

This is an introductory chapter which aims to present basic terminology, tools, formats, and content protection used in multimedia applications and their development. It discusses basics of multimedia networking, security, issues, and trends. It also includes an extensive list of references on latest research issues and future trends on multimedia development and application areas.

WHAT IS MULTIMEDIA?

The word **multimedia**, originating from the Latin words "multum" and "medium", means combination of multiple media contents. It is a technology that, even today after two decades of explosive growth, means different things to different people. It might be an artistic medium or a communication tool or a teaching and learning tool for some, while it might be a way to complete a business transaction for others. In general, multimedia includes a combination of text, audio, still images, animation, video, and interactive content. The integration of multimedia technology into the communication environment has the potential to transform an audience from passive recipients of information to active participants in a media-rich learning process. The term "rich media" is synonymous for interactive multimedia. Currently multimedia is widely used as a computer-based interactive communications process that includes any combination of static (text, graphics, and still images, etc.) and active (sound, animation, and video, etc.) media. Inclusion of more than one media with at least one of them as active media is required to preserve the definition of multimedia. Most current day Web pages are examples of use of multimedia. Multimedia provides a real world feeling by incorporating a multi-sensory experience.

EVOLUTION OF MULTIMEDIA

Throughout the history of digital technologies, multimedia has always existed in one form or another. Not too long ago multimedia was defined as the combination of images with sound. A common implementation of early "multimedia" was refrigerator-size kiosks containing both a monitor and laserdisc player hooked up to a push-to-start button. The multimedia presentations were linear in early days. The users were presented with information to listen or read or do both as passive witness without any form of interaction, except to push the start button. In other early implementations of multimedia, for example, a narrator would tell a story with a series of still pictures or even videos filling the screen. There were no ways a viewer could randomly access the specific sections of the presentation which were more important or useful and skip the boring parts. Users were not very impressed with this form of technology and were looking for innovative approaches. With technological development, interactivity has been introduced with videos being played from a laserdisc controlled by some computer that make use of the random-access capability of the laserdisc player and allow a viewer to select random modules of content. This capability empowered the users to control the path and flow of content, while bypassing superfluous topics. With hyperlink and hypermedia interface a user can navigate through into the subject areas of his/her interest.

As new developments are taking place, the multimedia technology is supported with increased hard disk capacity, higher data bandwidth, new video compression technologies, more sophisticated multimedia software, and CD/DVD included as a common feature of computers. Within a short span of time, personal computers proved to be an appropriate medium to deliver full screen, full motion video with their innovative technologies and video compression technologies. Apple computer was one of the early computers coupled with these multimedia features.

The definition of multimedia has now been restructured—a mix of elements of hyperlinked text, animation, graphics, video, and audio, in an interactive environment. This technology is constantly changing and evolving as new product versions arrive each day replacing the older ones that has resulted a competition for high-tech corporations in which only the fittest and the best can survive.

A good multimedia application is one that keeps the technology invisible from the user. The purpose of a good multimedia presentation is to envelope the viewer with rich text, clear sound, sharp image, and smooth motion that can be stopped, started, and cross-referenced with ease.

CATEGORIES OF MULTIMEDIA

Multimedia may be divided into following three categories based on their functions and how they are organized.

- Linear and non-linear;
- Interactive and non-interactive; and
- Real-time and recorded.

Linear active content progresses without any navigation control for the viewer such as a cinema presentation. *Non-linear* content offers user interactivity to control progress as used with a computer game or used in self-paced computer-based training.

Interactive multimedia is the means to interface with different media through input (e.g., a computer keyboard, mouse, touch screen, on screen buttons, and text entry, etc.) and output devices allowing a user to make decisions as to what takes place next with multimedia.

Multimedia presentations can be *live* (real-time) or *recorded*. A recorded presentation may allow interactivity via a navigation system. A live multimedia presentation may allow interactivity via interaction with the presenter or performer. More details are available in the reference section.

MULTIMEDIA FILE FORMATS

Multimedia formats represent the various ways each media type is stored and used to transport multimedia data. This section covers a range of multimedia file formats—especially audio, video, and image file formats—used in the delivery of multimedia and includes both formal standards and de facto standards. Media formats may differ for the purpose it is used, for example, for streaming or for downloading.

Formats suitable for *streaming* should be able to transfer data in a continuous stream (usually for audio or video), for example, over the Internet, so that the player can play it as the data arrives without waiting for the entire file to be downloaded. At start the streaming media players store several seconds worth of data, known as a buffer, in its memory. The player then begins playback of the file from the buffer, while the data continues to fill in. The buffer, as the name suggests, allows for continuous playback of the audio or video by compensating for any delays in the transmission of the rest of the file. The buffer absorbs the bursts of data as they are received and releases it at a constant bit rate for smooth playback. For *downloading* purpose, the file format does not need to satisfy this criterion of transferring data continuously.

There are several formats for each media with different features requiring the players to be capable of decoding these features. Fortunately many hardware and software players are now available, which are able to support common multiple formats. There are also tools available for converting a media in one format to different formats (Pereira, 2007; Viljoen, Calitz, & Cowley, 2003).

Audio Formats: There are a number of different *types* of audio file formats. The most common are wave files (wav), MPEG Layer-3 files (mp3) and AIFF (Audio Interchange File Format) file types. Common streaming audio formats include Windows Media Audio/Active Streaming Format (ASF), QuickTime, RealAudio, and MP3. There are, however, some other audio file types included in the Table 1. The format types are also represented by the file extension. Codec determines the way the audio is compressed and stored. Some file types always use a particular codec, while others may support multiple codecs.

Initial internet browsers, such as Netscape Navigator and Mosaic, included AU (Audio, or m-law), WAV (Waveform Audio), and AIFF (Audio Interchange File Format) formats and got widespread Internet acceptance. These formats are considered as better choices for inclusion on web pages because of their cross-platform support, and their ability to run natively within a browser. Both WAV and AIFF are commonly used on the Web at lower-quality sampling rates to keep file size reasonable and reduce upload and download time.

Most of the streaming multimedia formats are proprietary and require special servers for encoding and transmission. Some commonly used streaming audio formats are RealAudio, XingMPEG, and streaming audio for the popular Shockwave plug-in. XingMPEG and Shockwave each have compression ratio of up to 26:1 and 176:1, respectively. For both these formats the average file size varies depending on the strength of compression. The two streaming formats, MPEG (Moving Pictures Expert Group) and RealAudio have changed audio on the Internet. MPEG is best known as a standard for the compression of video files claiming very high compression ratios as high as 26:1. However, ratios greater than 12:1 are seldom used due to the sacrifices in quality. Even at this compression ratio MPEG is capable of delivering CD-quality audio files that in any other format is extremely difficult to achieve. RealAudio has also demonstrated itself to be one of the fastest growing proprietary streaming formats. RealAudio Player allows users to download both on-demand and live-broadcast streaming audio files. The RealAudio file

Table 1. Common digital audio formats

Audio Formats	Extensions	Codec	Characteristics
AU (Sun/Next)	.au	*u-law	- Relatively good compression and small file size (2:1 and 8 Kb/sec). - 8 bit encoding only; sound acceptable, but not premium quality. - introduced by Sun Microsystems and NeXT Compute.
WAV	.wav	*PCM	- 16 bit, better sound quality than AU. - 1 minute audio consume more than 10MB. - Native support in windows. - No compression and big file size (10 Mb/s). - Higher quality than AU.
AIFF (Mac)	.aif, .aiff	*PCM	- WAV comparable sound quality. - 8 or 16 bit sampling. - Native support on Mac. - Small file size with 8 bit sampling.
MPEG audio	.mp2 .aac	MPEG Audio	- Good sound quality. - Sometimes proprietary nature makes them incompatible.
MP3	.mp3	MPEG Audio Layer-III	- compressed to 10:1 of an equivalent PCM. - most recommended for music.
Windows Media Audio	.wma	Proprietary (Microsoft)	- Designed with Digital Rights Management (DRM) abilities for copy protection.
QuickTime	.qt	Proprietary (Apple Computer)	- supports both streaming audio and streaming video. - widely used for streaming video on the Web.
RealAudio	.ra, ram	Proprietary (Real Networks)	- supports both streaming audio and streaming video.

** Can be used with other codecs*

format supports two levels of compression: an "AM sound" quality for 14.4-Kbps modems and an "FM sound" quality for 28.8-Kbps and faster connections. However, audio often "gaps out" on 14.4-28.8 modem connections. Depending on the algorithm used, RealAudio files typically require only 1.1 to 2.4 kilobytes per second or between 3.6 MB and 8 MB per hour of audio. MetaVoice (VOX) format is a good choice for delivering speech.

Video Formats: Some common video formats are AVI (Audio Video Interleave), MPEG (Moving Picture Expert Group), and QuickTime (MOV). A breakdown of these formats is shown in Table 2.

Because movies involve both audio and video, the file sizes as a rule are very large. QuickTime supports compression ratios as high as 50:1, yet a typical MOV file consumes almost 70 KB per second of video, or about 4 MB per minute. MPEG compression ratios can be as big as 200:1. Accordingly, MPEG video files are usually smaller than QuickTime movies. Because of these advantages, MPEG format is a viable alternative for inclusion of video in internet based applications. AVI's widespread acceptance is due to native support by the Windows Media Player application.

Some common streaming video formats include XingMPEG video and VDOnet (VDO) file types. There are codecs available that enable WAV, MPEG, QT, and standard AVI streaming. Due to the large amount of data transfer that video demands, only those users connecting at T1 speeds may be able to properly view a full-motion video. VDO uses a "wavelet" method to compress AVI files into its proprietary format. Although compression ratios vary, VDO files average about 1 MB per minute of video.

H.264: H.264/Advanced Video Coding (AVC) is a new video compression standard developed jointly by the Joint Video Team of ITU-T Q.6/SG16 VCEG and ISO/IEC MPEG. The partnership effort is also known as Joint Video Team (JVT). The final drafting work on the first version of the standard was completed in May 2003. This relatively new standard has already gained wide industry acceptance and is being adopted in many regional and industry-specific standards because of its high compression efficiency when compared to similar schemes such as H.262/MPEG-2. So it deserves more detailed discussion compared to the other standards.

This standard is known by different names, such as, H.264/AVC or AVC/H.264 or H.264/MPEG-4 AVC or MPEG-4/H.264 AVC. H.264 is a name related to the ITU-T line of H.26x video standards. AVC relates to the ISO/IEC MPEG side of the partnership project. H.264 is also referred to as "MPEG-4 Part 10" (part of the MPEG-4 specification, formally, ISO/IEC 14496-10). The ITU-T H.264 standard and the ISO/IEC MPEG-4 Part 10 standard are jointly maintained so that they have identical technical content.

The H.264/AVC standard provides much better video quality (reduction in artifacts such as blockiness, color bands, etc.) at substantially lower bit rates, higher resolution and with lower storage requirements compared to the previous compression schemes. It also allows flexibility to be applied to a very wide variety of applications (e.g., for both low and high bit rates, and low and high resolution video) and work well on wide variety of networks and systems (e.g., for broadcast, DVD storage, RTP/IP packet networks, and ITU-T multimedia telephony systems).

H.264 is becoming the worldwide digital video standard for consumer electronics and personal computers. H.264 has been adopted by the Motion Picture Experts Group (MPEG) to be a key video compression scheme in the MPEG-4 format for digital media exchange. Following are some important applications where the standard has been adopted.

- Broadcast over cable, satellite, cable modem, DSL, terrestrial, and so forth. Examples include:
  - Broadcast television in Europe (approved by the Digital Video Broadcast (DVB) standards body in Europe in late 2004).
  - Receivers of HDTV and pay TV channels for digital terrestrial broadcast television services (referred to as "TNT") in France in late 2004.

Table 2. Common video formats

Video Formats	Characteristics
AVI (Audio Video Interleave)	• Uncompressed results high quality video, but large files. • Often there is problem synchronizing audio with video. • The entire file must be downloaded before being played. • Native support on Windows. • Average AVI file size is between a MOV file size and MPEG file size.
MPEG (Motion Pictures Experts Group)	• Can provide VHS or better quality movies. • Up to 200:1 compression ratio and storage rate is 2.8MB/minute. • Can produce full-motion video with relatively small file size. • Typically MPEG1 is used to make a one hour VCD movie. • MPEG1 quality is same as VHS. • MPEG2 quality is better than VHS and used to make DVD video, can be used to make about a 30 minute high quality VCD.
MPEG - 4	• ISO/IEC standard developed in 1998 by MPEG. • Includes many features of MPEG-1 and MPEG-2 and other related standards. • New features include extended VRML support for 3D rendering, object-oriented composite files (including audio, video and VRML objects). • Multiplexes and synchronizes data, associated with media objects, in such a way that they could be transported further via network channels. • Developed primarily for low bit-rate video communications and later its scope was expanded to be much more of a multimedia coding standard. • Enables developers to control their content better and to fight more effectively against copyright violations. • MPEG-4 part 10 (MPEG-4 AVC/H.264) is becoming a more accepted standard. (H.264 is discussed below as a separate section).
MOV (Apple QuickTime Movie)	• Requires Apples QuickTime Movie Player. • Runs natively on the Mac platform. • Up to 50:1 compression ratio and storage rate is 4 MB/minute. • Relatively large file size. • Depending on Compression chosen it can provide a very high quality video clip. However, better quality video requires more storage space. • Can be streamed across the Internet and viewed before entire file has been downloaded using a QuickTime streaming server.
ASF (Advanced Systems Format) WMV (Windows Media Video)	• Can be streamed across the Internet and viewed before entire file has been downloaded when using a Windows Media server. • Audio and/or Video content can be compressed with a wide variety of codecs. • An extensible file format designed to store synchronized multimedia data. • Requires Windows Media Player be installed on client.
RM (Real Media)	• Can be streamed across the Internet and viewed before entire file has been downloaded when using a Real Networks Streaming server. • Has very high compression, but at a cost to quality. • Requires Real Networks RealPlayer to view content.

- The Digital Multimedia Broadcast (DMB) service in the Republic of Korea.
- Mobile-segment terrestrial broadcast services of ISDB-T in Japan.
- Major broadcasters in Japan including NHK, Tokyo Broadcasting System (TBS), Nippon Television (NTV), TV Asahi, Fuji Television, TV Tokyo.
- Direct broadcast satellite TV services such as DirecTV, Dish Network in U.S.; Euro1080 in Europe; Premiere, ProSieben HD & Sat1 HD in Germany; BSkyB in the United Kingdom and Ireland, etc.

- Interactive or serial storage on optical and magnetic devices, DVD, etc. For example, it has been selected as a key compression scheme (codec) for the next generation of optical disc formats, HD-DVD format of DVD forum and Blu-ray disc (sometimes referred to as BD or BD-ROM) format of the Blu-ray Disc Association.
- Conversational services over ISDN, Ethernet, LAN, DSL, wireless and mobile networks, modems, etc., or mixtures of these.
- Video-on-demand or multimedia streaming services over ISDN, cable modem, DSL, LAN, wireless networks, etc.
- Multimedia messaging services (MMS) over ISDN, DSL, Ethernet, LAN, wireless and mobile networks, etc.
- Quick Time, Flash Player, YouTube
- In most application areas of the Motion Imagery Standards Board (MISB) of the United States Department of Defense (DoD).
- For international military use by the North Atlantic Treaty Organization (NATO).

Several companies are producing custom chips capable of decoding H.264/AVC video, will allow widespread deployment of low-cost devices capable of playing H.264/AVC video at standard-definition and high-definition television resolutions. More details can be found at http://en.wikipedia.org/wiki/H.264.

Image File Format: Most common image file formats include Joint Photographic Experts Group (JPEG - .jpg), PDF (use Type I postscript fonts - .pdf), GIF (.gif), TIFF, and so forth. Table 3 illustrates some commonly used file formats and their major features.

MULTIMEDIA TOOLS

Multimedia tools include hardware and software used in the process of developing multimedia applications, for delivering multimedia products and for later maintenance and modifications/update of the products. Most commonly used multimedia hardware includes video, sound cards, player, and recording devices. The hardware devices are going through dramatic improvements almost on a daily basis in their features and ease of use. Multimedia software development tools may be divided according to nature of their use as described below.

1. *Classification of multimedia tools based on their use in different phases of applications development*.
   - *Analysis Tools*: These tools help the designer to study existing system (if any) to identify strength, weaknesses, and opportunities for improvement and analyze the needs and goals for the project scope.

Table 3. Common image file format

Image File formats	Major Features
BMP	- 24 bit or 16.7 million colors (RGB). - 8-bit palette, or 256 colors (RLE), reduces the file size to about 10:1 ratio compared to BMP-RGB.
GIF	- 8-bit palette or 256 colors. - Supports animation and is still widely used to provide image animation effects.
JPEG	- Developed in 1991. In most cases lossy format. - 24-bit total for red, green, and blue. Produces relatively small file sizes. - Min. compression about 5:1 ratio may be achieved compared to BMP-RGB. - Min. progressive compression about 7:1 ratio may be achieved. - Max. compression about 50:1 ratio may be achieved compared to BMP-RGB. - Max. progressive compression about 70:1 ratio may be achieved. - JPG quality is not preferred for archiving master copies.
JPEG-2000	- Developed to achieve a better image quality in a smaller file. - The standardized filename extension is .jp2 for ISO/IEC 15444-1 conforming files and .jpx for ISO/IEC 15444-2 files. The MIME type is image/jp2. - JPEG 2000 uses wavelet based compression, whereas JPEG used the DCT compression. - JPEG 2000 is not widely supported in web browsers.
PCX	- 24 bit or 16.7 million colors.
TIFF Tagged Image File Format	- image format that normally saves 8, 16, 24 or 48 bits per color. - Gray scale – 8 or 16 bit. - Line Art (bi-level) - 1 bit. - Can be lossy or lossless; provide relatively lossless compression. - Widely used as printing industry photograph standard. - Simple and widely used for good quality archived master.
TIFF-LZW compression	- Internally used in Windows. - Not compressed.
RAW	- Not standardized. - Lossless or nearly lossless compression. - Smaller file size than TIFF.
PNG (Portable Network Graphics)	- RGB - 24 or 48 bits, Grayscale - 8 or 16 bits, Indexed color - 1 to 8 bits, Line Art (bi-level) - 1 bit. - Compress files at a similar ratio to jpeg. Unlike jpeg, resaving an image will not degrade its quality. - Used for good quality archive or master.

- *Design Tools*: The design tools are useful for planning the project development, including user characteristics and specific objectives.
- *Management Tools*: These tools are used for the management of the multimedia development process as a whole.
- *Production Tools*: These tools are helpful in the actual production of the multimedia product.
- *Evaluation Tools*: These tools support the task of generating evaluations by various different means.

2. *Classification of multimedia tools based on the media type for which a software tool is used*.
   - Audio software
   - Graphic software
   - Video software
3. *Classification of multimedia tools based on the function of tool*. Multimedia software tools encompass a wide variety of software that a developer needs to use for different functionalities, for example, capturing, playing, combining images, text, music and sound, animation, video, and other special effects. Following are some software tools based on their functions belonging to each of these media categories (i.e., audio, video, text and graphics)
   - Media editors
   - Media viewers
   - Media recorders
   - Media format converters (e.g. bmp to jpeg)
   - Media converters (e.g. text to speech or speech to text converter etc.)
   - Media capture
   - Animators
   - Movie joiner and splitter
   - Watermarking tool
   - Multimedia for the Web
   - Business presentation tool
   - Screen saver creation
   - Slide show software
   - Multimedia photo albums
   - Multimedia authoring

There are several software tools available that are capable of providing the above functionalities separately and for each different media. However, the most commonly used tools have one or several built in functionalities to support several formats and media. For example, Windows media player plays both audio and video in several formats, such as ASF, Real Video/Real Audio 4.0, MPEG 1, MPEG 2, WAV, AVI, MIDI, MOV, VOD, AU, MP3, and QuickTime files etc. CoolEdit can edit, mix and add sound affect in a variety of audio file formats. Avid SoftImage, Animated Gif building packages such as *GifBuilder* can create and support animation; *animated greetings software* allows the user to create personalized

Table 4. Image/graphics/video editing tools

Tool Name	Major Features
Adobe Photoshop	• Allows layers of images, graphics and text • Includes many graphics drawing and painting tools • Sophisticate lighting effects filter • A good graphics, image processing and manipulation tool
Adobe Premiere	• Provides large number (up to 99) of video and audio tracks, superimpositions and virtual clips • Supports various transitions, filters and motions for clips • A reasonable desktop video editing tool
Macromedia Freehand	• Graphics drawing editing package

Table 5. Examples of additional multimedia tools

Name	Author	Type	First public release date	Operating System	Some Features	Protocols supported	Important formats
iTunes	Apple Inc.	Audio, video	2001	Win, Mac	Vp, os, md, vz	HTTP RTSP Podcasting	Mpeg-1, 2, 4, Flash, wmv, Asf, quicktime
QuickTime	Apple Computer	Audio, video	1991	Win, Mac	Vp, os, md, vz	HTTP RTSP Podcasting	Mpeg-1, 2, 4, flash, Mp3, wma, avi, quicktime, mp4
RealPlayer	RealNetworks	Audio, video	1995	Win, Mac, Linux, other unix, Solaris	Vp, md, vz	HTTP RTSP MMS Podcasting	Mpeg-1, 2, mpeg-4, flash, MP3, WMA, RealAudio Vorbis, avi, asf, quicktime, mp4
Windows Media Player	Microsoft	Audio, video	1992	Win, mac, win mobile	Vp, os, md, vz	HTTP RTSP MMS Podcasting	Most formats
Media Player Classic	Gabest	Audio, video	2003	win	vp	HTTP MMS	Mp3, wma, avi, asf, quicktime, mp4

electronic greetings with text, images, and audio files of different formats according to user's preferences. Table 4 and 5 contains some major features of few well known image/graphics/video tools.

Many other software with similar functionalities is also available commercially and also in the public domain.

Multimedia Authoring: Multimedia authoring tools are by far the most versatile and have lots of interactive controls for the user to develop complete multimedia applications from simple (e.g., slide show presentation) to most complex ones (e.g., computer games or interactive computer aided learning applications). Most authoring tools support WYSIWYG (*what you see is what you get*) environment or in a timeline-based environment. Programming and scripting languages are also supported for designing customized and advanced scenes. Other important feature includes exporting the developed projects to self-executing and self-installing files to a CD or DVD recording media. Some well known authoring tools available are Macromedia Director, Authorware, Flash, Hypercard, Hyper studio and IconAuthor etc. Important features of some authoring tools are documented in Table 6.

There are literally thousands of uses for this type of software, for example, computer-based training, surveys, quizzes and tests, encyclopedias, games, interactive kiosks, interactive presentations, screen savers, CD-ROM/DVD content creation, and advertisements, and so forth (Miguel, Barracel, & Panyella, 2004; Petridis, Saathoff, & Dasiopoulou, 2006).

Delivery of Multimedia Products: To make the multimedia products ready for distribution, most of the software tools have some capability of exporting the developed projects to self-executing, self-installing files. These categories of products have the capability to export contents as screen savers. An important feature to note about export specification is its ability to create cross-platform compatibility, create stand-alone files for a specific platform and/or for Web applications. Most animated greetings software creates self-executable files or Web publishable files.

Table 6. Authoring tools

Authoring Tool	Major Features
Macromedia Director	• A multimedia developing tool for any platform: CD's, DVD's, kiosks and of course, the Web. • Proven authoring tool for creating powerful games, simulations and multimedia applications. • Intuitive design and object-oriented development environment. • Authoring tool for creating powerful games, simulations and multimedia applications. • Support JavaScript, Flash(TM) MX 2004 content, DVD-Video, and the ability to create projector files for both Mac and Windows platforms in one simple step. • Full support for ECMAScript-compliant JavaScript syntax, which supplements traditional Lingo support. • Director's powerful features include two scripting languages, cross-platform publishing, and Flash integration. • combines broad support for media types, ease of use, bit-mapped graphics, true 3D rendering, high-performance, and an infinitely extendible development environment to deliver games, rich content and applications for the Internet, desktop, CDs and DVDs. • Lingo script language with own debugger allows more control including external devices, e.g., VCRs and video disk players. • Movie metaphor (the cast includes bitmapped sprites, scripts, music, sounds, and palettes, etc.). Ready for building more interactivities (buttons, etc.). • Inclusion of Lingo, its object-based scripting language, has made it the animation-capable program. The AfterBurner compression Xtra creates Shockwave files, allowing Web playback.
Authorware	• Professional multimedia authoring tool. • Authorware uses the same JavaScript engine found in Macromedia Dreamweaver MX. • All properties within Authorware can now be scripted making it easier for advanced developers to create commands, Knowledge Objects, and extensible content. • Create dynamic, data-driven applications by importing or exporting web-standard XML files into other applications. • Generate tab navigation and captions, and turn text into speech to comply with accessible software legislation. • Supports interactive applications with hyperlinks, drag-and-drop controls, and integrated animation. • Compatibility between files produced from PC version and MAC version.
Flash	• Developed by: Macromedia. • Platforms: Mac, Windows95, NT, WWW (via Flash Player). • A cast/score/scripting tool. • Primarily uses vector graphics. • Can create vector graphics from imported bitmaps. • Create engaging rich-media advertisements: including webmercials, interstitials, and banners. • XML transfer and HTML text support. • ActionScript development tools. • Produce standalone run-time animation applications.

DEVELOPMENT OF MULTIMEDIA APPLICATIONS

In the process of developing multimedia applications, there are some issues that need to be considered, some of which are listed in the following:

- The target audience
- The objective(s) of the application
- The structure of the application

- Multimedia building blocks used to present the proposed content
- The desired degree of interactivity between the user and the computer
- The expected level of user response

Development Steps: The development process for a multimedia title may be divided into several steps as below.

- *Project Planning*: In this step the development team presents a series of main ideas, facts, or short descriptions. Team decides on the project duration, milestones, and finance.
- *Project Design*: This is a step where the team discusses exactly what the application is going to do and how the interface has to be. Decides on the type of project and degree of non-linearity, interactivity. The presentation may be a series of charts and interfaces as detailed below and are very important in the design process of developing a multimedia project. These ideas and design concepts are used in the proposal or for presentation to a client and also in the production process.

    - Flow Chart shows the information flow of the project in the form of a diagram that should include all menus and submenus, introductory and information screens with text, image, audio and video contents. Charts contain boxes that indicate the various sections, which are connected by lines and arrows to indicate links, hierarchy and flow. Flow indicated by arrows can go from top down, or from left to right. The designed charts are expected go through various stages of modifications. Graphics program such as Photoshop or Illustrator may be used to create the chart.
    - Interface Sketches contain the detailed of each menu showing design concept, placement of titles, typographical styles, order/hierarchy of buttons, return arrows, interactivity, borders, image, graphics, video, and so forth.

- *Story Boarding*: For video material, including interviews, documentary, narrative pieces, and so forth, create a simple storyboard(s) that outlines the sequence of events, dialogue, texts, locations, camera shots, sound, music, and so forth. This provides a rough guide for shooting and editing, and need to be updated during the production process. A blueprint of the application is decided upon and created, including the navigation diagram to move from a story to a different story. Choice of media types plays an important role in deciding the acceptability of the final project.
- *Script Development*: This is where the content of the application is developed that would include narrations and images.
- *Production*: The backgrounds, scenes, transitions, animations and other presentation details are done.
- *Authoring*: In this step the developer puts together everything and gives it the form outlined during the project design stage.

A well-designed multimedia project must have a flow with a feeling of continuity that must draw interest and attention of the user. The following are some other considerations that need to be addressed during development of a successful multimedia project.

- The product should have a title or description.
- Graphics, images, and video are placed in the content ergonomically appropriate to the theme of the project and used only to enhance the intended information.

- Careful considerations must be given in the use of correct colors, video, animation, music, and sound effects to add powerful effects in the project design and make it successful.
- Visual message (image and video) should be used when it is clearer than text alone and when it demonstrates a procedure, process, or role-playing technique that is not well presented with text.
- Videos included should be short. Instead of showing a long video all at once, split it up with text, audio, or questions in between. Make sure that the video adds content to the theme.
- The text content need to be accurate, well written, complete with proper grammar and punctuation.
- The success of a large-scale multimedia project depends on a collective effort made by a team of talented communication and production experts—writers, designers, producers, audio and video technicians, systems engineers, and programmers (Kaskalis, Tzidamis, Margaritis, & Evangelidis, 2006; Miguel, Barracel, & Panyella, 2004; Petridis, Simou, & Dasiopoulou, 2006).

MULTIMEDIA COPYRIGHT PROTECTION

Piracy and other copyright violations regarding digital multimedia content represent a significant problem for legal content owners and content distributors. Preventing illegal content copying and distribution is a very difficult problem to solve. So, the digital rights management (DRM) for multimedia, that is, the protection of intellectual property rights for multimedia content, is an important area of interest.

Two methods, *steganography and cryptography*, are well known for copyright protection.

Steganography is the science of hiding information in such a way that only the owner and the intended recipient knows about the message. Others cannot see any change in the information content and can not even realize that there is a hidden message/owner's identity.

Due to the nature of human vision and hearing on one hand and typical highly redundant properties of multimedia documents on the other hand, a small noise can be inserted into an image, audio and video documents without any visible deterioration of the quality of audio, image, or video. A simple example of hiding data within an image file may be to include data by a method known as least significant bit (LSB) insertion. In this method, the binary representation of the hidden data is written in the image by modifying the LSB of each byte representing the color of each pixel of the image. Due to this modification of a bit in a pixel, the amount of visible change in the image is minimal and indiscernible to the human eye. A digital watermark aims to accomplish a similar function. For example, an image may have an embedded hidden signature so that the owner can later prove his/her ownership in case others attempt to portray the image as their own.

There are many other techniques for watermark insertion. Watermarks may be implanted into insignificant parts of the document (for instance in images this could be on the boundaries). This is certainly a good solution if the quality of the document is important. The drawback of this technique is that such watermarks can be easily removed. Robust watermarks therefore must be put into significant portion of data. A majority of multimedia watermarking schemes is based on frequency domain manipulation of the multimedia content. Robust watermark aims to modify significant frequency components making the changes difficult to be removed, but at the same time the changes should not visibly degrade the content of the media. Common goals of watermarking are as follows.

- The watermark is invisible and its presence should not be perceptible. This is comparatively easier to achieve due to the redundancy in the multimedia data and the tolerant nature of human vision and hearing.

- The watermarks should be difficult to remove.
- The watermarks should identify the owner of the document.

The second goal, which also implies in itself the third goal, are relatively difficult to assert due to a variety of signal processing tools, such as digital to analog (D/A), analog to digital (A/D), frequency transformation, filtering, equalization, and so forth, are accessible to an attacker. For an image, geometric distortions such as rotation, scaling and cropping, and so forth, may be applied to change the watermarks without noticeable degradation in the image.

In contrast, ***cryptography*** obscures the meaning of a message in such a way that the content becomes unintelligible and meaningless. Cryptography relies on the assumption that the protection is controlled by a secret key whose value is not known to attackers. Cryptography works as long as the attacker does not know the secret key. It is evident that it is not so easy to know some others' secret key. Another advantage of cryptography over steganography is that in case of a successful attack, the security can be easily restored simply by replacing the compromised key with a new one. This is not applicable to steganography as a new hiding scheme must be invented which replaces the compromised one.

Most *digital rights management* solutions make use of encryption in conjunction with digital watermarking techniques so that the information is double protected and ensure better security against illegal copying and distribution. Cryptographic techniques have the capability to provide the standard services (such as confidentiality, authentication, data integrity, and non-repudiation) of network security. In general, encryption techniques are used to prevent illegal copying and distribution, while digital watermarking techniques can be used to establish ownership and discourage copying by allowing grounds for legal actions. Well-designed robust watermarks should be difficult to remove. In case of audio and video files, any intentional or accidental attempts to remove watermarks will result in significant deterioration of the quality of audio and video. A robust watermarking cannot be removed even by repetition of lossy compression (such as JPEG), digital/analog (D/A), and analog/digital (A/D) conversions or any standard signal processing tools such as Fourier transform.

Watermarking the master copy does not prevent production of several identical copies. It also does not control distribution and in case of illegal distribution, trace its source. However, to control illegal copying and prevent the existence of multiple identical copies, it is necessary to have each copy with a unique watermark. So, in this case, existence of multiple copies of the same document indicates a forgery.

There is no ideal watermarking scheme. Consider a scheme based on digital signature. Clearly, attackers are unable to produce a new document with an appropriately modified watermark. However, it is not very difficult to distort the watermark of the document to such a degree that the rightful owner of the document may not be able to claim the ownership.

There are several research works to improve capability of multimedia copyright protection as listed in the references. The future efforts are likely to concentrate on development of new relatively inexpensive hiding techniques (steganography) to be used on massive scale for watermarking of images, video, and sound. Other future work can include extending the protection scheme to support parental rating of the content, variable number of allowed utilizations, time limitations for the content utilization, and similar controlling mechanisms. Interesting ideas of content protection based on biometric data were recently proposed. The methods rely on biometric data of the user and a layered encryption mechanism to achieve confidentiality of the multimedia content (Socek, Sramka, Marques, Oge, & C´ulibrk, 2006).

MULTIMEDIA NETWORKING

Multimedia networks, as the name indicates, are combinations of two basic technologies—networking and multimedia computing. It is a system consisting of connected nodes made to share multimedia data, hardware, and software. Multimedia networking started placing continuous demand on the network infrastructure, and was at odds with packet switching and LAN technologies. One major problem in implementing multimedia applications over TCP/IP has been the problem of delay and jitter. Most applications, which are real-time, cannot tolerate delay with large variations. It makes them unacceptable to the user, because of their unpredictable nature. The major problem arises because of absence of any bandwidth allocation protocols in IP or not setting up any connection to allocate a specific path in UDP. The Internet Engineering Task Force developed Resource Reservation Protocol (RSVP) is an effort to overcome this problem. RSVP over IP allows setup of resource reservations on behalf of an application data stream. RSVP essentially allows a router-based network to simulate circuit-switched network on a best effort basis. When an application requests specific quality of service (QoS) for its data stream, RSVP delivers the request to each router and host states to support the requested level of service. The improved performance and pervasiveness of TCP/IP networks has enabled users to share multimedia information more efficiently across local area and wide area networks, in particular over the Internet.

Lately, asynchronous transfer mode (ATM) has been developed to accommodate the real-time multimedia application issues, specially the delay and jitter problems. By using a 53-byte standard cell size to carry voice, data and video signals the delay problems can be avoided. It can also switch data via hardware, which is more efficient and less expensive. Different traffic types have been defined in ATM each delivering different QoS. One of the traffic types, known as constant bit rate (CBR) is most suitable for multimedia applications. CBR supplies a fixed bandwidth virtual circuit that takes care of delay-sensitive multimedia applications which could be containing real-time video and voice. ATM also provides low latency, high throughput, and scalability which make it a network of choice for supporting new high bandwidth multimedia applications as well as LAN and TCP/IP traffic. ATM speeds are scalable and can exceed 2.5GBPS over fiber.

Cisco, a dominant supplier of data networking hardware for LANs and WANs, offers multimedia software. The aim is to provide all the elements of an end-to-end infrastructure for voice, video, and data traffic across private and public networks.

Corporate Information Superhighway (COINS): Though with the advent of Internet the usage of multimedia applications has reached more people, overcoming the bandwidth limitations still remains a challenge for sometime to come. COINS is a globally connected, fast, efficient, cost-effective, high capacity multimedia network which supports multimedia applications. It is based on a fiber-optic backbone with a capacity of up to 10 gigabits per second to transmit voice, video, data, and images. COINS offer seamless inter-networking, vertical integration, electronic home banking, and electronic commerce. It also provides security, reliability, and is extremely cost-effective. The quest for building an information superhighway, that is, setting up high capacity telecommunications network that would carry vast amounts of digital binary data, is still on.

Multimedia Wireless Networking: For all existing applications, emerging wireless systems will bring a new generation of wireless multimedia applications. The NEC Corporation developed one of the early wireless transmission technologies based on the IEEE1394 high-speed serial bus and capable of 400 megabits, at transmission ranges up to 7 meters through interior wall and up to 12 meters by line-of-sight, which brought multimedia home networking another step closer to reality. The IEEE1394 is well suited to multimedia networking in homes. It has the ability to connect up to 63 devices at a bandwidth of up to 400Mbps and enables a variety of graphics, video, computer and other data to use the network simultaneously. The development of wireless IEEE1394 networking technology now allows for creativity in homes without the hassle of installing new wiring. Some recent research works in multimedia networking area are listed in the references.

The increasing computing power, integrated with multimedia and telecommunication technologies, is bringing into reality our dream of real time, virtually face-to-face interaction with collaborators sitting far away from each other. Multimedia networking promises dramatic improvements in productivity, cost, and user satisfaction, and a generation of new applications.

MULTIMEDIA NETWORKING PROTOCOLS

The use of multimedia is most visible on the Internet. Initially, the use of multimedia was constrained by low network speed, absence of suitable network protocols for transporting multimedia data, and computation limits on both server and client side. Multimedia protocols have been developed to overcome the issues detailed in the previous section. A simplified form of the multimedia protocol stack is shown in Figure 1.

Real-Time Transport Protocol (RTP): It is used on the Internet for transmitting real-time data such as audio and video. The Real-Time Transport Protocol (RTP) does not have a TCP or UDP port to communicate. It runs over UDP via an open port (generally in the range 16384 to 32767) and next higher port (odd) is used for the RTP control protocol (RTCP). UDP can not detect packet loss and restore packet sequence. RTP recover these problems using sequence number and time stamping. It also provides other end-to-end real-time data delivery services that include payload type identification and delivery monitoring. Figure 2 shows a RTP packet format.

The numbers in the parenthesis in Figure 2 indicates the number of bits. The first 96 bits are included in all RTP packets. CSRC identifier is present only when inserted by a mixer. Short description of each of the fixed RTP fields is included in the following.

- *Version (V)* identifies the version of RTP.
- *Padding (P)* if set indicates that the packet contains one or more additional padding octets at the end which are not part of the payload.
- *Extension (X)* if set indicates that the fixed header is followed by exactly one header extension.
- *CSRC count (CC)* contains the number of CSRC identifiers that follow the fixed header.
- *Marker (M)* is intended to allow significant events such as frame boundaries to be marked in the packet stream.
- *Payload Type (PT)* identifies the format of the RTP payload and determines its interpretation by the application.
- *Sequence Number* increments by one for each RTP data packet sent, and may be used by the receiver to detect packet loss and to restore packet sequence.
- *Timestamp* reflects the sampling instant of the first octet in the RTP data packet. The sampling instant must be derived from a clock that increments monotonically and linearly in time to allow synchronization and jitter calculations
- *SSRC* field identifies the synchronization source.

Figure 1. Internet multimedia protocol stack

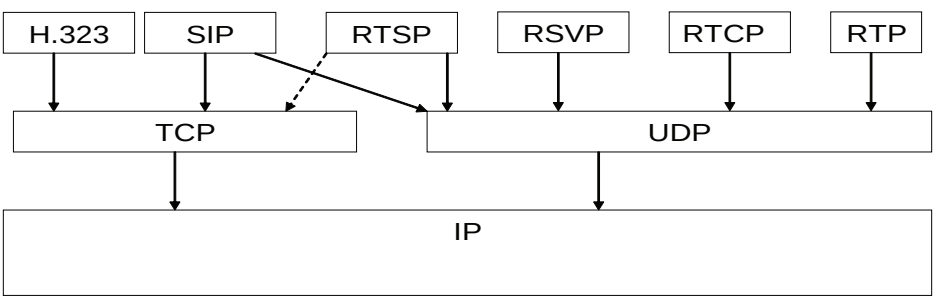

Figure 2. RTP packet format

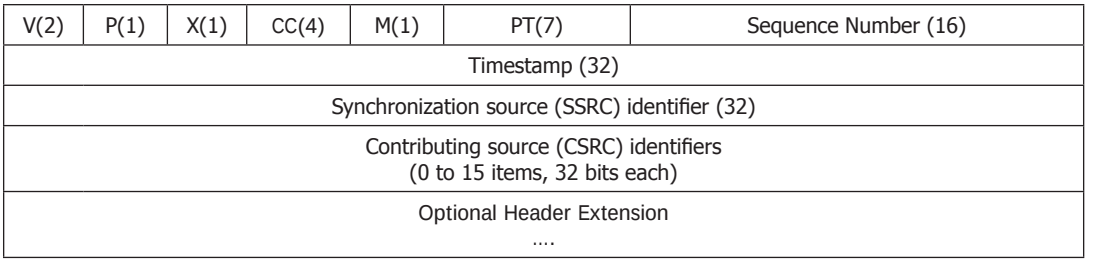

Detailed RTP format can be found in RFC3550 (http://tools.ietf.org/html/rfc3550) and payload can be found in RFC 2038 (http://faqs.org/rfcs/rfc2038.html).

Real-Time Control Protocol (RTCP): It is an Internet protocol that works in conjunction with RTP to monitor the quality of service and to convey information about the participants in an on-going session. The RTP control protocol (RTCP) is based on the periodic transmission of control packets to all participants in the session, using the same distribution mechanism as the data packets. Feedback can be used to control performance. Sender may modify its transmissions based on feedback. Each RTCP packet contains sender and/or receiver reports. Statistics include number of packets sent, number of packets lost, inter-arrival jitter, and so forth. For more details see http://www.freesoft.org/CIE/RFC/1889/14.htm.

Resource Reservation Protocol (RSVP): A host uses RSVP to request a specific quality of service (QoS) from the network, on behalf of an application data stream. RSVP carries the request through the network, visiting each node the network uses to carry the stream. At each node, RSVP attempts to make a resource reservation for the stream. RSVP does not perform its own routing; instead it uses underlying routing protocols to determine where it should carry reservation requests. There are seven messages used in RSVP: Path, Resv, Path Teardown, Resv Teardown, Path Error, Resv Error, and Confirmation. The RSVP protocol is described in RFC 2205, updated by RFCs 2750, 3936, 4495 (http://tools.ietf.org/html/rfc2205).

Real-Time Streaming Protocol (RTSP): It is a protocol for use in streaming media systems which allows a client to remotely control a streaming media server, issuing VCR-like commands (i.e., pause/resume, repositioning of playback, fast forward, and rewind), and allowing time-based access to files on a server.

Most RTSP servers use the RTP as the transport protocol for the actual audio/video data. However, a proprietary transport protocol, known as *Real Data Transport (RDT)* developed by RealNetworks, is used as the transport protocol for RTSP server from RealNetworks. The RSVP protocol is described in RFC 2326 (http://tools.ietf.org/html/rfc2326).

The H.323, SIP (for call control and signaling), and RTP, RTCP, RTSP (for audio/video) are the protocols and standards used for Internet Telephony. SIP is a signaling protocol that initiates, manages, and terminates multimedia sessions. H.323 supports H.245 over UDP/TCP and Q.931 over UDP/TCP and RAS over UDP.

MULTIMEDIA NETWORKING RESEARCH

As emerging multimedia technologies are providing higher performance available at competitive prices, they are also enabling and proliferating multimedia solutions in a spectrum of commercial and laboratory projects. Advances in computer and networking technologies have fueled the rapid growth of research and development in multimedia computing and high-speed networking. Some common research areas include:

- Development and management of real-time distributed multimedia applications;
- Audio/video applications and streaming issues;
- Protocols and technologies for building and transporting multimedia applications on the Internet;
- QOS frameworks and implementation;
- Collaborative applications;
- Multimedia synchronization in distributed environment;
- Multicasting technology and applications;
- Use of mobile multimedia over wireless network; and
- Dynamic and efficient usage of resources.

Real-time distributed multimedia environments, characterized by timing constraints and end-to-end quality of service (QoS) requirements is a challenge for the efficient management mechanisms to respond to transient changes in the load or the availability of the resources (Andreadis & Zambon, 2007).

QOS Frameworks and Implementation: In multimedia applications, media data such as audio and video are transmitted from server to clients via network according to some transmission schedules. Different from the conventional data streams, end-to-end quality-of-service (QoS) is necessary for media transmission to provide jitter-free playback. Several researchers, while dealing with the protocol and technology aspects, also have focused on the QOS frameworks and implementation issues.

Because of a wide range of application areas, the delivery of high quality video content to customers is a driving force for the evolution of the Internet (Datta, Li, & Wang, 2005; Yang, Li, & Zhuang, 2002). There are video retrieval applications with flexible user interfaces based on HTTP browser for content querying and browsing, support for both unicast and multicast addressing and a user-oriented control of QoS of video streaming in Integrated Services IP networks. Information systems' modelling methods required for the prediction of system performance and an influence of different control mechanisms on quality of service perceived by end users are related areas of research (Nang & Park, 2007; Rowe & Jain, 2005; Sebe & Tian, 2007).

The emergence of high-speed networked multimedia systems opens up the possibility that a much more diverse collection of continuous media (CM) applications could be handled in real time. Admission control in CM servers or video-on-demand systems restricts the number of applications. It is necessary to develop more intelligent mechanisms for efficient admission control, negotiation, resource allocation, and resource scheduling with an aim to optimize the total system utilization.

The traffic generated by multimedia applications presents a great amount of burstiness, which can hardly be described by a static set of traffic parameters. For dynamic and efficient usage of the resources the traffic specification should reflect the real traffic demand and at the same time optimize the resources requested. There are models, as discussed in the previous section, for dynamically renegotiating the traffic specification (RVBR) and integrating with the traffic reservation mechanism RSVP demonstrating through an example of application that is able to accommodate its traffic to manage QoS dynamically. (Syed, 2002).

SECURING MULTIMEDIA NETWORK

The security of multimedia data transmitted over a network is important for multimedia commerce. For example, in video on demand and video conferencing applications, it is desirable that only those who have paid for the services can view their video or movies. There is research suggesting different schemes to secure multimedia networks via user identities. Some scheme is composed of multimedia key distribution, multimedia encryption, and multimedia authentication to ensure that the multimedia data can be securely and efficiently distributed to multimedia users on the basis of their identities.

Authentication control mechanisms can be used to secure distributed multimedia applications. However, it is not enough to secure multimedia data broadcast on wireless, satellite or Mbone networks. Multimedia data is still needed to be encrypted during transmission. Encryption algorithms can be divided into two basic classes—*secret-key and public-key encryption* algorithms. They have distinct characteristics and are used in different ways to provide security services.

Secret-key encryption algorithms have been in use in commercial networks since the early 1970s. The U.S. Data Encryption Standard (DES) is the first secret-key encryption algorithm which has had its full specification published as a public standard. It was developed at IBM in 1976. It encrypts 64-bit blocks of data with a 56-bit key. Considering the disagreement over whether a 56-bit key is sufficiently strong, a number of secret-key encryption algorithms have been proposed to replace DES in recent years. The International Data Encryption Algorithm (IDEA), developed by Xuejia Lai and Jame Massey in 1990, is one of them. IDEA encrypts 64-bit blocks of data with 128-bit key. Another class of secret-key encryption algorithm is the stream cipher which uses a short key to generate the key-stream to encrypt a digital data stream one bit at a time.

Public-key encryption algorithms are based on mathematical functions rather than on substitution and permutation. It is asymmetric involving the use of two separate keys, in contrast to symmetric secret-key algorithm which uses only one key. The use of two keys has profound consequences in the areas of confidentiality, key distribution, and authentication. State-of-the-art public-key encryption algorithms with high security transmission performance require high processing resources when applied to high bit-rates and result not suitable for modern multimedia communications. Although existing secret-key encryption algorithms, such as DES, operate much faster than public-key algorithms, they are very complicated and involve large computations. A software DES implementation is not fast enough to process the vast amount of data generated by multimedia applications and a hardware DES implementation (a set-top box) adds extra costs both to broadcasters and to receivers.

Multimedia data security is challenging that come from two facts. First, multimedia data size is usually very large. Second, multimedia data needs to be processed in real time. Encryption algorithms with high security will put a great burden on storage space requirement and increase latency. For most multimedia applications, the information rate is very high, but the information value is very low. For some commercial applications, such as pay-per-view, very expensive attacks on the encrypted multimedia data are not interesting to the attacker because of their low information value. Breaking such encryption code is much more expensive than buying the services.

Some encryption algorithms with high security, such as DES, IDEA, and AES, when applied to high throughput multimedia data, will put great burden on storage space demand and increase latency. Thus, they may not be suitable for multimedia communications. The study related to fast video encryption can be found in many of the referenced articles, but these algorithms are only applied to video data. In view of this fact, efficient encryption algorithms for any multimedia data with appropriate security are needed. Digital signatures can be used for a multimedia user to verify multimedia data integrity which is endorsed by a multimedia server. Usually, digital signatures are produced with Digital Signature

Standard. In order to verify a DSS digital signature, the public key certificate of the signer should be submitted to the verifier for verification. Encryption algorithms and recent research has been covered in several works listed in the reference section.

Fast encryption algorithm for multimedia data, FEA-M, has been proposed by some researchers to overcome these issues. It encrypts 512 bytes of data with 512 bytes of key at a time. Cryptanalysis of this algorithm has shown that FEA-M satisfies basic confusion and diffusion design criteria. The structure of FEA-M facilitates both hardware and software implementations. Computation complexity comparison has shown that FEA-M is much faster encryption algorithm than others. It needs only about 1.5 XOR operations to encrypt one bit plaintext. FEA-M can be used to secure many multimedia applications, such as digital video and audio transmissions (Yi, Tan, Siew, & Syed, 2002).

MULTIMEDIA APPLICATIONS

We are witnessing an explosive growth in the use of multimedia in diverse application areas such as corporate presentations, communication, collaborative work, information delivery, sales and merchandising, entertainment, training and education both in distance and face to face mode, electronic commerce, simulations, digital publications, museum exhibits, games and multimedia interactive kiosks, and so forth. The application of multimedia has expanded to home libraries, magazines and newspapers, and classroom teaching. It is multimedia that is making it possible for us to remain in our homes and shop for products and services of our choices at prices of our liking. Businesses can also interact with their consumers only through their Web presence.

Some of the advanced applications of multimedia, which were otherwise thought of just as ideas, are a reality today. Some examples include videoconferencing, video phone, iPod, applications on personal digital assistants, and mobile telephones. One concept that is making fast progress is the interactive television, though it is not being used as widely because of the costs involved in moving data to and fro between the user and the service provider. If the demand for this service increases then the costs would certainly come down considerably. It is not far in future when there will be multimedia homes with virtual conference going on in one room, kids doing their homework from online databases or kids playing virtual reality games. Smart devices like portable newspapers and interactive televisions will be common for all.

In short, it will be difficult to name any application in our daily life that does not involve multimedia. In this section few of the commonly used applications are discussed.

In-Vehicle Multimedia Systems: With the growth of multimedia it is now a reality to envision an entertainment network in any automobile. Innovative A/V features are currently available on rear seat and passenger side networks, which is a driving force to bring multimedia throughout the vehicle. In-vehicle networks allow for connectivity between a vehicle and consumer electronic device. The high bandwidth, quality, and reliability requirements of multimedia have caused a demand for standardization. IDB-1394 is an international data networking standard for transmitting video, audio, and other multimedia data over an in-vehicle network that provides the bandwidth required for these applications. This is a standard suitable to enable rear-seat entertainment systems that can play DVDs, show DTV programming, and offer access to the car navigation system. The IDB-1394 standard provides a minimum bit rate of 400 megabits/second that is higher than other alternative standard such as Ethernet or MOST (which stands for Media Oriented Systems Transport). The future plan is to move IDB-1394 to 800 megabits/second, make it scalable and versatile. It will also be compatible to preserve current 1394-equipped product investment as speed and bandwidth increase.

MOST is the emerging fiber-optic network standard optimized for in-vehicle multimedia and entertainment devices. The network was founded in 1998 by many of the leading automotive manufacturers and vendors developing telematics solutions for the automobile industry, including Audi, BMW, DaimlerChrysler, Harman/Becker, Motorola, Oasis Silicon Systems, Johnson Controls, and Delphi-Delco. MOST is rapidly becoming a de facto auto industry standard for building multimedia networking products.

Yazaki North America Inc., as one of the leading provider of vehicle power and data network (PDN) solutions for the automotive industry, decided in mid-2002 to use Microsoft Windows CE in the development of in-vehicle multimedia systems. By incorporating Windows CE for Automotive, the drivers can access the in-vehicle network to control an array of potential applications, such as voice recognition and voice controls, navigation, digital video and audio, satellite TV, and video games. The MOST audio/video gateway converts data from both analog and digital sources to MOST digital data streams, providing cost-effective connectivity for portable DVD, CD, MD, and MP3 players, as well as other audio and video devices. Fully scalable, the MOST audio/video gateway also provides connectivity to CAN- and J1850-enabled devices such as radios, amplifiers, and CD changers, allowing designers to use legacy systems and components within the MOST multimedia network.

The conceptual model of Yazaki power and data networks (PDNs) consists of the following four-layer network infrastructure based on broad functionality, data-transmission speed, and corresponding data protocols. A given layer may be made up of two or more sub-networks.

- **Infotainment Layer:** It contains advanced audio and video devices, wireless phones, voice-activated systems, instrumentation sensing, and other systems requiring SAE Class D data. Transfer speed is greater than 1Mbps. It is based on the MOST data protocol.
- **Body Layer:** It provides control of lighting, HVAC, door and seat functions as well as speed control, and instrumentation. These functions are supported by low-speed, SAE Class A networks operating at lower than 10 kb/s, and SAE Class B networks running at 10-125 kb/s.
- **Safety and Mobility Layer:** It includes airbags and engine control modules plus steering, transmission, and x-by-wire systems. These systems are supported by SAE Class C and Class D networks, which provide real-time control, with operating speeds from 125 kb/s to 1 mb/s and greater.
- **Energy Layer:** It includes power generation, storage, and distribution elements (typically an alternator, battery, and under hood power distribution component).

Recently (November 2007) Fujitsu Microelectronics Asia Pte Ltd. has developed controllers, which support the IDB-1394 standard for in-vehicle multimedia networks. SmartCODEC, developed by Fujitsu Laboratories Ltd., can transmit high-resolution video without perceptible latencies, and it is possible to realize high-quality, cost-effective rear-seat entertainment. It allows transmitting video from DVD, DTV, and car navigation sources at high resolution without perceptible lag. Fujitsu plans also to expand its range of IDB-1394-compliant offerings, in view of the growth types of in-vehicle content, and to accommodate multiple data transmissions from peripheral car security cameras, and further system cost reductions (http://news.soft32.com/fujitsu-to-launch-new-chips-for-in-vehicle-multimedia-functions_5509.html?pid=5509&rate=5).

Advances in mobile communication technologies make it possible to receive multimedia content from different broadcasters. In the case of public transportation, such as in buses, trains, and airplanes, the in-vehicle multimedia content is viewed by on-board passengers. Accordingly, adaptive in-vehicle multimedia recommendation systems are useful in such situations to serve for group users. Research are being done to develop adaptive vehicular multimedia systems to provide personalized multimedia content for group users by taking care of the majority's preferences (Zhiwen, Xingshe, & Daqing, 2005).

Videoconferencing Systems: Videoconferencing is conducting a conference between two or more participants at different sites by using computer networks to transmit audio and video data. Videoconferencing systems are in place for quite some time. With the development of technology for transmission of streaming audio and video, PC-based videoconferencing, or satellite TV-based broadcast systems is becoming more affordable to general users. Until recently these were costly products accessible only to large organizations or by renting. Videoconferencing is still considered a poor alternative to face-to-face meetings. Videoconferencing systems are often used for group-to-group meetings where spatial distortions are exacerbated. In the business setting, where these systems are most prevalent, the misuse of videoconferencing systems can have detrimental results, especially in high-stakes communications. Its effects on the group dynamic are not well understood. Lots of research is being done to improve their performances.

A similar class of application that promises on-demand access to multimedia information is radio and broadcast news. Works in this areas show how the synergy of speech, language, and image processing has enabled a new class of information on demand news systems. It has the ability to automatically process broadcast video 24/7 and serve the general public in individually tailored personal casts. A medical computer supported cooperative work (CSCW) tool for medical teleconsultation supported by an open tele-cooperation architecture with modern high power workstations was implemented using distributed computing system (Holmberg, Wünsche, & Tempero, 2006).

Multimedia Office/Business: Images, animation, and audio can be added to even the basic office applications like a word processing package or a spreadsheet to emphasize important points in the documents and make them powerful tools. One of the most common uses is in multimedia presentations which are a great way to introduce new concepts or explain a new technology and reduce the design and training time of multimedia in companies. Major applications include may include: executive information systems, electronic publishing, remote consulting systems, multimedia mail, advertising, collaborative work (Jiang, Wang, & Benbasat, 2005; Yu, 2004). There is no doubt that multimedia has changed the way we do business. However, the impact of few applications, such as tele-conferencing, real-time, online, video-link, and so forth, was not as profound as was expected. Videoconference did not replace all business meetings. People would much rather do business face-to-face to feel comfortable and natural than over a video link, even at the cost of few hour's flight.

Multimedia Entertainment: The field of *entertainment uses multimedia* extensively. One of the earliest applications of multimedia was for games. Multimedia made possible innovative and interactive games that greatly enhanced the learning experience. Games become alive with sounds and animated graphics. Examples are game-show formats, hangman games, drag and drop exercises, and puzzles where students complete against the computer, another student, or the student's past performance (Chooprayoon & Fung, 2007; Magerkurth, Engelke, & Grollman, 2006; Magerkurth, Engelke, & Memisoglu, 2004).

The entertainment industry has greatly benefited from multimedia technology mainly because of their high sound and picture quality. In many occasions music is entirely created by computers and synthesis. Even most Hollywood movies now use some sort of digital imagery or editing within it. 3-D animated movies, such as Jimmy Neutron, Toy Story, and Ice Age, were created using the 3-D multimedia development programs.

Multimedia Simulation: Simulation equipped with multimedia imitates real life, situations, tasks, or procedures. Flight simulators or driving simulators may be used for training pilots or drivers without having an airplane or a car. In most cases simulation is used to train or practice decision making without having a very expensive or dangerous equipment or environment. For example, this might be used to teach manipulation of dangerous chemicals or the transporting of missiles or bombs. This type of instruction can be time-consuming and therefore costly to design and develop. Interactive simulations are the highest level of MM enhancements (Rocceti & Syed, 2003).

Virtual reality is a truly absorbing multimedia application. It is an artificial environment created with computer hardware and software. It is presented to the user in such a way that it appears and feels real. In virtual reality, the computer controls three of the five senses. Virtual reality systems require extremely expensive hardware and software and are confined mostly to research laboratories (Naef, Staadt, & Gross, 2004)

E-Commerce: The 21st century business environment is dynamic and competitive. The technology world forces on business operations all around the world to change traditional methods of business to Internet-based electronic commerce (e-commerce). E-commerce offers the most effective business opportunities in the marketplace. Electronic commerce is essential for the survival of companies in the virtual distribution marketplace.

Multimedia in Education: Delivery of content in education has gone through tremendous improvement taking advantage of multimedia. Research on relationship between cognition, learning and education through answering questions like "how does a person approach the learning of a new concept" or "how can one remember things more effectively" established positive impacts of multimedia on each step of learning cycle that involves attention, rehearsal, encoding, retrieval, attention. In the early days text-based computer assisted instruction (CAI) systems were used for delivering lectures. With inclusion of multimedia significant improvements were experienced in grabbing the attention of the learner. Lately interactive multimedia with non-linear presentations provided substantial interaction with the user. The user establishes the concept in mind more firmly by receiving feedback of the activities performed for different levels of difficulty selected by the user or the system based on the evaluated skills. Application of multimedia is varied and may be accommodated for different learning styles (e.g., association vs. experimentation; auditory vs. visual) at different level with different expectations and outcomes. For example, multimedia lessons may be developed for children aimed at visual memory development, which is a very important step in the development of children in the early ages. Different issues related to multimedia in education and recent research has been covered in several works listed in the reference section.

Multimedia Network for Healthcare: One leading healthcare provider, the Northwestern Memorial Hospital, deployed a next generation 3Com multimedia network consisting of industry-leading enterprise switches and supporting systems to access patient-critical medical applications and data. The aim was to improve medical, scheduling, and billing processes to bolster patient care and satisfaction. The system was designed to provide the staff with up-to-the-minute patient records and diagnoses and the most sophisticated medical services available. The network would provide caregivers with a fast and reliable flow of patient information for timely and effective healthcare and also support the newest multimedia teaching technologies. The network system may also be incorporated into the enhancing and ongoing training of medical students with multimedia applications. It also has important features that the students are able to view live surgeries and other operating room procedures for their desktops (Cucchiara, 2005; Ebadollahi, Coden, Tanenblatt, Chang, Mahmood, & Amir, 2006; Halle & Kikinis, 2004; Kulkarni & Öztürk, 2007).

Voice over Internet Protocol (VoIP) over digital subscriber line (DSL) offers the ability to provide both voice and data over a single copper loop, cost effectively and with flexibility and functionality. DSL's dedicated lines provide increased security and guaranteed bandwidth that is comparable to that offered by T-1 and frame relay circuits but at a lower cost.

Internet Telephony: Internet telephony is the technology that makes it possible to have a telephone conversation over the Internet. This technology also includes voicemail online and conference calls without being tied to any area code. Different Internet phone services are: PC-to-PC, PC-to-Phone, and Phone-to-Phone. Until recently, Internet telephony was characterized with poor voice quality and long

time delays in transmission. With elimination of these problems Internet telephony's voice quality has become competitive to its rival PSTN. Internet phone services have grown from technical novelty to a competitive threat for traditional circuit-switched telecommunications. It offers one common service combining voice, video, and data traffic by adopting IP as a common protocol and merging different network structures in one comprehensive medium. While most Internet applications are seen as another or additional source of revenue to the Interexchange Carriers (IXC's), Internet telephony, or the transport of voice over the Internet, it might pose a potential threat from the view point that the circuit-switched technology will be obsolete and be considered for an updated technology. Traditional carriers and telcos are beginning to feel similar pressure predicted by Forrester Research that by the year 2004, U.S. telephone companies alone would have lost some $3 billion to Internet telephony. From the users' point of view, it might mean an improved service at a steeply discounted rate, especially for long-distance calls.

With the availability of modern development tools, it will not be a big mistake to make assumption that today the multimedia end product is only limited imagination of the developer and requirement specification of the customer.

PEER-TO-PEER (P2P) MULTIMEDIA NETWORK APPLICATIONS

In both academia and industry, peer-to-peer (P2P) applications have attracted great attention. In a peer-to-peer (P2P) overlay network, a large number and heterogeneous types of peer processes are interconnected in networks (having wide varieties of computing and network resources) with an aim to exchange multimedia contents, such as movies, music, pictures, and animations, and so forth, in a reliable and real-time manner. It is different from client-server based systems in a way that the peers bring with them server capacity. Multimedia streaming is a key technology to realize multimedia applications in networks. The P2P streaming applications, such as PPLive, UUSee, are on the rise. These enable the P2P file sharing/streaming application inexpensive to build and excellent in scalability. Following are some of the successful and well-known P2P file sharing applications.

- BitTorrent
- Gnutella
- Kazaa
- Napster
- PPLive
- Skype

Some statistics indicate that P2P traffic accounts for almost 70% of Internet traffic.

MULTIMEDIA DATA MINING/MULTIMEDIA RETRIEVAL

Multimedia and data mining are two very interdisciplinary and multidisciplinary areas that are experiencing rapid developments in recent years. While multimedia is facing the challenge in handling data due to the enormous growth in content and data mining has become a popular way of discovering new knowledge from large data sets, accordingly multimedia data mining emerged as a discipline that brings together database systems, artificial intelligence, and multimedia processing. Multimedia retrieval/multimedia mining makes it possible to retrieve desired information, analyze characteristics of an information set,

and discover knowledge hidden in vast amounts of multimedia information. It is, therefore, is a technology necessary for the effective use of multimedia information. Analysis and/or mining of knowledge are very important for marketing, product design, science domains, and various other areas. Museum artifact retrieval systems and video retrieval systems in the education field can be very effective when equipped with data mining capabilities.

ISSUES, TRENDS, AND EFFECTS OF MULTIMEDIA

With the increased availability and ease of access to electronic multimedia information, new challenges are arising in all areas such as data management, retrieval, synchronization, and transportation of large volumes of media generated data. Also we need to address a number of technology, management, and design issues.

Managing Multimedia Projects: Organizing and managing multimedia IT project remains a challenge. Creativity is an important key word in developing multimedia IT. It is very difficult to measure the level of creativity in each of the players of a project, namely the employees who are involved in creating and delivering the project within the given dead line and the clients with varying expectation of the creativity. For a desired good output the employers need to ensure a creative environment so that the employees can think creative and work at their own pace. The fact remains that "some employees can turn on creativity like a light switch and others need creativity to come to them".

Interoperability is also a very important issue. The applications need to be coded in one standardized coding format, making them accessible to a whole range of end-systems supporting real-time audio/video stream and synchronization. There also need to be a set of protocols defined to implement transfer of all messages and dataflow in the system. Gateways will have to be specified to integrate various digital services and support the corresponding formats.

In multimedia applications, digital imagery and video has expanded its horizon in many directions, resulting in an explosion in the volume of image, audio, and video data required to be organized and retrieved. Accordingly, we are witnessing a great increase in research on multimedia retrieval, which has paved the way for new techniques and fascinating applications (Datta, Li, & Wang, 2005; Nang & Park, 2007; Rowe & Jain, 2005; Sebe & Tian, 2007; Yang, Li, & Zhuang, 2002).

Managing Multimedia Resources: Because of large file sizes of audio and video contents, communication over the Internet involving multimedia data consumes lots of network bandwidth, occupies large storage space, and requires high processing time both on the client and on the server side. With large multimedia files the maximum serving capacity of a server decreases exponentially, which is true even in case of an infinitely fast server. It is said, "The backbone of the Internet may have been designed to withstand nuclear assault, but it will never survive the onslaught of multimedia on the Web". The large multimedia file sizes not only consume more bandwidth during transmission, they occupy connections for long time, which causes delay to other real-time data transfers and also decrease the total number of connections available at any one time. In the long run, these connections make it easier for a server to run out of TCP/IP kernel resources (http://www.webdeveloper.com/multimedia/multimedia_dark_side.html).

Trends in Mobile Multimedia: During the last decade the networking speed has grown from 10 megabit to gigabit range, but the explosive growth in the number of the Internet users has caused the amount of traffic to grow several times more. At the same time due to the significant advances in the VLSI technology, there is an increasing demand for portable multimedia appliances capable of handling advanced algorithms required in all forms of communication. Over the years, we have witnessed a steady

move from stand-alone (or desktop) multimedia to deeply distributed multimedia systems. Wireless computing is taking the world by storm to serve our information need. So, there is a need for efficient mapping of the requirements of multimedia systems onto mobile networking environments. The success criteria for a mobile application design is to find the best mapping onto the architectural resources, while satisfying an imposed set of design constraints (e.g., minimum power dissipation, maximum performance) and specified QoS metrics (e.g., end-to-end latency, jitter, loss rate) which directly impact the media quality. Applications are evolving in order to support today's mobilized workplace and lifestyle. But multimedia systems yet need to become more adaptive or scalable with respect to the fluctuating network environment (Cai, Shen, & Mark, 2006; Farnham, Sooriyabandara, & Efthymiou, 2007; Fernando, 2006; Koutsakis, 2007; Pham & Wong, 2004; Thwaites, 2006; Verkasalo, 2006).

Trend in Multimedia Research: Multimedia research will continue to address the crucial problems that are evolving every day as attempts are being made to bring the dream applications into reality. Some recent research is included in the reference list. Research works in multimedia has been extended from software development to concept of probabilistic design for multimedia embedded systems, which systematically would incorporate performance requirements of multimedia application, uncertainties in execution time, and tolerance for reasonable execution failures (Hua, Qu, & Bhattacharyya, 2007). Because of the dominant computing workload of multimedia applications in computer systems and in wireless-based devices and due to their repetitive computing and memory intensive nature, Lanuzza, Margala, and Corsonello (2005) suggested to take effective advantage from processor-in-memory (PIM) technology and proposed a new low-power PIM-based 32-bit reconfigurable datapath optimized for multimedia applications.

Social Impact: One other important aspect is the social implications that multimedia-based applications may have. The positive aspects are more obvious than the negative ones. With so many facilities readily available at homes, offices, and shops, there are several questions remain yet to be answered such as, how the reduction in human contact will affect the social behavior—will the offices, the playgrounds, or the malls have a deserted look? Because, the people prefer to work from home or they would spend more time on games and virtual reality avoiding outdoor exercises, breathing fresh air or they prefer ordering through interactive television while watching a movie. There is always a balance which can be found to benefit from a developing technology like multimedia and it sure will make information and communication easy to access and use.

Human-Centered Multimedia—Cultural Impact: The wide acceptance of multimedia may be credited to the human-centered characters inherent in media combinations. However, the cultural part of the human-centered approach did not get much consideration in design of multimedia development tools and applications. We often forget that the development of multimedia interfaces and communication are language and culture-specific. The users feel much comfortable when they can act to the cultural context to which they belong (Arts, 2004; Dimitrova, 2004; Rowe & Jain, 2005). Examples of how culture affects content production and automatic analysis techniques may be found at http://www-nlpir.nist.gov/projects/trecvid/ (The TREC video retrieval evaluation, 2005). Recent trends are to align technical development with social and cultural development involving new models that embraces multiculturalism and recognizes the human impact.

CONCLUSION

In the span of the last two decades, we have witnessed dramatic increases in the use of digital technologies for information storage, processing, and delivery. The potential of multimedia has demonstrated

to be one of the most fascinating and fastest growing areas in the field of information technology. The current technological impacts of multimedia are much larger then most people think it is. Until even recently it was not unusual to be frustrated with a multimedia project running on a slower computer because it didn't run at a desired speed with desired quality. Multimedia consumes a lot of computer power to run effectively and influences greatly in the decision of people when purchasing new computers. Now many people can afford to get the latest and fastest computer for video editing of their home movies. Businesses can now understand their markets more in depth than ever before enabling them to improve quality of production, products, services, and consumer satisfaction.

Multimedia is playing and will continue to play a very important role in today's visual society. Interactive multimedia will grow in maturity and popularity on the gigabit networks. With technologies continuing to push toward the seamless integration of multimedia and the Internet, computer speed gaining a super-speed, promise of gigabit home networks looming on the horizon and improved compression techniques emerging at a fast pace, we can confidently conclude that multimedia productions are yet to show their full potential—the multimedia of the future.

Section 1

Fundamental Concepts and Theories

This section serves as the foundation for this exhaustive reference tool by addressing crucial theories essential to the understanding of multimedia technologies. Chapters found within these pages provide an excellent framework in which to position multimedia technologies within the field of information science and technology. Individual contributions provide overviews of multimedia education, multimedia messaging, and multimedia databases while also exploring critical stumbling blocks of this field. Within this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the research and application of multimedia technologies.

Chapter 1.1
Fundamentals of Multimedia

Palmer W. Agnew
State University of New York at Binghamton, USA

Anne S. Kellerman
State University of New York at Binghamton, USA

ABSTRACT

This chapter introduces multimedia, defined as interacting with information that employs most or all of the media: text, graphics, images, audio, and video. Students and faculty need to learn to create and use high-quality multimedia documents, including references, lecture materials, reports, and term papers. The authors provide a framework for understanding multimedia in its rapidly changing context. They discuss a wide spectrum of multimedia end-user devices that range from smart cell phones and powerful PCs to intelligent cars and homes. They also propose a vision of pervasive multimedia any time and anyplace, and discuss related issues, controversies, and problems. Typical problems are excessive complexity and a plethora of choices that paralyze many potential users. The chapter concludes with a discussion of possible solutions to major problems and probable future trends.

INTRODUCTION

Multimedia is interacting with text, graphics, images, audio, and video. Creators and users of multimedia employ end-user devices that range from PCs and interactive televisions to smart phones and PDAs. People exchange multimedia using delivery methods such as dial-up and cable-modem access to the Internet, mailed DVDs, and Internet2. Multimedia communications can be more effective and interesting than communications that are limited to text.

Most of us will create, as well as use, multimedia throughout the remainder of our lives. Almost all future work and everyday life will involve dealing with multimedia wherever we are by using the end-user devices at hand. Examples of use include sending images to Aunt Lizzie by way of a cell phone, and writing and wirelessly posting a report on the Internet concerning worldwide petroleum sources, while standing near an oil well in the Middle East.

The objectives of this chapter are to:

- Provide a framework for efficiently acquiring new knowledge and skills in the rapidly changing multimedia arena;
- Discuss a vision for effective multimedia creation and use, by nearly everybody, nearly anywhere, and at any time;
- Delineate the major issues, controversies, and problems that litter the path toward achieving that vision; and
- Discuss some corresponding solutions and recommendations, many of which involve skills that instructional technologists, teachers, and students need.

BACKGROUND

Figure 1 shows a high-level view of people and components involved in creating and using multimedia. Some providers create multimedia content, information, titles, or applications that employ multiple media and are interactive. These authors create this content by employing end-user device hardware and software. They then typically store the resulting content on servers. The content is delivered to other, often different end-user devices employed by users, customers, or readers by means of delivery networks that range from mailing diskettes or DVDs to using local area networks or the Internet. By no means are all authors professional creators; the most interesting aspect of multimedia is that it is now sufficiently inexpensive and almost sufficiently easy that almost anybody can create as well as use multimedia. Other providers include a wide range of individuals, companies, and governments that play a wide variety of roles. For example, some providers provide products and services that are important to the delivery of multimedia to end-users.

Figure 1 is a framework in which you can add newly acquired knowledge about multimedia. For example, if you think you might want to provide an on-demand multimedia tutorial for your students to use from their cell phones, you need to have an authoring end-user device, a way to deliver this content to your users, and tools to allow you to create content for the desired end-user platform. You should know that, at least in the US, wireless delivery will be problematic. The good news is that network providers are improving their products and services, with the goal of handling wireless high-quality images and video within the next couple of years.

Creators and end-users employ a variety of tools. Some tools operate on the individual media.

Figure 1. Framework

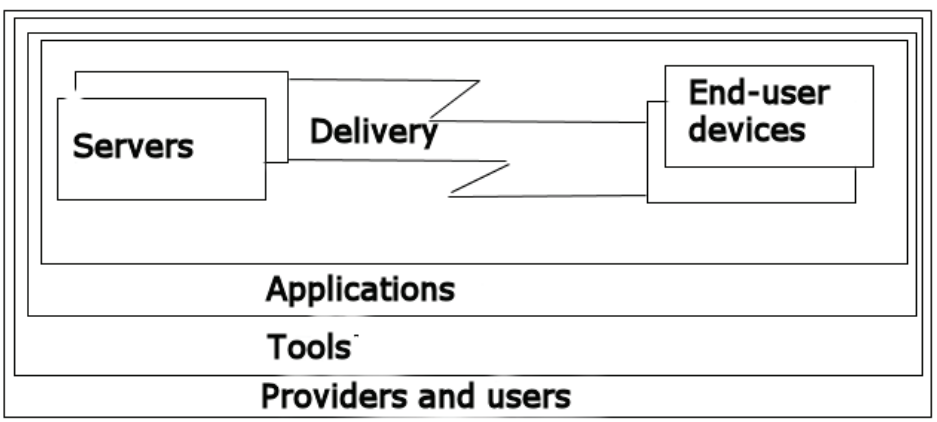

Table 1. Typical multimedia software

Medium	Tools
Text	Microsoft Word, Corel WordPerfect, Tex, Latex
Graphics (i.e., vectors)	Corel Draw, Adobe Illustrator, Macromedia Fireworks, Adobe ImageReady, Macromedia Flash
Image (i.e., bitmap)	Adobe Photoshop, Jasc Paint Shop Pro, Macromedia Fireworks
Audio	Sony Sound Edit Pro, Sony Sound Forge for Windows, Sony Acid, Cakewalk products
Synthetic Video (animation)	AutoDesk AutoCAD, Discreet 3D Studio (MAX), Virtus 3D Website Builder, Macromedia Flash, Electric Image Amorphium Pro, Alias Maya
Captured Video	Adobe Premiere, Avid, Media 100 products, Ulead Media Studio Pro, Microsoft MovieMaker, Apple iMovie
Authoring Systems for All Media	Macromedia Director, Macromedia Dreamweaver, Click2learn Toolbook, Microsoft Front Page, Adobe Page Mill, Microsoft PowerPoint with Producer

Other tools, called multimedia authoring systems, assemble multimedia media and add interactivity. Individual media tools include editors for text, images, graphics, audio, and video. Tools that generate HTML with associated Web browsers are examples of multimedia authoring systems. Table 1 provides some specific examples. A great many can be found at Maricopa Community College's Web site, Multimedia Authoring (Maricopa Community College, 2004).

One correct conclusion that you can draw from the table's examples is that creators of multimedia often need to obtain and master separate tools for each medium, as well as one or more authoring tools that combine several media. To the extent that multimedia creators and users are different people, users are also faced with multiple choices of tools with which to play back the media, such as browser plug-ins for a variety of streaming audio and video formats. Users may also need one or more authoring systems' so-called "run-time environments," if not the full authoring systems.

Multimedia tends to be large in terms of storage space and network bandwidth. Whereas a text page occupies only about 3,000 bytes, five minutes of high-quality video can occupy up to 1 Gigabyte (1 GB). Solutions involve squeezing multimedia by compressing it using a range of sophisticated technologies. As you can see from Table 2, desktop computers routinely come with 80 GB of hard-drive storage space, whereas mobile devices have far less space. Multimedia requires networks that are fast enough to ensure that multimedia plays correctly. Cable modems, Digital Subscriber Lines, and special techniques of streaming are required and often perform adequately, but note the typical network data rate of PDAs in Table 2.

Assume that you have set up an environment such as the one in Figure 1. Now comes the really

Table 2. Typical end-user devices

Property	Desktop Computer	PDA and Cell Phones
Storage	80 GB hard drive	128 MB Flash RAM card
Processor clock rate	2.4 GHz	400 MHz
Operating system	Windows XP	PocketPC
Display diagonal, inches	17.0	3.8
Network for delivery	Cable modem, wireline, typical speed of 400 K bits/sec	Wireless, typical speed of 16 Kbits/sec

Table 3. Sample content-preparation guidelines

Guideline
Provide user-selectable options for multiple learning styles.
If you present text and audio on the same page, make sure that both use the same words. Nobody can read one set of words while listening to different words.
Remember that any movement on a page, such as video or animation, strongly distracts a user from non-moving information such as text.
Use colors to facilitate readability, appeal to different audiences, and reflect different cultures.
Use background music sparingly, to set a mood.
Prepare text for skimming rather than for reading long passages in detail. Computer monitors tire the eyes because they have resolutions that are much less than resolutions of printed pages.
Organize multimedia information carefully and consistently.
Have important information no more than three clicks (or levels) deep.
Do not use copyrighted media in any content that you sell, unless you obtain the owner's permission. Be careful what copyrighted media you use, even in an educational context.

For extensive details, consult *Distributed Multimedia* (Agnew & Kellerman, 2002).

challenging part: creating the content or coaching others to create content. If you are coaching students, you should know that creating multimedia projects can help your students to achieve goals that include developing higher-order thinking skills and interpersonal skills, learning content by engaging multidisciplinary subjects, and developing technical competence and media literacy that will empower the students throughout their lives (TeleEducation NB, 2002). Furthermore, employing multimedia will allow you to improve students' efforts outside formal classroom settings and allow you to piggyback on these efforts inside the classroom. Victory, however, is not merely receiving any old PowerPoint presentation, even with audio, animation, and video. Having an

arsenal of past examples and setting up Olympic scoring of students' results (Agnew, Kellerman, & Meyer, 1996) helps elevate the standards of content quality. Guidelines such as those in Table 3 can help you as either a coach or creator.

ISSUES, CONTROVERSIES, AND PROBLEMS

Early adopters and pioneers routinely create multimedia. Today, with affordable hardware and software, people who are not media professionals can prepare interactive documents that contain multiple media. They can communicate using these media either in real time, using streaming, or asynchronously, using e-mail. Using multimedia tools, they can structure their information to greatly facilitate understanding. They can send this multimedia information to remote locations, with some certainty that it will be received rapidly and understood successfully. Tomorrow, lacking such skills will seriously impact almost all professionals' and students' lives, job satisfaction, and job performance. Content created by early adopters and pioneers has made multimedia literacy part of the expected price of admission to many roles.

Complexity and too many choices stymie the rest of us. Unfortunately, arcane skills are still required to set up digital environments and then use them for serious information preparation or even for living-room enjoyment.

Our professional colleagues and teaching friends confirm that multimedia is changing fast and furiously, making it difficult for them to keep up in a field that they view as diverging from their respective professional areas. They are elementary school teachers, biology teachers, instructional technologists, literature professors, and so forth. Nevertheless, new multimedia capabilities are superb ones that such professionals need. What best characterizes humans, all over the world, is our ability to communicate orally and in writing. Multimedia can make this communication even better, if done well.

Dramatic price declines in software and hardware allow many more of us to set up the environments we need to both create and use multimedia. For example, we have watched PC cams (small video cameras that connect to PCs for both storage and control) drop in price below $100, then below $30, and now below $10. The difficulty all of us find is that to learn what we specifically need to know, we must either spend hours on the Internet or buy books, often blindly. If only the cost and time spent learning to use the affordable hardware and software were decreasing as well.

Vendors have conflicting motivations. It would be easier for users if Microsoft could indeed integrate all required support into its operating system. Governments and competing vendors have widely divergent motivations. As a result, authors are required to either guess at which formats and data rates their audience requires or supply several different views of the same content.

Book stores display many shelves of books on different media and on enhancing Web pages. You are led to believe, with some truth, that to learn to create multimedia, you need a yard of books. Very few books tell how to create meaningful content where content is targeted to academic or serious professional uses.

Mismatch of equipment between home and school. People are using digital cameras, both standalone and inside cell phones, in record numbers. They are learning how to use them on their own, just blundering through. Electronic gadgets including computers at home are proliferating. Home computers tend to be good ones that far outperform what is available in most K-12 schools and many universities. In school, children are exposed to old equipment without getting sufficient quality instruction in its use and without educators taking advantage of the motivational aspects of using the equipment to enhance education. The Salvation Army prefers

to reject any computer that is more than three years old; can schools do the same?

Creating high-quality content is difficult today, and few are experienced in it. The available tool often drives the content, rather than conversely. A tragically famous example of this is NASA's chart justifying its tests of foam striking a Space Shuttle's wing. The authors produced bullet after bullet of PowerPoint text at random levels of hierarchy and importance. Unfortunately, they buried the only important fact (that their test set-up had been totally unrelated to the real world) in a sentence fragment at the bottom of the page, rather than making it the title, or at least phrasing it as an unambiguous complete sentence.

Dr. Edward Ayers (2004) understands that few scholars have done what he has done over the last decade, namely scholarly research on multimedia narration (Ayers, 2004; valley.vedh.virginia.edu).

SOLUTIONS AND RECOMMENDATIONS

Early adopters and pioneers routinely create multimedia. To help students and teachers achieve multimedia literacy as part of life's expected price of admission, educational technologists must continue learning, coaching, and mentoring the rest of the academic community. Academics in universities must work together. As an example of the kinds of successes cooperation can have, Dr. Meyer (a computer science professor) and Dr. Driver (a literature professor) worked together to inspire literature students to compose multimedia documents. Each provided relevant expertise (Driver & Meyer, 1999).

Young people are intrinsically early adopters and pioneers. While it is charming when students teach teachers, it is teachers who can best apply the required pedagogy to achieve the desired results.

Complexity and too many choices stymie the rest of us. A viable approach is to identify a small set of tools and stick with it for several years, ignoring incremental advances in hardware and software. This includes taking advantage of tools that ship with major software. For example, both Microsoft and Apple ship moderately functional video-editing software as parts of their current flagship operating systems.

Mismatch of equipment between home and school. Parents need to get involved, working with teachers to encourage home equipment use for creation of rich media content in support of pedagogical goals.

Creating high-quality content is difficult today, and few are experienced in it. As it becomes easier to assign multimedia, this will become more common. Future teachers need coaching in how to use multimedia in the classroom, as in the text, *Multimedia in the Classroom* (Agnew et al., 1996). Teaching teachers in colleges and universities does not consist of imparting isolated media skills, but rather of showing how to put it all together in a learning environment. One key is exhibiting exemplary multimedia content achieved by relevant people. It is not useful to present George Lucas's work for students to emulate; work produced by students in prior years is far more helpful. Like many subjects, the hardest part of teaching multimedia is getting started.

Teachers need to develop pedagogical goals for both teaching basic multimedia literacy and using multimedia to teach other subjects. This requires that they understand what is required to create and use multimedia to achieve pedagogical goals and that they then implement paths to reaching these goals that are consistent with their existing environments. They must be able to assess results along multiple dimensions. Merely using multimedia is not enough when the goal is quality content supported by rigorous arguments. Teachers and educational technologists will routinely need to advise, recommend, approve, and obtain parts of the framework required for multimedia.

Educators will need to improve their multimedia creation and playback environments, as prices and quality of tools continue to decline, and in step with the mainstream and with overall mission objectives. For example, the military now uses high-speed computers, high-bandwidth delivery connections, and sophisticated multimedia simulations to instruct soldiers on how to carry out missions. Whereas K-12 teachers might have more modest requirements, everyone involved in multimedia must learn to communicate intelligently and efficiently with vendors of multimedia products and services. A major part of this is learning when to search the Web and when to telephone a help line. Experience will assist educators in knowing what multimedia they and students can produce and use with what they have on hand, and what multimedia is suitable for what their intended users will have on hand.

Everyone should be able to recognize and produce quality multimedia content. Those who can do this will need to be generous with their time and talents, and help others to do likewise. Available tools must not drive content in undesirable directions, such as PowerPoint's leading from sentences to sentence fragments to sloppy thinking. Using tools must not be allowed to become the end in itself.

Suitable goals include preparing teachers and students who are routinely able to create and deliver a multimedia proposal, resume, presentation, set of instructions, or report using appropriate selections from alternative media. In many cases the media will need to be suitable for nationwide or even worldwide distribution over the Internet. This requires some understanding of the available bandwidths of connections that range from reasonably fast broadband to abysmally slow cellular wireless. It also requires selection between real-time and asynchronous communication and suitability for a wide variety of end-user devices.

Creating multimedia requires people to be able to:

- Acquire and prepare images and graphics for inclusion in documents;
- Repurpose slides and analog photos into digital forms for playback on TVs, PCs, cell phones, and PDAs;
- Create and incorporate video using either economical PC cams or high-quality Mini-DV camcorders;
- Prepare animation for illustration and instruction; and
- Employ voice recognition software for communicating with devices that are too small to have workable keyboards.

Examples of specific skills include:

- Converting media from one form to another for use in various situations and on various devices;
- Using tools that allow processing of several media files in one batch, such as in converting an entire folder of several images from one format to another at once; and
- Organizing raw and completed information for effective later re-use and collaborative use.

All of these skills require particular attention to what is actually feasible to achieve meaningful results.

Moreover, everyone must know about the rights that educators and others have with respect to using media created by others. Rights may differ between content used as is and altered content.

FUTURE TRENDS

For better or for worse, future uses of multimedia in educational and other contexts will be driven by improvements in technologies. Moore's Law famously predicts that processor power and internal memory capacity will continue to double every year or two, without significant increases in

cost. Less famously, other important technologies are improving at even faster rates. A decade ago, the available hard drive space on a typical home computer sufficed for storing barely 30 minutes of moderate-quality video; now a typical computer can store about 30 hours of high-quality video. Increasingly, economical hard drives have allowed many users to afford personal video recorders, such as TiVo, as well as sophisticated in-home video editing. A decade ago, transcontinental telephone connections were so scarce and expensive that long-distance telephony was a cash cow; now a glut of worldwide fiber-optic cable bandwidth allows Dell to route help-line calls to Indonesia as cheaply as to Indiana.

Companies including Intel, IBM, and AT&T are severely threatened by rapid technological progress that gives customers the opportunity to pay vastly fewer dollars for the same products and services. Many companies see multimedia as their only hope for convincing customers to purchase far more products and services, for at least the same number of dollars. It works. Most owners of digital still cameras now use more hard-drive space for storing images than they used for all purposes just a few years ago. New, tiny video cameras that temporarily store video on expensive flash RAM cards will permanently fill up even more storage space on hard drives.

This trend toward rapid improvement in technologies means four things to us all, as creators and users of multimedia. First, we must beware of pressures to use more of the products and services that do not benefit us, merely because they are increasingly economical. Second, we must try to make excellent use of newly affordable methods for achieving our goals. Third, we must encourage providers of multimedia products and services to make major improvements in ease of learning and ease of use, rather than merely dumping in more and more capabilities with attendant increases in confusion. Fourth, we must continually keep abreast of research on assessments of multimedia technologies, especially ones which include best practices. One way to keep abreast is to subscribe to Kotlas's newsletter, *CIT Infobits* (2004) and review the list she compiled on Assessments of Multimedia Technology in Education.

CONCLUSION

We will all communicate using technologies that range from today's e-mail and Word documents to tomorrow's video instant chats. Each communication will be significantly enhanced by our ability to easily and effortlessly use appropriate media and to allow the recipient to selectively access content in a variety of forms. We will build on skills acquired at home, in K-12 schools, and in higher education. We can expect to learn continually as technologies improve. As vendors expect to sell more of their hardware and software, we hope their motivations will include making equipment easier and quicker to learn and use, as well as more economical to buy. We must help one another, even if it requires cross-disciplinary activities. The best authors need to take advantage of multimedia to create multimedia and to help the rest of us learn to create it and use it.

Chapter 1.2
Digital Multimedia

Neil C. Rowe
U.S. Naval Postgraduate School, USA

INTRODUCTION

Multimedia data can be important assets of government computer systems. Multimedia data can be documents, statistics, photographs and graphics, presentations, video and audio of events, and software. Examples include maps, video of meetings, slide presentations by consultants and vendors, graphs of budgets, and text of regulations. Video of meetings of legislatures and other government organizations is particularly valuable as it makes government processes more visible to citizens and can encourage trust in government. Multimedia is also particularly valuable in presenting geographical information (Greene, 2001), a concern of all governments. Added multimedia can also be used to more effectively deliver information to people, as with films, animations, sound effects, and motivational materials.

Multimedia information is important for digital government because it is often a more natural communication mode for people than text. It is thus important that government be responsive to the needs and desires of citizens by providing it. Much of the world is illiterate, and the ubiquity of television means even the literate often prefer watching video to reading text. Some citizens have special needs: Blind people need audio, and deaf people need images. Video and audio also convey information beyond text: A video of a legislature meeting contains subtleties not apparent from its transcript. Research has shown that multimedia is especially good at conveying explanatory information about functional relationships in organizations (Lim & Benbasat, 2002). Research has also shown that people learn better from multimedia presentations than from conventional classroom instruction, and the multimedia provides a consistent experience available at any time unlike human instructors (Wright, 1993).

BACKGROUND

The management of multimedia data entails considerations not encountered with data that is solely text (Vaughan, 2003). The main problem is data volume: A typical report can be stored in 20,000 bytes, but a typical 20-centimeter square image requires 500,000 bytes to represent adequately, an audio clip that is 1 minute long requires around 1,000,000 bytes, and a typical 3-centimeter square

video clip that is 1 minute long requires around 50,000,000 bytes. Compression techniques can reduce storage requirements somewhat; however, media that can be compressed significantly tend to be merely decorative and not very useful for digital government. Multimedia size is especially a problem when transferring media between computers, especially with the limited data rates of conventional telephone lines and modems (Rao, Bojkovic, & Milovanovic, 2002). So, since digital government cannot be sure what technology its citizens have, it must be conservative in its use of multimedia.

Distributed database technology (Grosky, 1997) can help manage multimedia data efficiently. However, the human side of multimedia management requires a different set of skills than those of most computer support staff. One needs media specialists familiar with the problems of the technology, including some staff with art training to address the aesthetic issues that arise. Much multimedia management is time consuming, so adequate personnel must be available. Government can also choose to actively encourage the development of a multimedia-supporting infrastructure by its industries (Mohan, Omar, & Aziz, 2002).

INDEXING AND RETRIEVAL OF MULTIMEDIA

A first issue in using multimedia data is finding it. Citizens often want to retrieve quite specific multimedia objects to meet their needs, and they can do this with a browser or a search engine (Kherfi, Ziou, & Bernardi, 2004). This requires metadata describing the media objects such as size, date, source, format, and descriptive keywords. A browser can provide a hierarchy of media objects that users can navigate. This works best when media objects can be described in just a few words, or are characterized along a single dimension like date or place. Otherwise, a keyword-based search engine is necessary, such as that provided by commercial services like Google but adapted to search only government data. Accommodating a broad range of citizens means keeping extensive synonym lists for keyword lookup so that many possible ways of specifying the same thing will work. In some cases, a graphical specification may be a good way for the public to specify what they are looking for, such as a visual timeline or geographical display on which they click on the location they want.

Unfortunately, it is difficult to index and search nontext media for its contents. Segmentation by identifying shapes within images can be tried, but it is time consuming and often unreliable. So captions on media objects (text that describes them) are valuable (Rowe, 2005). They can be directly attached to a media object or located near it in a document. Captions directly attached include the name of the media file, descriptive keywords, annotations describing the object like the *alt* string associated with Web media, the text of clickable links on the Web that retrieve the object, text directly embedded in the media like characters drawn on an image, and data in different channels of the media like narration or closed captions for video. Captions indirectly attached include text centered or in a special font above or below the media, titles and section headings of the document containing the media, special linguistic structures like "The photo shows …," and paragraphs above or below the media. Caption text can be indexed for a more precise keyword search than that obtained by just indexing all the words of the enclosing document (Arms, 1999). This is what the media search engines such as the image searchers of Google and AltaVista do, though their success rate at finding images is not as good as their success rate at text search. Media retrieval is, however, an active area of research, and new developments are appearing frequently.

DELIVERY OF MULTIMEDIA

Multimedia can enhance documents in many ways. It can enliven information, and this is helpful for the often-unexciting information provided by governments. But the primary concern of government must be for media that convey important information of their own. Mostly, this means the delivery of multimedia information from the government to its citizens, though there are also issues in the collection of information by government (Cheng, Chou, Golubchik, Khuller, & Samet, 2001) and communications within government.

Broadcast technology is the traditional method for a government to disseminate media through newspapers, radio, and television. Broadcast is a one-way technology. This is fine for announcements and authoritarian governments, but interactivity is very important to a responsive and effective government. So, the Internet and especially the World Wide Web are increasingly preferred to deliver user-selected information and permit the completion of forms. The Web is well suited for multimedia. It permits the embedding of pointers to multimedia content in documents with much the same ease as text. Web multimedia can range from informal illustrations to media retrieved from structured databases in response to queries entered on dynamic Web pages. Media is particularly helpful for the illiterate as graphical interfaces can enable access to the full power of computers without the necessity of words.

A key issue for digital government is the choice of media formats. Government information systems intended for only internal use can follow very few mandated formats for interoperability. But much multimedia is for the public, and the public uses a diversity of computers, software, and networking services, and accessibility to all citizens is important. So copies of important multimedia in different formats are essential. Web images are currently mostly in JPEG and GIF formats, with some in PNG format. Audio and video are more diverse: Currently popular audio formats are WAV, RAM, MID, and ASX, and currently popular video formats are MPEG, SWF, MOV, FLI, AVI, and MP3. Multimedia can also be software in various formats. Not all these formats are supported by all Web browsers, so it is important for government to provide free viewer software for downloading so citizens can view any of its multimedia. This generally restricts governments to using formats that have free open-source software for reading or viewing them.

Multimedia software of particular interest to government organizations is groupware, supporting collaborative activities of groups. It can be used to run meetings of people at widely scattered locations so participants can see, hear, and read comments by other participants. Groupware requires transmission of video, audio, and graphics between sites (Klockner, Mambrey, Printz, & Schlenkamp, 1997).

STREAMING MULTIMEDIA

Because of its bulkiness, multimedia is often best stored at a few centralized sites and retrieved from there. That can entail logistical problems since video and audio in particular need to be delivered at a certain minimum speed to be viewable or listenable (Smith, Mohan, & Li, 1999). Video or audio can be fully downloaded in advance of playing, but this entails a time delay and most citizens prefer real-time delivery (streaming). Important applications with streaming are being accomplished including video meetings, video medicine, distance learning, multimedia mail, and interactive television. Streaming is simplified if it is delivered by one-way broadcast, and this works well for standardized content such as training materials. Traditional technology like television can also be effective in the streaming of government media (Morisse, Cortes, & Luling, 1999) but requires citizens to access it at a particular time. Another alternative is to supply

citizens with an optical disk (CD-ROM or DVD) containing the media.

The biggest challenge with streaming is ensuring adequate bandwidth (rate of data transmission). A single MPEG-1 compressed video of standard television-picture quality needs around 2 megabits per second (though videoconferencing and speeches can be adequate with less), and music audio requires 1 megabit per second. Standard (ISDN) telephone lines provide 0.064 megabits per second, inadequate for both. T-1, T-2, and other lines can improve this to theoretically 1.5 megabits per second, but that is still inadequate for video. Digital subscriber lines using cable-television technology can provide higher bandwidths using network technologies such as ATM, but even those can be pressed to produce real-time video. Data-compression techniques can reduce bandwidth somewhat; typical maximum compression ratios range from 2:1 for audio to 20:1 for images and 50:1 for video. Other tricks with noncritical video are to periodically skip frames or decrease the size of the images.

Transmission bandwidth is also bounded by the delivery rate of the media from an archive. Live video may be able to bypass storage and go directly onto the network. But in general, multimedia data must be archived in blocks for efficient memory management, though the blocks can be larger than those typical for text. Magnetic tape and optical disks are less flexible in manipulating blocks than magnetic disks, so the latter is preferable for multimedia. But it does take time for a disk head to go between blocks, so successive blocks can be put on different disks so that a block from one disk can be transmitted while the other block is being readied (striping).

Besides bandwidth limits, networks can also have transmission delays (latency), which affects real-time interactive applications like videoconferencing. Delays can be minimized by good network routing (Ali & Ghafoor, 2000; Gao, Zhang, & Towsley, 2003). Using different paths to relay different parts of multimedia data from source to destination can reduce the effect of any one bottleneck. If data loss is especially important to avoid, redundant data can be sent over the multiple paths. But much video playback can tolerate occasional data loss.

Another transmission issue is the evenness of the arrival of multimedia data at a destination site (burstiness or jitter) since unevenness can cause unacceptable starts and stops in audio or video. This can happen when other network traffic suddenly increases or decreases significantly. Usually, video delays cannot exceed 0.1 seconds and music-audio delays 0.0001 seconds, so this is a key quality-of-service issue. Caching of data in storage buffers at the delivery site reduces the problem, but effective multimedia buffers must be big. Transmission by multiple routes will also help.

Multimedia delivery is still more difficult when the destination device is a small handheld one since these are limited in memory, processor speed, and networking capabilities. Although multimedia is better displayed on conventional computer hardware, many users prefer such small devices to access the Internet while engaged in other activities. Then streaming is necessary and must be done with significant bandwidth and screen-size limits. Managing the display of information on handheld devices is called content repurposing and is an active area of research (Alwan et al, 1996; Singh, 2004).

Other important technical issues in streaming include the following (Jadav & Choudhary, 1995).

- System architectures should be chosen for fast input and output; parallel ports are desirable.
- Star and fully connected network topologies are desirable. That may only be feasible with local networks for many applications.
- Switches should be preferred to routers on network connections since the routers have lower bandwidths and higher delays.

- Experimentation with the packet size for multimedia data may improve performance since the best size is hard to predict.
- Caching of frequently used data can help efficiency since some media objects will be much more popular than others.

Thus, without careful design there can be serious problems in multimedia delivery. These problems can be negotiated between senders and receivers, either beforehand or at the time of transmission. Generally speaking, worst-case or deterministic metrics for quality of service are more important than average-case or statistical ones for real-time multimedia since users have limits in unacceptable speed, delay, or jitter.

ARCHIVING OF MULTIMEDIA

Governments must archive many important records, and this includes multimedia information. The size of media objects necessitates high storage costs and slow access. While the costs of storage media continue to decrease, now more data is being created in the first place.

A problem for archiving is the diversity of storage devices and media formats. New ones arise continually, so archiving requires either archiving the hardware and software that can read the stored media even when the hardware, software, and formats are no longer being used for new media, or else periodically recopying the data into new devices and formats (Friedlander, 2002). For instance, the Library of Congress of the United States still has audio stored on wire media, a technology long obsolete. Video may be a particular problem in the future as there are several competing formats today as well as an ongoing shift to high-definition images. Unfortunately, digital media is different from old books in that it can be virtually undecipherable without the right hardware and software to read it. So governments must continually invest to support their media archives.

Another problem for digital government is to decide what to archive (Liu & Hseng, 2004). Legal requirements may specify particular archiving, but governments have a responsibility to anticipate future data needs as well. Copyright issues can actually simplify as media ages and enters the public domain. But when money for archiving is limited, conflicting interests within the public may disagree as to what information to keep, and politics may be needed to resolve this.

FUTURE TRENDS

The increasing speed of computers and networks and the decreasing cost of digital storage will enable increased use of multimedia in computer systems in the future. This will enable governments to store and offer increasing amounts of multimedia data for their citizens. Media like video of public meetings, census maps, and graphics documenting government practices will become routinely available so that all citizens can access them without needing to be physically present at government facilities. The main challenges are indexing all these media so citizens can find them, and delivering them (particularly video) across a network fast enough to be useful. Speed and cost improvements alone will not solve all the technical problems as other issues discussed above must be addressed, too. It will take a number of years to reach levels of adequate government media service even in technologically advanced countries.

CONCLUSION

Multimedia is a natural way for people to communicate with computers, more natural than text, and should become an increasingly common mode for people to learn about and participate in

their governments. Good planning is necessary, however, because the data sizes of multimedia objects can be significantly larger than those of text data. This means that media delivery can be unacceptably slow or uneven with current technology, and this limits what can be offered to citizens. Nonetheless, the technology to support media access is improving, and governments will be able to exploit this.

KEY TERMS

Bandwidth: Amount of data (measured in bits per second) that can be transmitted across a network.

Broadcast: Transmission of some data in one direction only to many recipients.

Caption: Text describing a media object.

Data Compression: Transforming of data so that they require fewer bits to store.

Groupware: Software to support collaborative work between remotely located people.

Jitter: Unevenness in the transmission of data, an important problem for streaming video.

Media Search Engine: A Web search engine designed to find media (usually images) on the Web.

Metadata: Information describing another data object such as its size or caption.

Multimedia: Data that include images, audio, video, or software.

Quality of Service: The quality of data transmission across a computer network as a composite of several factors.

Streaming: Video or audio sent in real time from a source, thereby reducing storage needs.

Chapter 1.3
Core Principals of Educational Multimedia

Geraldine Torrisi-Steele
Griffith University, Australia

INTRODUCTION

The notion of using technology for educational purposes is not new. In fact, it can be traced back to the early 1900s during which school museums were used to distribute portable exhibits. This was the beginning of the visual education movement that persisted throughout the 1930s, as advances in technology such as radio and sound motion pictures continued. The training needs of World War II stimulated serious growth in the audiovisual instruction movement. Instructional television arrived in the 1950s but had little impact, due mainly to the expense of installing and maintaining systems. The advent of computers in the 1950s laid the foundation for CAI (computer assisted instruction) through the 1960s and 1970s. However, it wasn't until the 1980s that computers began to make a major impact on education (Reiser, 2001). Early applications of computer resources included the use of primitive simulation. These early simulations had little graphic capabilities and did little to enhance the learning experience (Munro, 2000).

Since the 1990s, there have been rapid advances in computer technologies in the area of multimedia production tools, delivery, and storage devices. Throughout the 1990s, numerous CD-ROM educational multimedia software was produced and was used in educational settings. More recently, the advent of the World Wide Web (WWW) and associated information and communications technologies (ICT) has opened a vast array of possibilities for the use of multimedia technologies to enrich the learning environment. Today, educational institutions are investing considerable effort and money into the use of multimedia. The use of multimedia technologies in educational institutions is seen as necessary for keeping education relevant to the 21st century (Selwyn & Gordard, 2003).

The term *multimedia* as used in this article refers to any technologies that make possible "the entirely digital delivery of content presented by using an integrated combination of audio, video, images (two-dimensional, three-dimensional) and text," along with the capacity to support user interaction (Torrisi-Steele, 2004,

p. 24). Multimedia encompasses related communications technologies such as e-mail, chat, video-conferencing, and so forth. "The concept of interaction may be conceptualised as occurring along two dimensions: the capacity of the system to allow individual to control the pace of presentation and to make choices about which pathways are followed to move through the content; and the ability of the system to accept input from the user and provide appropriate feedback to that input.… Multimedia may be delivered on computer via CD-ROM, DVD, via the internet or on other devices such as mobile phones and personal digital assistants or any digital device capable of supporting interactive and integrated delivery of digital audio, video, image and text data" (Torrisi-Steele, 2004, p. 24).

The fundamental belief underlying this article is that the goal of implementing multimedia into educational contexts is to exploit the attributes of multimedia technologies in order to support deeper, more meaningful learner-centered learning. Furthermore, if multimedia is integrated effectively into educational contexts, then teaching and learning practice must necessarily be transformed (Torrisi-Steele, 2004). It is intended that this article will serve as a useful starting point for educators beginning to use multimedia. This article attempts to provide an overview of concepts related to the effective application of multimedia technologies to educational contexts. First, constructivist perspective is discussed as the accepted framework for the design of multimedia learning environments. Following this, the characteristics of constructivist multimedia learning environments are noted, and then some important professional development issues are highlighted.

THEORETICAL FOUNDATIONS FOR THE ROLE OF MULTIMEDIA IN EDUCATIONAL CONTEXTS

Traditionally, teaching practices have focused on knowledge acquisition, direct instruction, and the recall of facts and procedures. This approach suited the needs of a society needing "assembly line workers" (Reigeluth, 1999, p. 18). However, in today's knowledge-based society, there is a necessity to emphasize deeper learning that occurs through creative thinking, problem solving, analysis, and evaluation, rather than the simple recall of facts and procedures emphasized in more traditional approaches (Bates, 2000). The advent of multimedia technologies has been heralded by educators as having the capacity to facilitate the required shift away from traditional teaching practices in order to innovate and improve on traditional practices (LeFoe, 1998; Relan & Gillani, 1997). Theoretically, the shift away from traditional teaching practices is conceptualized as a shift from a teacher-centered instructivist perspective to a learner-centered constructivist perspective on teaching and learning.

The constructivist perspective is widely accepted as the framework for design of educational multimedia applications (Strommen, 1999). The constructivist perspective describes a "theory of development whereby learners build their own knowledge by constructing mental models, or schemas, based on their own experiences" (Tse-Kian, 2003, p. 295). The constructivist view embodies notions that are in direct opposition to the traditional instructivist teaching methods that have been used in educational institutions for decades (see Table 1).

Expanding on Table 1, learning environments designed on constructivist principles tend to result in open-ended learning environments in which:

- Learners have different preferences of learning styles, cognitive abilities, and prior knowledge; they construct knowledge

Table 1. Key principles of the constructivist view of teaching and learning vs. key principles of the instructivist view of teaching and learning

CONSTRUCTIVIST	INSTRUCTIVIST
• learner-centered perspective: the learner is the focus of the learning environment – learners as individuals	• teacher-centered perspective: the teacher is focus of the learning environment- group learning
• encourages student independence in learning	• encourages student dependence on teacher
• teacher as facilitator that acts as a guide	• teacher as instructor
• learner and facilitator engage in a collaborative learning experience	• teacher in control of learning and in position of power over learner
• learners actively constructing knowledge in their own individual manner	• learners passively acquiring knowledge from the instructor
• Process of knowledge acquisition is important - how are learners interacting with the learning environment?	• acquisition of content and factual knowledge is key objective of learning episode
• curriculum design as development of knowledge spaces which allow active exploration by the learner	• curriculum design as goal oriented, strictly structured and ordered knowledge transmission
• Higher order thinking skills emphasized, creative thinking, problem solving, evaluation, synthesis	• behavioral objectives focusing on recall of facts and procedures, surface learning
• Open-ended learning environments (**OELE**)	• **directed instruction**

in individual ways by choosing their own pathways. Learning is affected by its contexts as well as the beliefs and attitudes of the learner;

- Optimal learning occurs when learners are active learners (e.g., learn by doing and learn by discovery;
- Learning is a process of construction whereby learners build knowledge through a process of scaffolding. Scaffolding is the process whereby learners link new knowledge with existing knowledge;
- Knowledge construction is facilitated through authentic problem-solving experiences;

- The process of learning is just as important as learning outcomes. Learners are encouraged to "articulate what they are doing in the environment and reasons for their actions" (Jonassen, 1999, p. 217).

Multimedia, by virtue of its capacity f or interactivity, media integration, and communication, can be easily implemented as a tool for information gathering, communication, and knowledge construction. Multimedia lends itself well to the "creation and maintenance of learning environments which scaffold the personal and social construction of knowledge" (Richards & Nason, 1999). It is worth noting that the interactivity attribute of multimedia is considered extremely important from a constructivist perspective. Interactivity in terms of navigation allows learners to take responsibility for the pathways they follow in following learning goals. This supports the constructivist principles of personal construction of knowledge, learning by discovery, and emphasis on process and learner control. Interactivity in terms of feedback to user input into the system (e.g., responses to quizzes, etc.) allows for guided support of the learner. This also is congruent with constructivist principles of instruction as facilitation and also consistent with the notion of scaffolding, whereby learners are encouraged to link new to existing knowledge.

Using the constructivist views as a foundation, the key potentials of multimedia to facilitate constructivist learning are summarized by Kramer and Schmidt (2001) as:

- Cognitive flexibility through different accesses for the same topic;
- Multi-modal presentations to assist understanding, especially for learners with differing learning styles;
- "Flexible navigation" to allow learners to explore "networked information at their own pace" and to provide rigid guidance, if required;
- "Interaction facilities provide learners with opportunities for experimentation, context-dependent feedback, and constructive problem solving";
- Asynchronous and synchronous communication and collaboration facilities to bridge geographical distances; and
- Virtual laboratories and environments can offer near authentic situations for experimentation and problem solving.

THE EFFECTIVE IMPLEMENTATION OF MULTIMEDIA IN EDUCATIONAL CONTEXTS

Instructional Design Principles

Founded on constructivist principles, Savery and Duffy (1996) propose eight constructivist principles useful for guiding the instructional design of multimedia learning environments:

- Anchor all learning activities to a larger task or problem.
- Support learning in developing ownership for the overall problem or task.
- Design an authentic task.
- Design the tasks and learning environment to reflect the complexity of the environment that students should be able to function in at the end of learning.
- Give the learner ownership of the process to develop a solution.
- Design the learning environment to support and challenge the learner's thinking.
- Encourage testing ideas against alternative views and contexts.
- Provide opportunity for and support reflection on both the content learned and the process itself.

Along similar lines, Jonassen (1994) summarizes the basic tenets of the constructivist-guided

instructional design models to develop learning environments that:

- Provide multiple representations of reality;
- Represent the natural complexity of the real world;
- Focus on knowledge construction, not reproduction;
- Present authentic tasks (contextualizing rather than abstracting instruction);
- Provide real-world, case-based learning environments rather than pre-determined instructional sequences;
- Foster reflective practice;
- Enable context-dependent and content-dependent knowledge construction; and support collaborative construction of knowledge through social negotiation, not competition among learners for recognition.

Professional Development Issues

While multimedia is perceived as having the potential to reshape teaching practice, oftentimes the attributes of multimedia technologies are not exploited effectively in order to maximize and create new learning opportunities, resulting in little impact on the learning environment. At the crux of this issue is the failure of educators to effectively integrate the multimedia technologies into the learning context.

[S]imply thinking up clever ways to use computers in traditional courses [relegates] technology to a secondary, supplemental role that fails to capitalise on its most potent strengths. (Strommen, 1999, p. 2)

The use of information technology has the potential to radically change what happens in higher education...every tutor who uses it in more than a superficial way will need to re-examine his or her approach to teaching and learning and adopt new strategies. (Tearle, Dillon, & Davis, 1999, p. 10)

Two key principles should underlie professional development efforts aimed at facilitating the effective integration of technology in such a way so as to produce positive innovative changes in practice:

Principle 1: Transformation in Practice as an Evolutionary Process

Transformation of practice through the integration of multimedia is a process occurring over time that is best conceptualized perhaps by the continuum of stages of instructional evolution presented by Sandholtz, Ringstaff, and Dwyer (1997):

- **Stage one:** Entry point for technology use where there is an awareness of possibilities, but the technology does not significantly impact on practice.
- **Stage two:** Adaptation stage where there is some evidence of integrating technology into existing practice
- **Stage three:** Transformation stage where the technology is a catalyst for significant changes in practice.

The idea of progressive technology adoption is supported by others. For example, Goddard (2002) recognizes five stages of progression:

- **Knowledge stage:** Awareness of technology existence.
- **Persuasion stage:** Technology as support for traditional productivity rather than curriculum related.
- **Decision stage:** Acceptance or rejection of technology for curriculum use (acceptance leading to supplemental uses).
- **Implementation stage:** Recognition that technology can help achieve some curriculum goals.

- **Confirmation stage:** Use of technology leads to redefinition of learning environment—true integration leading to change.

The recognition that technology integration is an evolutionary process precipitates the second key principle that should underlie professional development programs—reflective practice.

Principle 2: Transformation is Necessarily Fueled by Reflective Practice

A lack of reflection often leads to perpetuation of traditional teaching methods that may be inappropriate and thus fail to bring about "high quality student learning" (Ballantyne, Bain & Packer, 1999, p. 237). It is important that professional development programs focus on sustained reflection on practice from the beginning of endeavors in multimedia materials development through completion stages, followed by debriefing and further reflection feedback into a cycle of continuous evolution of thought and practice. The need for educators to reflect on their practice in order to facilitate effective and transformative integration of multimedia technologies cannot be understated.

In addition to these two principles, the following considerations for professional development programs, arising from the authors' investigation into the training needs for educators developing multimedia materials, are also important:

- The knowledge-delivery view of online technologies must be challenged, as it merely replicates teacher-centered models of knowledge transmission and has little value in reshaping practice;
- Empathising with and addressing concerns that arise from educators' attempts at innovation through technology;
- Equipping educators with knowledge about the potential of the new technologies (i.e., online) must occur within the context of the total curriculum rather than in isolation of the academic's curriculum needs;
- Fostering a team-orientated, collaborative, and supportive approach to online materials production;
- Providing opportunities for developing basic computer competencies necessary for developing confidence in using technology as a normal part of teaching activities.

LOOKING TO THE FUTURE

Undeniably, rapid changes in technologies available for implementation in learning contexts will persist. There is no doubt that emerging technologies will offer a greater array of possibilities for enhancing learning. Simply implementing new technologies in ways that replicate traditional teaching strategies is counterproductive. Thus, there is an urgent and continuing need for ongoing research into how to best exploit the attributes of emerging technologies to further enhance the quality of teaching and learning environments so as to facilitate development of lifelong learners, who are adequately equipped to participate in society.

CONCLUSION

This article has reviewed core principles of the constructivist view of learning, the accepted framework for guiding the design of technology-based learning environments. Special note was made of the importance of interactivity to support constructivist principles. Design guidelines based on constructivist principles also were noted. Finally, the importance of professional development for educators that focuses on reflective practice and evolutionary approach to practice transformation was discussed. In implementing future technologies in educational contexts, the

goal must remain to improve the quality of teaching and learning.

KEY TERMS

Active Learning: A key concept within the constructivist perspective on learning that perceives learners as mentally active in seeking to make meaning.

Constructivist Perspective: A perspective on learning that places emphasis on learners as building their own internal and individual representation of knowledge.

Directed Instruction: A learning environment characterized by directed instruction is one in which the emphasis is on "external engineering" (by the teacher) of "what is to be learned" as well as strategies for "how it will be learned" (Hannafin, Land & Oliver, 1999, p. 122).

Instructivist Perspective: A perspective on learning that places emphasis on the teacher in the role of an instructor that is in control of what is to be learned and how it is to be learned. The learner is the passive recipient of knowledge. Often referred to as teacher-centered learning environment.

Interactivity: The ability of a multimedia system to respond to user input. The interactivity element of multimedia is considered of central importance from the point of view that it facilitates the active knowledge construction by enabling learners to make decisions about pathways they will follow through content.

Multimedia: The entirely digital delivery of content presented by using an integrated combination of audio, video, images (two-dimensional, three-dimensional) and text, along with the capacity to support user interaction (Torrisi-Steele, 2004).

OELE: Multimedia learning environments based on constructivist principles tend to be open-ended learning environments (OELEs). OELEs are open-ended in that they allow the individual learner some degree of control in establishing learning goals and/or pathways chosen to achieve learning.

Reflective Practice: Refers to the notion that educators need to think continuously about and evaluate the effectiveness of the strategies and learning environment designs they are using.

Chapter 1.4
Multimedia Instruction

Lorna Uden
Staffordshire University, UK

INTRODUCTION

Multimedia technology is increasingly being used as a vehicle to deliver instruction.

The terms "hypermedia" and "multimedia" are often used interchangeably. However, a distinction is sometimes made: Not all multimedia applications are necessarily hypermedia. A network representation of information is one of the defining characteristics of hypermedia. An instance of hypermedia consists of pieces of information connected in an arbitrary manner to form a network of references (Begoray, 1990). In this chapter, the terms will be used synonymously. There are many benefits for using multimedia for instruction.

Studies have shown that computer-based multimedia can help people learn more information better than traditional classroom lectures (Bagui, 1998). Several factors have been attributed to the success of multimedia in helping people to learn. First, there is a parallel between multimedia and the 'natural' way people learn, as explained by the Information Processing Theory (Gagné, Briggs & Wager, 1988). The similarities between the structure of multimedia and the information processing theory account for a large part of the success of learning with multimedia.

Second, information in computer-based multimedia is presented in a non-linear, hypermedia format. The nature of hypermedia allows learners to view things from different perspectives. Third, computer-based multimedia is more interactive than traditional classroom lectures. Interacting appears to have a strong positive effect on learning (Najjar, 1996). Fourth, another feature of multimedia-based learning is that of flexibility. There is empirical evidence (Najjar, 1996) that interactive multimedia information helps people learn.

A large number of presentation guidelines have been reported for educational multimedia (Kozma, 1991; Park & Hannafin, 1994) that advise on selecting certain media for different types of content and learning goals. Investigation by Schaife and Rogers (1996) revealed that many of these products exhibit poor usability and are ineffective in learning. Multimedia design is currently created by intuition (Sutcliffe, 1997). Given the complexity of multimedia interaction,

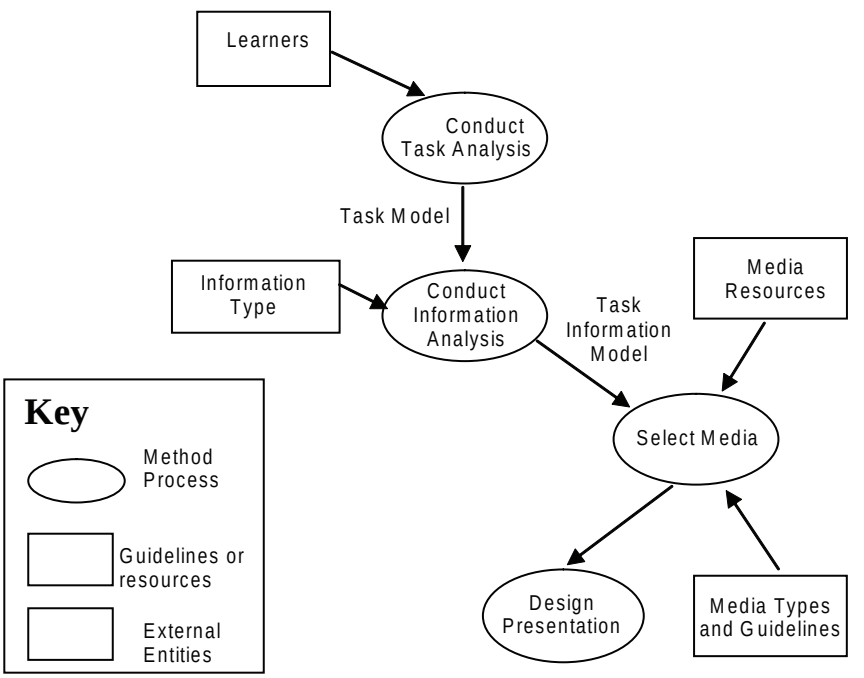
it is unlikely that the craft-style approach will produce effective interfaces. A methodical approach to multimedia interface design is needed. Guidelines are required to cover selection of media resources for representing different types of information and presentation design. These guidelines must address the key issues of selective attention, persistence of information, concurrency and preventing information overload. Multimedia provides designers with many opportunities to increase the richness of the learner interface, but with richness comes the penalty that interfaces can become overcrowded with too much information. Using multimedia does not ensure that information is conveyed in a comprehensive manner. Careful design is required to ensure that the medium matches the message and that important information is delivered effectively. To date, there are few methods available that give detailed guidelines to help designers choose the most appropriate medium based on the information types required. Subsequent sections of this article describe a method known as Multimedia Instructional Design Method (MIDM), based on the Sutcliffe and Faraday method (1994) that can be used to help novice designers to develop multimedia instruction.

MULTIMEDIA INSTRUCTION DESIGN METHOD

The method developed is based on the work of Sutcliffe and Faraday (1994). It consists of four main stages: task analysis, information analysis, media selection and presentation, as shown in Figure 1.

The method consists of design principles based on cognitive psychology, media selection guidelines that utilise definition of information and media types, validation guidelines for media combination and techniques for directing the learners' attention in multimedia sequences.

Figure 1. Overview of the method



The first step is the creation of a task model incorporating specification of the content information requirements. A resource model describing the information media available to the designer then follows this. The method advises on selecting appropriate media for the information needs and scripting a coherent presentation for a task context.

The next design step is to direct the learner's attention to extract the required information from a given presentation and focus on the correct level of detail. This forces designers to be aware of the cognitive issues underlying a multimedia presentation, such as selective attention, persistence of information, concurrency and limited cognitive resources, such as working memory.

Step 1: Conduct Task Analysis

The method starts with a standard task analysis using one of the instructional task analysis methods. Both hierarchical task analysis and information-passing task analysis methods can be used. In addition, a learner analysis would also be conducted. The task analysis would have produced a hierarchy of goals composed of sub-goals, which in turn contain procedures, actions and objects.

Step 2: Conduct Information Analysis

The task analysis does not explicitly state what information is required for each task step, so an information analysis is needed. The main objective of information analysis is to specify what type of information is required during a task, called the task information model. To form the task information model, the initial goal hierarchy from the task analysis model is elaborated on by attaching information types that specify the content to be communicated to the learner. The resulting model should allow the designer to answer the question, "What information content does the learner need for this task sub-goal or input/output interaction?" A set of amodal information types is required to characterise lesson needs. Information types are used to specify the message to be delivered in a multimedia application and are operated on by mapping rules that select the appropriate media types. The information types are similar to those found in many tasks or data models (e.g., actions,

Table 1. Type of information

Abstract information	Facts or objects that do not have a physical existence; e.g., human knowledge, facts, concepts, plans.
Causation	Description of the cause and effect of an event, including a sequence of events that describe causation; e.g., heat causing water to boil, behaviour of an algorithm that results in a desired goal.
Composition	The aggregation or assembly of an object, whole-part relationships; e.g., components of a car engine, parts of a computer processor, memory, motherboard.
Description	Facts that describe an object, entity or agent; e.g., red apples, texture of stone.
States	Descriptions that remain constant for part of the world, objects or agent world, during a period of time; e.g., a person is sleeping.
Physical	Objects or agents that have a physical existence; e.g., chair, table.
Visio-spatial	Visual attributes of objects, structures, pathways, spatial distribution, location, size, shape; e.g., layout of furniture in a room, direction to bus station, shape of a mountain.

objects, procedures). Task actions may require operational information (the nature of the action to be performed), temporal information (the time course of the action to be performed) or spatial information (the physical nature of the action). Task objects may require descriptive information (detail of the object) or spatial information (the location of the object). Information types are amodal or conceptual descriptions of information components that elaborate the content definition. Table 1 describes some of the information types that can be used.

Information types are used to help refine descriptions of the necessary content. The motivation is to provide informal categories that help assess what type of information is required to support user and system tasks. Information can be broadly divided into static data about objects and dynamic data describing actions, events and changes in the environment.

A media resource analysis is also carried out in this stage. This section describes media resources available to the application for presentation. Media resources considered here are linguistic (text and speech), still image (photographs, drawings) and moving image (animated diagrams, video). Classification is based on the psychological properties of the representation rather than the physical nature of the medium (e.g., digital or analogue encoding in video). Table 2 lists the media type definitions and examples. These definitions are combined to describe any specific medium, so speech is classed as an audio, linguistic medium, while a cartoon is classified as a non-realistic (designed) moving image. Each media resource will contain one or more information types: temporal information, spatial information, operational information or descriptive information.

Having defined the resources available for presentation, the information task model and the information requirements for the task, we now have to decide which media types to use for the task's information needs. To do this, the task model is first elaborated on by attaching dialogue acts to specify the desired effect of presenting the information. Dialogue acts are used in explanation systems (Mann & Thompson, 1988). These are added to the task model to designate the

Table 2. Media type definitions and examples

Media Type	Description	Example
Non-realistic	content created by human action rather than being captured from the real world.	Diagrams, graphs, cartoons.
Realistic	content perceived by users to have been captured form the natural world rather than being explicitly designed.	Natural sounds, photographic images, film showing people and natural scenes.
Audio	any medium received by the audio channel (hearing), sounds	Dog barking, music, traffic noise, speech.
Linguistic	text, spoken language and symbols interpreted in linguistic terms.	Alphanumeric text, symbols and signs.
Moving image	visual media delivered at a continuous rate.	Video, film, animated diagrams and simulations.
Still image	visual media that are not presented continuously.	Photographs, drawings, graphs.

Table 3. Dialogue acts and their communicative effects

Act Type	Act Name	Communicative Effect
Subject-informative	Enable	Communicate actions to achieve a task sub-goal.
	Result	Give information about the outcome of a task sub-goal.
	Cause	Give information concerning the causality of a task sub-goal.
	Inform	Display information as-is.
Subject-organising	Sequence	Specify a succession of linked steps.
	Summary	Provide overview of task sub-goal(s).
	Condition	A particular task sub-goal is a pre-condition.
Presentational	Locate	Draw attention to an information type.
	Foreground	Give further detail of an information type.
	Background	Give content information.
	Emphasise	Make an information type prominent.

communicative effect to be achieved, answering the questions: "What information does the user need for the goal?" and "How should the user's attention be drawn to important information?" These questions can be answered by splitting the dialogue acts into subject and presentation based acts (see Table 3).

Subject-based acts elaborate on information types according to the procedure and action-level detail in the task model. Subject acts are subdivided into subject-informative acts (which define information needs according to stages of task procedure) and subject-organising acts (which control the sequence of presentation and hence organise the subject-informative acts).

Presentational acts are used on media resources to draw the user's attention to particular information type(s), thereby supporting the subject act. Dialogue acts are linked to the task model by "walkthrough," asking, "What information or explanation is required at this step?"

At the start of each task procedure, describe its order (sequence), the goal (summary) and any preconditions upon it being performed (conditions). Information may be necessary as input for task actions (enable), followed by display of results of action (result). The user's needs could be to "Foreground" the information type (e.g., draw attention to a property of object associated with a particular task action) or to present an information type at a higher, more general level such as may be necessary at the start of a task (summary), or to draw attention explicitly to important information (emphasise).

Step 3: Select Media

The incorporation of media in a multimedia instructional application requires design principles based on modality theory. Modality is the medium used; hence, it is the mode of representation to present the required message. There are thousands of modalities, both input and output, that can be incorporated into interface designs (Bernsen, 1994). Selecting an optimal unimodal modality from this vast array of alternatives is difficult, due to each modality having a set of information representation characteristics, making it good for

the representation of certain information types and bad for others. The combination of two or more of these modalities exacerbates the problem as, when several modalities (both input and/or output) are involved, media interference needs to be taken into consideration.

According to Bernsen (1994), Modality Theory addresses the following general information-mapping problem: "Given any particular set of information which needs to be exchanged between the user and system during task performance in context, identify the input/output modalities which constitute an optimal solution to the representation and exchange of the information" (p. 348). Current multimedia research attempts to address modality design by creating methods that remove the ad hoc nature of solutions by providing theoretical frameworks for developers to follow. The problem these methods must solve, if viewed in the most basic terms, can be regarded as the information-mapping problem, which requires that a mapping exist between task requirements and a set of usable modalities.

Several issues need to be addressed when designing multimedia applications. When selecting a medium for use, we should select one that is specifically suited/adapted to represent the information requirements of the concept; that is, to describe the appearance of a person, a photograph should be used in preference to a text extract, as it provides a clearer description. This involves the use of theory on media usage, because the aim is to select a medium that best addresses the information requirements of the concept to be represented. The way to do this is to use media selection rules derived from modality theory. Another issue to be considered is how can optimal media or combinations be selected? These issues highlight the need for theoretical methods. Combining methods with media theory enables us to derive principles that can guide us toward making optimal media and combination decisions.

Media Selection Guidelines

When different media resources are available, we need to choose the medium to deliver the information needed. Task and user characteristics influence media choice. For instance, verbal media are more appropriate to language-based and logical reasoning tasks. Conversely, visual media are suitable for spatial tasks, including moving, positioning and orienting objects. Selection guidelines are based on the information types required for the subject dialogue act and task step type. The information types used with the media selection guidelines are shown in Table 4.

The guidelines may be used in multiple passes. For example, when a procedure for explaining a physical task is required, we can first call realistic image media, then a series of images and text. Guidelines that differentiate physical from abstract information are used first, followed by other guidelines.

Having designed the presentation, a set of validation guidelines is applied to the presentation design. The guidelines are derived from psychological and instructional design literature. The following guidelines are adopted from Sutcliffe and Faraday (1994):

1. If visual and verbal modalities are used concurrently, ensure congruent presentation by checking that information on each modality is semantically related.
2. Use text or still images for key messages.
3. Use verbal channel for warning.
4. Multiple attention-gaining devices should be avoided within a single task sub-goal presentation.
5. Do not present different subject matter on separate channels.
6. Use only visual-verbal channels concurrently.
7. Present only one animation or changing still image resource at a time.

Table 4. Overview of media selection preferences and examples

Information types	Preferred Media Selection	Example
Physical	still or moving image	building diagram
Abstract	text or speech	explain sales policy
Descriptive	text or speech	chemical properties
Visio-spatial	realistic media – photograph	person's face
Value	text/tables/numeric lists	pressure reading
Relationships (values)	design images – graphs – charts	histogram of rainfall per month
Procedural	images, text	evacuation instruction
Discrete action	still image	make of coffee
Continuous action m	oving image	manoeuvres while skiing
Events	sound, speech	fire alarm
States	still image, text	photo of weather conditions
Composition	still image, moving image	exploded part diagrams
Causal	moving image, text, speech	video of rainstorm causing flash flood

8. **Beware:** Visual media tend to dominate over verbal—place important messages in visual channel in concurrent visual-verbal presentations.
9. If several information types need to be semantically integrated, then use a common modality, as associations are formed more effectively within than between single semantic systems.

Step 4: Design the Presentation

Sutcliffe (1999) states that presentation design is primarily concerned with visual media, as the user's viewing sequence is unpredictable. The design should make important information salient in both speech and sound. It is important that a designer in multimedia links the thread of a message across several media. Presentation techniques are used to help direct the learner's attention to important information and to specify the desired order of reading or viewing. While the information model defines the high-level presentation order, presentation bar charts are used to plan the sequence and duration of media delivery.

First, the information types are ordered in a "first cut" sequence. The selected media are then added to the bar chart to show which media stream will be played over time. Decisions on timing depend on the content of the media resource; for example, length of a video clip, frame display and rate.

It is important to add focus-control actions to the first-cut presentation script to either make specific information within a medium more salient or to draw the learners' attention to message links between media. The need for focus shifts between information components is identified. Attention marker techniques are selected to implement the desired effect. Things to consider here are:

1. Plan the overall thematic thread of the message through the presentation or dialogue.
2. Draw the learners' attention to important information.
3. Establish a clear reading/viewing sequence.
4. Provide clear links when the theme crosses from one medium to another.

Direct Learner Attention Techniques

When the message is important and cross-referencing is critical, it is important to draw the learners' attention to both the source and destination medium. "Contact point" is used to describe a reference from one medium to another (Sutcliffe, 1999). There are two types of contact point: direct

and indirect. With direct contact points, attention-directing effects are implemented in both source and destination media. Conversely, with indirect contact points, an attention-directing effect is implemented only in the source medium.

Guidelines for Contact Point Uses

1. **Direct contact points for key thematic links:** A direct contact point should be used if the connection between information in two different media is important. For example, speech is used to direct the learners to the object in the image while highlighting the object being spoken about: "Look at the map"; the location of the laboratory is highlighted; or a text caption is revealed with an arrow pointing to the laboratory.
2. **Direct contact points for linked components:** Direct contact points should be used if components in both source and destination media are important and have to be perceived. For example: "Locate fire team in the diagram" (speech track), the team location is highlighted (with arrow).
3. **Indirect contact points:** Indirect contact points are used when the connection between information in two media is necessary, but perception of the destination component is less important. For example: "Look at the diagram," speaking about the object while displaying the image.

This concludes the method stages, which have now produced a detailed and thematically integrated presentation design. The guidelines can be applied either to the specification bar chart before implementation or interactively during a cycle of prototype implementation, evaluation and critiquing.

FUTURE TRENDS

Multimedia development is currently at the stage that software development was 30 years ago. Most applications are developed using an ad hoc approach. There is little understanding of development methodologies, measurement and evaluation technologies, development processes, and application quality and project management. This current approach to developing multimedia is, in many cases, failing to deliver applications that have acceptance quality, especially in terms of information access and usability. According to researchers (Lowe & Hall, 1999), this failure is largely due to a lack of process. As multimedia applications grow in scope and complexity, we need an evolution (or revolution) to occur, similar to that which occurred in software development. Just as the focus in software development shifted from programming to process, the focus with multimedia must shift from the use of specific authoring tools in handcrafting applications to broader process issues that support the development of high-quality, large-scale applications. This includes aspects such as framework, tools and techniques, validation methods and metrics.

Although multimedia development tools are important, as with software tools, they must be used appropriately within an overall development process that gives them a suitable context. Small applications can still be readily handcrafted, but for large applications, and especially those which will evolve over time, we need to adopt a more formal and thorough approach; that is, a "multimedia engineering" approach. Multimedia engineering is the employment of a systematic, disciplined, quantifiable approach to the development, operation and maintenance of multimedia applications. Applying an engineering approach to multimedia development underlines two primary emphases: first, that multimedia development is a process. This process includes more than just media manipulation and presentation creation. It includes analysis of needs, design management,

metrics and maintenance. The second emphasis is the handling and management of information to achieve some desired goal. Hypermedia engineering is the combination of these two emphases—the use of suitable processes in creating multimedia applications effective in managing and utilising information.

CONCLUSION

The design and development of multimedia instructional applications is not trivial. To produce effective multimedia applications, it is necessary that guidelines used must be based on principles of cognitive psychology. The method proposed is, we believe, a first comprehensive multimedia presentation design method. Although many guidelines have been proposed by researchers to direct designers in their multimedia development, none of these researchers have integrated their guidelines into a design method. One criticism that may be levelled against all of these guidelines is that they produce recommendations expert designers would have come up with anyway. This misses the point that methods *are* produced and introduced to help novice designers improve their performance and ensure that they achieve at least an adequate standard.

Evidence produced by Sutcliffe (1997, 1999) has shown that the proposed method did help improve multimedia applications. Our own experience in using the method to develop multimedia instructional applications has been very encouraging. The above method has been used successfully by more than 60 students from the multimedia degree course in our university to develop different multimedia applications. So far, the method has proved useful as a means of exploring the issues involved in multimedia design. The method provides a tool for thought about presentation issues concerning what information is required and when.

However, the guidelines within the method need further usability testing and evaluation of their effectiveness. Many of the guidelines will appear in the forthcoming multimedia user-interface design standard, ISOI 14915. The method, while making no claim to have solved the multimedia interface design problem, has explored the issues that must be addressed in multimedia interface design. The guidelines and the method can, however, be used as sound design advice to help novice designers develop multimedia instruction.

KEY TERMS

Contact Point: Used to describe a reference from one medium to another.

Education Multimedia: The use of multimedia for designing educational software.

Information Type: The description of necessary content in an application.

Modality: The medium used, the mode of representation to present the required message.

Modality Theory: Given any particular set of information that needs to be exchanged between the users and system during task performance in context, identify the input/output modalities that constitute an optimal solution to representation and exchange of the information (Bernsen, 1994).

Multimedia: The use of different media such as text, graphics, audio and video, and others.

Multimedia Engineering: The employment of a systematic, disciplined, quantifiable approach to the development, operation and maintenance of multimedia applications.

Chapter 1.5
Multimedia Technologies in Education

Armando Cirrincione
SDA Bocconi School of Management, Italy

WHAT ARE MULTIMEDIA TECHNOLOGIES

MultiMedia Technologies (MMT) are all that kind of technological tools that make us able to transmit information in a very large meaning, transforming information into knowledge through stimulating the cognitive schemes of learners and leveraging the learning power of human senses. This transformation can acquire several different forms: from digitalized images to virtual reconstructions, from simple text to iper-texts that allow customized, fast, and cheap research within texts; from communications framework like the Web to tools that enhance all our sense, allowing complete educational experiences (Piacente, 2002b).

MMT are composed by two great conceptually different frameworks (Piacente, 2002a):

- **Technological supports, as hardware and software:** all kinds of technological tools such as mother boards, displays, videos, audio tools, databases, communications software and hardware, and so on;
- **Contents:** information and to knowledge transmitted with MMT tools. Information are simply data (such as visiting timetable of museum, cost of tickets, the name of the author of a picture), while knowledge comes from information *elaborated in order to get a goal*. For instance, a complex ipertext about a work of art, where much information is connected in a logical discourse, is knowledge. For the same reason, a virtual reconstruction comes from knowledge about the rebuilt facts.

It's relevant to underline that to some extent technological supports represent a condition and a limit for contents (Wallace, 1995). In other words, content could be expressed just through technological supports, and this means that content has to be made in order to fit for specific technological support and that the limits of a specific technological support are also the limits of its content. For instance the specific architecture of a database represents a limit within which contents have to be recorded and have to be traced. This is also evident thinking about content as a communicative

action: communication is strictly conditioned by the tool we are using.

Essentially, we can distinguish between two areas of application of MMT (Spencer, 2002) in education:

1. Inside the educational institution (schools, museums, libraries), with regard to all tools that foster the value of lessons or visiting during time they takes place. Here we mean "enhancing" as enhancing moments of learning for students or visitors: hypertexts, simulation, virtual cases, virtual reconstructions, active touch-screen, video, and audio tools;
2. In respect of outside the educational institution, this is the case of communication technologies such as Web, software for managing communities, chats, forums, newsgroups, for long-distance sharing materials, and so on. The power of these tools lies on the possibilities to interact and to cooperate in order to effectively create knowledge, since knowledge is a social construct (Nonaka & Konno, 1998; von Foester, 1984; von Glaserfeld, 1984).

Behind these different applications of MMT lies a common database, the heart of the multimedia system (Pearce, 1995). The contents of both applications are contained into the database, and so the way applications can use information recorded into database is strictly conditioned by the architecture of database itself.

DIFFERENT DIMENSIONS OF MMT IN TEACHING AND LEARNING

We can distinguish two broader framework for understanding contributions of MMT to teaching and learning.

The first pattern concerns the place of teaching; while in the past, learning generally required the simultaneous presence of teacher and students for interaction, now it is possible to teach long distance, thanks to MMT.

The second pattern refers to the way people learn; they can be passive or they can interact. The interaction fosters learning process and makes it possible to generate more knowledge in less time.

Teaching on Site and Distance Teaching

Talking about MMT applications in education requires to separate learning on-site and distance learning, although both are called e-learning (electronic learning). E-learning is a way of fostering learning activity using electronic tools based on multimedia technologies (Scardamaglia & Bereiter, 1993).

The first pattern generally uses MMT tools as a support to traditional classroom lessons; the use of videos, images, sounds, and so on can dramatically foster the retention of contents in student's minds (Bereiter, Scardamaglia, Cassels, & Hewitt, 1997).

The second pattern, distance teaching, requires MMT applications for a completely different environment, where students are more involved in managing their commitment. In other words, students in e-learning have to use MMT applications more independently than they are required to do during a lesson on site. Although this difference is not so clear among MMT applications in education, and it is possible to get e-learning tools built as they had to be used during on-site lessons and vice-versa, it is quite important to underline the main feature of e-learning not just as a distant learning but as a more independent and responsible learning (Collins, Brown, & Newman, 1995).

There are two types of distance e-learning: self-paced and leader-led. The first one is referred to the process students access computer-based (CBT) or Web-based (WBT) training materials

at their own pace. Learners select what they wish to learn and decide when they will learn it.

The second one, leader-led e-learning, involves an instructor and learners can access real-time materials (synchronous) via videoconferencing or audio or text messaging, or they can access delayed materials (asynchronous).

Both the cited types of distance learning use performance support tools (PST) that help students in performing a task or in self-evaluating.

Passive and Interactive Learning

The topic of MMT applications in an educational environment suggests distinguishing two general groups of applications referring to required students behaviour: passive or interactive. Passive tools are ones teachers use just to enhance the explanation power of their teaching: videos, sounds, pictures, graphics, and so on. In this case, students do not interact with MMT tools; that means MMT application current contents don't change according to the behaviour of students.

Interactive MMT tools change current contents according to the behaviour of students; students can chose to change contents according with their own interests and levels. Interactive MMT tools use the same pattern as the passive ones, such as videos, sounds, and texts, but they also allow the attainment of special information a single student requires, or they give answers just on demand. For instance, self-evaluation tools are interactive applications. Through interacting, students can foster the value of time they spent in learning, because they can use it more efficiently and effectively.

Interaction is one of the most powerful instruments for learning, since it makes possible active cooperation in order to build knowledge. Knowledge is always a social construct, a sense-making activity (Weick, 1995) that consists in giving meaning to experience. Common sense-making fosters knowledge building thanks to the richness of experiences and meanings people can exchange. Everyone can express his own meaning for an experience, and interacting this meaning can be elaborated and it can be changed until it becomes common knowledge. MMT help this process since they make possible interaction in less time and over long distance.

THE LEARNING PROCESS BEHIND E-LEARNING

Using MMT applications in education allows to foster learning process since there are several evidences that people learn more rapidly and deeply from words, images, animations, and sounds, than from words alone (Mayer, 1989; Mayer and Gallini, 1990). For instance, in the museum sector there is some evidence of the effectiveness of MMT devices too: Economou (1998) found firstly that people spend more time and learn more within a museum environment where there are MMT devices.

The second reason why MMT fosters learning derives from interaction they make possible. MMT allow building a common context of meaning, to socialize individual knowledge, to create a network of exchanges among teacher and learners. This kind of network is more effective when we consider situated knowledge, a kind of knowledge adults require that is quite related to problem-solving.

Children and adults have different pattern of learning, since adults are more autonomous in the learning activity and they also need to refer new knowledge to the old one they possess. E-learning technologies have developed a powerful method in order to respond more effectively and efficiently to the needs of children and adults: the "learning objects" (LO). Learning objects are single, discrete modules of educational contents with a certain goal and target. Every learning object is characterized by content and a teaching method that foster a certain learning tool: intellect, senses (sight, heard, and so on), fantasy,

analogy, metaphor, and so on. In this way, every learner (or every teacher, for children) can choose its own module of knowledge and the learning methods that fit better with his own level and characteristics.

As far as the reason why people learn more with MMT tools, it is useful to consider two different theories about learning: the *information delivery theory* and the *cognitive theory.* The first one stresses teaching as just a delivery of information and it looks at students as just recipients of information.

The second one, the cognitive theory, considers learning as a sense-making activity and teaching as an attempt to foster appropriate cognitive processing in the learner. According to this theory, instructors have to enable and encourage students to actively process information: an important part of active processing is to construct pictorial and verbal representations of the lesson's topics and to mentally connect them. Furthermore, archetypical cognitive processes are based on senses, that means: humans learn immediately with all five senses, elaborating stimuli that come from environment. MTT applications can be seen as virtual reproductions of environment stimuli, and this is another reason why MMT can dramatically fostering learning through leveraging senses.

CONTRIBUTIONS AND EFFECTIVENESS OF MMT IN EDUCATION

MMT allow transferring information with no time and space constraints (Fahy, 1995).

Space constraints refer to those obstacles that arise from costs of transferring from one place to another. For instance, looking at a specific exhibition of a museum, or a school lesson, required to travel to the town where it happens; participating to a specific meeting or lesson that takes place in a museum or a school required to be there; preparing an exhibition required to meet work group daily. MMT allows the transmission of information everywhere very quickly and cheaply, and this can limit the space-constraint; people can visit an exhibition stay at home, just browsing with a computer connected on internet. Scholars can participate to meeting and seminars just connecting to the specific web site of the museum. People who are organizing exhibitions can stay in touch with the Internet, sending to each other their daily work at zero cost.

Time constraint has several dimensions: it refers to the need to catch something just when it takes place. For instance, a lesson requires to be attended when it takes place, or a temporary exhibition requires to be visited during the days it's open and just for the period it will stay in. For the same reason, participating in a seminar needs to be there when it takes place.

But time constraint refers also to the limits people suffer in acquiring knowledge: people can pay attention during a visit just for a limited period of time, and this is a constraint for their capability of learning about what they're looking for during the visiting.

Another dimension of time constraint refers to the problem of rebuilding something that happened in the past; in the museum sector, it is the case of extemporary art (body art, environmental installations, and so on) or the case of an archaeological site, and so on.

MMT help to solve these kinds of problems (Crean, 2002; Dufresne-Tassé, 1995; Sayre, 2002) by making it possible:

- To attend school lessons on the Web, using videostreamer or cd-rom, allowing repetition of the lesson or just one difficult passage of the lesson (solving the problem of decreasing attention over time);
- To socialize the process of sense making, and so to socialized knowledge, creating networks of learners;
- To prepare the visit through a virtual visit to the Web site: this option allows knowing ex-ante what we are going to visit, and

doing so, allows selection of a route more quickly and simply than a printed catalogue. In fact, thanks to iper-text technologies, people can obtain lot of information about a picture just when they want and just as they like. So MMT make it possible to organize information and knowledge about heritage into databases in order to customize the way of approaching cultural products. Recently the Minneapolis Institute of Art has started a new project on Web, projected by its Multimedia department, that allow consumers to get all kind of information to plan a deep organized visit;

- To cheaply create different routes for different kind of visitors (adults, children, researcher, academics, and so on); embodying these routes into high tech tools (PCpalm, LapTop) is cheaper than offering expensive and not so effective guided tours.
- To re-create and record on digital supports something that happened in the past and cannot be renewed. For instance the virtual re-creation of an archaeological site, or the recording of an extemporary performance (so diffuse in contemporary art).

For all the above reasons, MMT enormously reduces time and space constraints, therefore stretching and changing the way of teaching and learning.

KEY TERMS

CBT: Computer based training; training material is delivered using hard support (CDRom, films, and so on) or on site.

Cognitive Theory: Learning as a sense-making activity and teaching as an attempt to foster appropriate cognitive processing in the learner.

E-Learning: A way of fostering learning activity using electronic tools based on multimedia tecnologies.

Information Delivery Theory: Teaching is just a delivery of information and students are just recipients of information.

Leader-Led E-Learning: Electronic learning that involves an instructor and where students can access real-time materials (synchronous) via videoconferencing or audio or text messaging, or they can access delayed materials (asynchronous).

LO: Learning objects; single, discrete modules of educational contents with a certain goal and target, characterized by content and a teaching method that foster a certain learning tool: intellect, senses (sight, heard, and so on), fantasy, analogy, metaphor, and so on.

MMT: Multimedia technologies; all technological tools that make us able to transmit information in a very large meaning, leveraging the learning power of human senses and transforming information into knowledge stimulating the cognitive schemes of learners.

PST: Performance support tools; software that helps students in performing a task or in self-evaluating.

Self Paced E-Learning: Students access computer based (CBT) or Web-based (WBT) training materials at their own pace and so select what they wish to learn and decide when they will learn it.

Space Constraints: All kind of obstacles that arise costs of transferring from a place to another.

Time Constraints: It refers to the need to catch something just when it takes place because time flows.

WBT: Web-based training; training material is delivered using the World Wide Web.

Chapter 1.6
Teaching Computer Graphics and Multimedia:
A Practical Overview

John DiMarco
Long Island University, USA

ABSTRACT

This chapter defines and examines situations, problems, and processes faced by teachers of technology. Based on experience teaching at three colleges with different economic, academic, ethnic, and financial attributes, this chapter provides stable and practical approaches to solving common issues. Each school environment and student population presents different technical and interpersonal challenges. Real experiences involving set up of college laboratories, development of digital curriculum, and creation of accredited programs are highlighted and transferred into tangible strategies. If you are new to teaching digital subjects, this text may help you get started. If you are an experienced teacher, this may bring you a new strategy or perspective. Ultimately, this chapter aims to assist student teachers, experienced teachers, artists, information technologists, and computer scientists in becoming stronger in transferring knowledge and skills in the digital realm. In addition, the chapter hopes to invite scholars and educators to explore teaching computer graphics and multimedia within the context of their own disciplines.

INTRODUCTION

The teaching of technological output requires every student to get value from his or her experiences within the laboratory environment. The coursework and laboratory work that challenges a student should simulate real conditions. Course problems should present both conceptual and technical challenges to students. As a digital design professor, I feel that all "digital teachers" have a great responsibility to students. We must transfer knowledge and skills at the highest levels. We must be thorough in our approaches and precise in our criticisms. We teach what we know and must know what we teach. We must teach using real-world materials and techniques. Although we may have varied control over curriculum directions, we do have control over our

success or over that of our students. We must encourage participation, communication, responsiveness, and critical thinking about design and final output. We must always encourage and never insult. We must facilitate practice — and plenty of it. We must be lifetime learners. We must have a personal technology budget. We must be empathetic toward the problems of the individuals we teach. We must take responsibility for the success of the students in our courses. We must care and commit to excellence.

MOTIVATION AND CONFIDENCE

Clear Your Mind and Prepare for Intense Mental Challenges Ahead

Go into the teaching environment with a clear head and focus on the task at hand. It is nearly impossible to communicate effectively when you have worries or problems on your mind. You can use concentrated breathing right before class to free your mind and body of negative energy. Here's how:

1. Sit down (preferably on the floor or on a comfortable chair)
2. Raise your arms and breath deeply with big inhales and exhales for seven to 10 repetitions
3. Concentrate on only your breathing, repeat raising your arms, and take five deep breaths
4. Relax your mind and empty it of all thoughts
5. Get up slowly and focus on the task at hand
6. Review and talk out your lesson outline before leaving the house
7. Arrive at class a few minutes early — rushing will raise stress levels

Remember that teaching computer classes is a mental workout. It makes your mind move rapidly through a barrage of material. It requires you to take information and present it in a hierarchical structure. That requires clear thinking! Here are some tips to help build confidence and success.

Walk Around the Class Frequently

If possible, make it a point to stand briefly near each student. Doing this generates attentiveness and immediately revives a bored student. Mobility keeps people awake!

It is essential to engage students freely and often. It induces interactive communication and results in illustrating your teaching style as a "hands-on" approach. Stay in tune with student work to nurture revision and improvement. Take pride in the project's success: the student is a product of your guidance and cultivation.

How do you stay mobile? Wear comfortable shoes — you will be on your feet. And make a 10-minute rule. If you are seated for 10 minutes or more, get up and walk around. It will keep you sharp and the class listening and alert.

Avoid Frustration

Frustration is one of the biggest obstacles for computer teachers. You must be able to reverse negative student attitudes. You must be able to deal with people who, at first, do not get it. No matter how much you repeat, they do not understand and cannot execute. Try to refrain from berating foolish questions. Be critical, but kind. Become the nicest person you can be — then get even nicer. Being friendly results in relaxation and comfort for the student. Be friendly, but firm. Expect results and anticipate initial failure. Be ready to console and control the negative situation. This is extremely important in the arts where creativity must flow freely. Whoever said "patience is a virtue" never taught computer-based coursework. Do not crack under pressure. Being a computer

teacher requires the patience of a saint. Why? Because every time you have a class that exceeds one person, you have students who have different levels of knowledge and skills with computers. Unless you are teaching an introductory course in computer basics with a room full of blank slates, you will have some students who are more knowledgeable than others. Students may walk into class who have never have touched a computer. In that same class, there may be students who have used computers at home, at school, at work, or in prior training and coursework. You may have a disruptive student or an extra-experienced one who wants to stump the teacher with outlandish or unrelated personal equipment questions that cause class flow to be halted. In the classroom, your brain will be torn in many directions. Do not give up. Stay with it.

Remember Who Controls the Class — You Do!

You control the class, the class does not control you. Therefore, you should set a pace appropriate for your teaching speed — not appropriate to the levels of one or two students. Do not try to cover an abundance of material to satisfy one advanced student. You will end up losing the rest of the class. Let the student explore advanced techniques on their own time or during individualized help sessions with you. Do not lower the goals of the class to cater to one student. We work in a competitive world where computer art and multimedia may not be for every student. Let students understand the responsibilities involved in learning. Both the teacher and student are responsible for success. Without mutual effort, respect, and extensive communication learning will be retarded. Allow a lagging student to work under less intensive criteria; in an academic setting, however, grade accordingly. Sometimes it is best to allow an advanced student to explore new concepts and techniques. Encourage the right students to accelerate or to slow down while keeping the entire class working on the same project at the same pace. This seems like an impossible equilibrium, but try to achieve it. This helps when demonstrating techniques. It helps eliminate premature and old questions.

STUDENT INTERACTION

Motivate Students by Relating Hard Work to Tangible Reward, Not to Academic Failure

Be a coach. Install a winning attitude in every student! Make your class a win-win situation for all students. Let them know that the efforts they put in during class sessions will reap rewards later in their careers. Equate effort to success. Learning computer graphics and multimedia requires a concerted effort toward success. This must include diligent work inside and outside of the classroom and the computer lab. It requires a commitment to lifelong learning and the expansion of skills that occur regularly throughout one's career. Students have to buy into the fact that you are not just their teacher, but also an expert and a valuable resource for them. They have to trust your abilities and they have to share a common goal with you — their success. I believe that a teacher on the college level should try to avoid threatening students with bad grades; rather, make students aware that their grades rely upon success in the course and the projects assigned. Students' success is directly related to effort inside and outside the classroom. Here is my philosophy — I share these thoughts with my students on the first day of each new course:

To learn our craft, we must practice. Practice takes the form of projects. Projects must be completed to succeed in the courses. Completed, well-done projects in our portfolios and backgrounds help us get new projects and jobs. Projects portray our skills, abilities, and experiences. Make your

portfolio scream of completed projects and you will succeed in getting the opportunities you want.

Determine "Can't Do Students" from "Won't Do Students"

Throughout my career, different types of students have challenged me in valuable ways. I have had to learn how to guide them to meeting goals. I categorize notably challenging students in two ways: "can't do students" and "won't do students".

The reasons behind both types of students may be abundant. However, I have found that there are general consistencies between each type. Determining student type and motivation will help you in your goals to help these students succeed in the course, and inevitably to build confidence, skills, knowledge, and work.

"Can't Do Students"

- May have personal problems that are affecting class involvement (missing class for work or illness)
- May not have the time to devote to practice and/or to continued learning
- May not have the resources (lacking a computer at home or the proper software)
- May lack prerequisite skills
- May have a learning disability

"Won't Do Students"

- Put obstacles first and success last
- Always have a list of excuses for not practicing or completing projects
- Battle tooth and nail before joining the pace of the class
- Ask meaningless and obscure questions to help interrupt the flow of the class
- Venture off on their own, not following class procedures and lectures
- May feel they have superior knowledge or experience over the instructor and feel the class is a waste of time for them

Sound familiar? If you have taught computer graphics, you may have encountered these challenging students. We will explore how to make them successful.

Talk to Students and Give Out Initial Assignments to Discover Who is a "Can't Do" or a "Won't Do" Student

A little conversation and some simple questions will go a long way when trying to determine "can't do" students from "won't do" students". I want to learn about my students so I can identify potential highlights and possible problems.

Initially, get to know your student's approaches to his or her own career. What do they plan to do when they graduate? What medium and technology are they most interested in? Ask about prior classes, teachers, outside experience, and determine their genuine interest in the subject. If enthusiasm is low or if the student begins to complain about a former teacher, do not embark on the past obstacles — instead, help become a catalyst for change. Reassure the student that you are committed to their success in this course. Explain that with cooperation, trust, and collaboration, everyone wins. Let the student know that you have the confidence that they will succeed. Always avoid negative comments or confrontation.

An effective method to begin to identify certain student types is to assign a simple homework problem that involves brainstorming on paper. This can be applied to projects including database development, programming, graphic design, multimedia, web design, and video production. I usually make each student begin to write out concepts, metaphors, interaction, messages, and prospective images for the term projects. I require everyone to do it. Those students who do not complete the assignment can be assumed to be possible "won't do" students and will require extra encouragement and more one-on-one time during the learning process. You must continue to work with "won't do" students to help facilitate

involvement. Sometimes "won't do" students will require extra attention and extended feedback on projects to continue valid participation.

When you encounter "won't do" students who insist the projects are below their expectations or abilities, allow them to develop their own approaches. However, specify that they are subject to your approval. This will allow you to monitor the situation to insure the proper focus is maintained. Nevertheless, it will also allow the students to explore new and advanced territory. The result could be extraordinary work.

"Can't do" students need extreme focus to succeed in the digital realm. They will be identified during the first or second project. To help them succeed, practice time must be multiplied, hands-on instruction should be increased and, in extreme cases, students may need to be asked to explore prerequisite courses, possibly more than once. Because "can't do" students often require extra time to complete projects, this will inevitably disrupt the flow of the course during the term. Try to keep all of the students on schedule. Encourage and assist slower students to catch up by increasing practice time and simplifying project approaches and, perhaps, possibly criteria.

Develop an Approach for Each Type of Student: New, Experienced, Young, and Older

Embrace the new challenge, understand it, and conquer it. Your student populations will be a collaboration of diverse personalities, backgrounds, skill sets, dispositions, and problems. We have to embrace this fact and figure out how to cater to everyone's uniqueness in the classroom. Sounds daunting, I know. It's one of the hardest challenges to teaching digital curriculum — managing people and personalities to encourage creativity and generate results in the form of projects.

Controlling Unfavorable Situations

You must control the situation, but never become confrontational, regardless of the student's tone . Always be serious, but never angry. Listen first to understand, then explain clearly to be understood. If you feel that you are out of control, take a class break and calm down. Then discuss the incident with the person after class so that other students are not involved. This helps avoid feelings of embarrassment for you and for the student.

Your goal is to make all parties involved happy. Convey the fact that you always want a win-win situation and the student to be ultimately happy and satisfied. Show the student that you are there to help, not hinder. Let the student know that you are a resource for them to utilize. This type of giving approach will help generate trust, admiration, and connection between you and your students. Above all, be empathetic to the student's problems and concerns.

Make Proper Ergonomics a Priority for You and Your Students

Everyone will be happier and healthier when they sit properly. Ask students to sit, put their feet flat and have both hands ready to use the computer. Institute a "two hands at all time rule" because it will keep students alert and working properly. You cannot slouch at a computer and use two hands. It is impossible. Should you request that students use two hands on a computer? I explain to students that in the "real world", (I refer to the "real world" often), creatives are paid by the time they spend on projects. All programs have shortcut keys (such as "apple + z" or "control + z" to undo) and all graphics and layout programs have multi-key combinations that are needed for performing certain functions (for example, to scale an object and keep it's aspect ratio, you must hold shift in most programs). Therefore, using two hands becomes the professional approach that everyone should emulate.

Ergonomics is the study of the human body at work. As a science, it has roots in the industrial revolution. Initially, time and motion studies were used to improve workers' performance. Today, computing and medical societies realize how important it is to health.

Besides efficiency, maintaining sound ergonomics helps to eliminate physical stresses that working on computers can foster. Pain in the wrist, forearm, back, neck, and legs can be lessened or eliminated by employing sound ergonomic components including a drawing tablet, a good chair, proper posture, adequate lighting, and an appropriately-sized workspace. These assets may not be present in your teaching environment. You should try to obtain as many as possible because they make a difference in the quality of work and student success.

TEACHING STRATEGIES FOR BUILDING SUCCESS

Understanding Your Objectives

The first question that must be clarified before you start to teach is, "What are my objectives?" What do I want to accomplish? What goals are to be met? There are certain state standards that must be reached when teaching in a public school setting. In college there are certain standards for each department and there are certain requirements that must be enforced for institutional accreditation. With all of those standards and objectives, why do we need anymore? The objectives discussed here are important to the success of a teacher of computer graphics and multimedia in any discipline. I stress the word success. In my opinion, this list has no particular order.

- *Objective:* Introduce new techniques and technologies to the student.
- *Objective:* Develop style by discussing historical and professional references.
- *Objective:* Adhere to your prescribed "state standards" if they dictate curriculum.
- *Objective:* Teach the student new vocabulary related to the technology and design process.
- *Objective:* Develop student understanding of the design process and its relationship to solving problems and completing projects in their discipline.
- *Objective:* Develop "computer confidence" in the student.
- *Objective:* Motivate the student to cultivate new creative concepts, approaches, and content into their work.
- *Objective:* Transfer practical skills and pass on real world experiences to students.
- *Objective:* Direct the student towards completion of a tangible project that is portfolio-ready.
- *Objective:* Critique student work and offer critical feedback and guidance on design, usability, visual, presentation, and commercial strength.
- *Objective:* Present student work to a broad audience (web portfolios).

Focusing on these objectives will help you and your students succeed. Remember: begin with the end in sight. You want your students to finish the course with a new interest in the subject, exposure to jargon and vocabulary words, confidence that they can use computers effectively, and an understanding of the design process within their discipline. You also want the student to develop a new skill set, portfolio- ready projects, and an understanding of how feedback can improve project strength.

Teach in Outlines

Teaching in outlines presents information in a hierarchical structure. Structure allows students to grasp the information in steps. Each step is a building block to the next step. Without the

hierarchical structure, there is confusion on appropriate direction and process.

For example, students in a digital imaging class are using Adobe PhotoShop. What tools or techniques are taught first? What project will be issued to reinforce the use of those tools and techniques? Should digital painting techniques or image manipulation be taught first? What about production using layers and paths? What do we lecture about on the first day? Development of a hierarchical structure is vital to teaching computers, graphic design, and multimedia.

Here's how to teach in outlines. First, perform research. Acquire books, articles, and web content on the technology and curriculum samples or cases. Go to publishers' and booksellers' websites to get abstracts and table of content samples. Read them to discover and learn about the things that are unfamiliar to you. Create a simple list of five major areas that seem important to the technology. Create an outline of these five topics. Write down important information regarding the technology and the applications. Specifically, understand what tools and applications are used to execute projects to completion. Remember to look for hierarchical structure. See how the various books and articles describe use of the technology. Take note of chapters and content. Does the book seem to move from beginner techniques to advanced? Examine other digital curriculums related to your discipline to expand your thoughts on subject hierarchy. Once you feel comfortable understanding the flow of information and the design process needed to complete a project, document it in a lesson plan. Then follow the steps in the plan to completing the process and complete the project. Alternatively, jump around through the table of contents of books to scrutinize the proper hierarchy to fit your lesson plans. Keep it simple. Don't overload your students or yourself with too many concepts too fast. Stick with the hierarchy and the outline. Your major topic outline will help you to figure out what to teach without overwhelming you with too much information. This is crucial to learning in small steps. Small steps in learning will ultimately develop a complete understanding of the subject.

Use a Topic Outline

The topic outline should include this information:

1. *Provide an overview of the technology to the class.* Explain what medium the technology is used for (TV, computer kiosk, video, gaming, print, etc.). Provide the names of the companies who make the applications. Give an overview of the class projects that will be created using these tools and technologies.
2. *Present some new, vital vocabulary words.* These will come up so you need to clarify them early. Explain resolution to a digital imaging class or vector graphics to a digital illustration class on the first day.
3. *Describe the tools, palettes, and menus in overview form.* Use metaphors to relate the fine art world with the digital art world. For example, talk about Adobe PhotoShop having a canvas, a palette, and brushes all for painting — digital, of course.
4. *Describe the creative design process* that the class will go through to develop concepts, source materials, and content for the projects. Plant seeds in students' minds so that they will have creative control and consistently generate new approaches to their art, design, programming, multimedia, and communication pieces.

Talk About it First to Get Feedback and Levels of Experience

Always discuss the subject before everyone jumps to use the computers. Make your discussion interactive. Don't just lecture — question. Make a strong appeal to have the entire class

give answers. What are you asking? Questions that you have devised from your outline. These questions will help you gain an understanding of the experience levels of your students. It will also help generate some background information on the students that may come in helpful later. Shy students, talkative ones, highly experienced, inexperienced, and exceptional students will all coexist within your learning environment.

Have a general discussion that involves the class. Begin with a question directly related to the name of the course. WHAT IS DIGITAL VIDEO? What does digital mean? Does our VCR play Digital Video? These are the questions I ask eager students. Who has heard of Adobe Premiere or Apple Final Cut Pro? What do they do? Who in the class has used them?

When you ask with enthusiasm and you demand involvement, students respond. You will notice that everyone is thinking. There is no better gratification for a student in class then presenting the right answer in a class discussion. Students strive for it. They may give all the wrong answers, but that's fine at this point. The chance to give the right one is worth it. The main thing is that we have succeeded in making them think about the processes, technologies, and applications they will use shortly.

Factor in Practice Time at the Start

Good design work takes a good amount of time. Conceptualization is crucial and changes are constantly upgrading the design. Thus, it is necessary to increase our time for the project. At some point, there is a deadline. Let students know immediately that they should expect to spend time outside of class to work on projects. If the context of the class is not a serious commercial-level audience, make sure practice time is factored into class time. Students learn computer graphics and multimedia in steps. Each step leads to the completion of a technique. The techniques help build the project to completion. The techniques require practice for the ability to execute and also to remember after the class is over. Maybe the person has to go back to work on Monday and use the new skills immediately. Practice must be factored in! If students can't make a commitment to practice they will never learn to complete projects and reach class goals.

Talk About It, Show It, Do It, and Do It Again: Answer Questions and Do It One More Time

This is a process that I use constantly to achieve retention. Retention is the key to student development. If students can't remember the technique, how can they implement it? If you look at students and they give the impression that you are going too slowly, you've hit the mark: retention. There is no such thing as over-teaching a topic. Be sure everyone understands before you move on to the next topic.

Review should be part of everyday lectures. Techniques lead into other techniques. Therefore you can always lead into a discussion on a new topic by reviewing the last topic and it's relationship to the next one (remember the hierarchy of information).

Don't Overload Students with Useless Information

We should not be teaching every single palette, menu, and piece of a software package or technology. Why? Information overload and time. The student needs to learn the material following the hierarchical structure that produces project results. There are things that will be left out simply because they do not rate high in the hierarchy. The information has less value. Therefore, it does not need to be covered formally. Books and student discovery can help teach the less important features and save brain space for the most topical information and techniques.

Projects are Mandatory and Needed — Assign Them, Critique Them, and Improve Them

The most important indication that learning and growth have occurred in art, design, film, video, computer art, graphic design, multimedia, web design, illustration, motion graphics, 2d design, programming, and 3d design are the projects. Practice should come in the form of project work.

Student projects should be evaluated on an ongoing basis. The critique of the student work should provide a forum for comments that provide constructive criticism. The goal is to get comments, not just compliments. The student must also realize that what is said is opinion only and can be discounted as easily as it can be used for improvement in the art-making process. However, the design process has specifications that need to be followed to complete a project accurately. The designer cannot alter these "specs". Elements such as page size, color usage, typography treatments, media, and message are all dictated in the design process and instructions must be followed. After critique, adequate time should be given for students to refine their work and then submit it for a grade.

Critique for design projects in any discipline may include criticism on:

- *Concept:* original idea that facilitates and supports a design solution
- *Development:* research and design aimed at defining project goals and strategies
- *Technique:* skills and processes used to execute design production
- *Style:* specific approach to creating unique identity and definitive cohesion within the project design
- *Usability:* functionality and effectiveness within the media which is related to stated goals or specs
- *Output:* adoption into final deliverable (print, web, CD-ROM, Digital Video, DVD, executable application)
- *Presentation:* visual and verbal summary of the value and success of the project

Stifle Disruptive Students Early

Teaching is difficult enough without having a disruptive student. Usually disruptive students come in pairs of two. The word RUDE is nonexistent in their vocabularies. However, you must be polite and provide verbal and nonverbal signals that you want quiet when speaking and during in class work periods.

Typically, talking between two students is common. Simply and politely, ask everyone to listen to you now. That will stop talking sometimes. If it is persistent, stand near the talkers and ask them directly to wait until break to talk. Explain to them that the class is going to start and that everyone needs to work in a quiet environment. If it gets bad, speak to the student after class and explain that there are others who cannot learn with the constant disruptions. Explain that everyone is paying for this class and that talking is slowing the pace and the success of the class. This should help curb or solve the problem. The last resort: speak to your supervisor about possible solutions.

Always remember to require headphones for students working on multimedia projects containing audio.

Don't Do the Work for the Student

You have heard the proverb many times. Give a man a fish and feed him today. Teach him how to fish and feed him forever. It's the same with teaching digital coursework. The student must perform the techniques over and over again to learn. If we try to help students by sitting at their computers and doing the work, we are actually hurting them . Students will expect the teacher to fix problems by clicking a few buttons. That's not the case. The teacher should rarely touch students' computers. The exception is in extreme situations or when students have gone way beyond

where they should be and now need to have their screens reset.

I tell students that it's easier for me to fix a problem than for them try to figure out the solution based on what they know. Sometimes, I encourage students to think about what the problem is and try to find a solution on their own — then we will discuss how the outcome was derived. Thinking through a problem is part of the learning process and design process. It is also important to help students become problem solvers.

Save Early, Save Often

Institute a blatant policy on saving. Too many times I have heard horror stories and consoled distraught students after they have had digital tragedies. I've seen it all. Zip disks going into CLICK DEATH, where the Zip drive is clicking your disk and corrupting your data (Iomega was sued for this), a meltdown of media due to being left on the car seat in hot sunlight, lost files and disks, and crashed hard drives. It happens. We should be prepared with backups. The student should be saving constantly. Computers crash frequently, regardless of platform, brand, or operating system. If we have created something that is important, we should be saving it in two places. By the second or third class meeting, you should have a formal lesson on saving. You want students to understand how to save, why it is so important, and where it is done.

All students should have external storage media with them by the second class. A zip or writable CD-ROM if applicable to your workstations. Also, students can use plug-and-play Firewire hard drives that provide hundreds of gigabytes of storage space. Show the student how to access external media. Teach them how to move and delete files. Show them where they can save on the local hard drive or server if available. Make saving a priority. There is nothing worse than working on something for hours and then losing all the work because you forgot to save. As teachers, we don't want our students to experience that dilemma. It is our job to remind them frequently and to train them to save early and often.

Utilize Real World Examples

Every time I explain a topic, an example from the real world is shown. Many times it's work that I had a role in, many times it isn't. By using real world examples we justify the techniques and approaches being taught. We show students that this is something they may be doing in their careers. We also alert them to the fact that the skills and techniques they are learning are important to their technical and professional development. For example, I'll show a magazine spread and explain text wrap, alignment, typography, and design. Then I'll mention that those design skills and techniques are very important if you want to work in publishing production and design. Sometimes that will make people sit up in their chairs and listen a bit more seriously.

Provide Early Timelines for Exams and Projects

Timelines are crucial to project management. Providing a timeline to your students before the course begins is essential to getting projects and assignments completed on time. The timeline also provides a visual workload for students to factor into their schedules and lives. On the timeline, list the dates projects are due, when exams will be given, and tentatively when topics will be covered. This timeline should be part of the syllabus. The timeline will also help you teach topics efficiently and help you to not forget topics.

Always Use the Correct Vocabulary

I hate when computer teachers confuse memory (ram) with disk space. Someone says, "My zip is full, I'm out of memory." That person is not out of memory; they are lacking disk space on their

storage media. We must use the correct vocabulary. The jargon that exists in computer graphics, multimedia, the Internet, and within the world of computers is endless. We can't know it all, but we as teachers should know our discipline's variety. Understanding jargon is crucial to participating in everyday operations. If you forget the difference between Fahrenheit and Celsius and you are a meteorologist, you are in trouble. The same holds true if you are a digital production artist and you forget the difference between an .EPS file and a JPEG file. Use the correct vocabulary in lectures, notes, projects, and in answering questions. It will also raise your level of credibility as the instructor and perceived expert.

Administer Vocabulary Exams

Students need a strong digital vocabulary to interact professionally with colleagues, vendors, potential employers, clients, and industry. Understanding vocabulary allows the student to read and understand books and articles on the subject more fully. In addition, this jargon is found in the project process. Using vocabulary correctly and giving vocabulary exams are the most successful methods for grasping vocabulary.

Involve Everyone During Questions and Feedback

You are a resource for the student. Provide feedback and direction, but don't do the work for the students. Whether it is creative conceptualizing or digital production, students must explore the process. Answer questions with questions. Make certain that students understand the question and have genuinely not found the answer. Many times students will take a passive approach and ask a simple question that they should know or will ask simply to get the instructor's attention. Try to encourage learning during questions. Get the group involved in questions. Have classmates help out during question and answers sessions. It helps sharpen vocabulary words and concepts for students. When feedback is being given during critiques, be sure everyone is involved and giving their constructive comments. This process helps evoke a synergistic team approach to analyzing projects.

Build Confidence from Start to Finish

Lack of confidence is a terrible state of mind that occupies many students. Typically, older and returning students show it the most. As teachers, it's our job to instill confidence in students. How we do it requires some extra effort on our parts. Here are some things to remember when you want to build confidence:

- Don't patronize students. Never talk down to them.
- Listen first and explain second. Understand students, then teach them.
- Never allow negative talk to consume the student. Regardless of the situation, let the student know that if they put the effort in, rewards will follow.
- Be a coach, project manager, mentor, and motivator.
- Let students know that you are there to help them succeed.

Act as an Invisible Project Manager

The project manager is the person who makes sure that the project is done on time and correctly. We must act as project managers when teaching computer graphics and multimedia classes. The students we teach are going to be working on projects. There will be obstacles that hurt the project process. As teachers, we must help the student remove the obstacles that hinder project completion. Ask students what is happening with their projects. What stage are they at? What is left to do so that projects can be completed? Ask what

problems are being encountered that are stopping the progress of the project. Offer solutions and provide updates on when projects are due and how much time is left for completion.

SETTING UP YOUR LABORATORY AND CLASSROOM ENVIRONMENT

Take an Active Role in the Development, Maintenance, or Upgrade of your Lab

The way to learn about technology purchasing is to get your hands dirty in it. Dig in to catalogs and websites. Find out the names of manufacturers, vendors, and get a sense of what prices exist (the catalogs will tell you that). Developing a lab requires you to take the time to learn about the environment. Lab maintenance is a good way to keep the lab running well. You should acquaint yourself with standard maintenance procedures for each platform (especially the one you use). They can be found in your systems owner's manual. You can also use software tools such as Norton Utilities to help you maintain and repair your workstations. Learn about future upgrade items by researching. Find out early when there are new versions and tools that are important to progress. Understand the technologies early and then, when they are instituted, you will be a step ahead.

Determine Your Needs on Paper First, then Write the Purchase Order

Setting up a computer lab requires financial, organizational, technological, and logistical aptitudes. Also, it demands some insight regarding the politics and red tape present in your organization.

The best way to organize any project is to write it out. Get down to the practical aspects and develop an outline for the new or upgraded lab. Address these areas in your brainstorming session:

- What is your anticipated budget? Sometimes this number changes, so prioritize.
- What is the student maximum per course? How many courses per day?
- Which courses will be taught in the lab? Information Technology, Computer Science, Multimedia, Graphic Design, Video, or perhaps all of them?
- Will the lab need internet access? It most definitely does, regardless of the class.

Nevertheless, remember your priorities. The Internet is a necessity in some courses. Other courses may not need internet capabilities. However, all classes can benefit from using the internet for research, exhibition, or communication.

- Will the lab have to accommodate students with disabilities or special needs? This is a critical concern in some institutions. Typically equipment and furniture considerations differ in this situation.
- What are the electrical and lighting situations in the room? Will outlets or conduits have to be installed? Will lights have to be installed to improve the functionality of the space?
- Based on the courses taught in the classroom, what programs need to be purchased?
- What platform (Macintosh or Windows) does the staff prefer? What platform is dominant in the industry? What platform currently exists (if any)?

A clear view of priorities will emerge after answering the above questions. Start to prioritize the truly important items. Add the luxury items to a wish list and hope for future budget money. An example of priority items include: CD ROM burners, color laser printers, digital cameras, constantly updated versions of software, presentation panels, and internet access. Without these items, you cannot run a lab and teach an entire program.

What to Use for Graphics and Multimedia? The Age-Old Question: Must We Use Macintosh or Can We Use Windows?

I am asked this question at least 100 times per year. My answer stays the same throughout OS changes, new versions, and bad and good news. The answer is that it is up to the staff. Whatever the staff is most comfortable with is best to have. Macintosh is widely used throughout advertising, digital production, and new media. Windows 98/2000/XP is dominant in business applications, information sciences, and computer science. Running graphical software and producing multimedia on the Windows platform is now as seamless as on the Macintosh. The real question is, again, what does the staff feel most comfortable with? Moreover, what is the industry standard? There are some distinctions that bring the old folklore that Mac and Windows PC's were mainstream competitors and they did not work well together exchanging files. That has changed dramatically since about Mac OS 6 (1993). That's when Apple bundled the application PC exchange with the OS. The extension allows Windows media to be read on Macintosh systems — right out of the box. Windows does not have that ability yet. Therefore, Macintosh has been touted as the friendlier platform in some circles. Throughout the publishing industry, Macintosh has been a standard platform since the inception of desktop systems.

Three-dimensional modeling, motion graphics, and multimedia applications gave way to the need for workstations that employed multiple processors and huge storage drives. Workstations are used in television production, film effects, video, DVD and CDR authoring. The workstation allows a massive amount of processing power to output gigantic files. Macintosh systems cannot provide the muscle that some workstations can. However, Macintosh is competing in the desktop arena by providing innovative hardware and software solutions for DV and DVD production. Apple computers allow users to capture, develop, and edit full-length digital video using a Digital Video camera. The digitized video can then be output to multiple media including web, broadcast, video, CD-ROM, and DVD.

Here are the main differences between Mac and Windows from a user's point of view:

- Windows systems on a base price level can be purchased at a lower cost than Macintosh. The reason is that there are so many manufacturers of windows-based computers in the United States that prices fluctuate and there are constant price wars in the PC market. Macintosh is a brand that owns its platform. No other company manufactures products running the MAC OS. Apple products are sold at a fair market price and are very competitive with comparably matched Windows Systems. However, a few operational differences make Macintosh more desirable for the print, multimedia, and content creation arenas.
- Macintosh accepts and reads files on the Mac platform and will open Windows files created with the same application. Windows will do the same, but will only read Windows media.
- Macintosh allows digital video input and output right out of the box. Previously, many Windows computers could not say that. If you want Firewire (ieee1394 or Ilink) technology for digital video use on the Windows platform, you must buy an aftermarket video board. You must install it and hope it is compatible with your computer and digital video editing software. Most PC manufacturers are adding Firewire cards bundled with their systems to avoid incompatibility issues. Macs also typically come with digital video editing software when purchased. It's not the high desktop applications we use in the professional industry, but is enough to create, edit, and output digital video — right

out of the box. It's great for educational settings where content and basic knowledge are more important than teaching high-end applications.

- Macintosh computers have network capability directly out of the box. All that is needed is an Ethernet hub and Cat 5 cables and the AppleTalk takes care of the rest. For Windows machines, an Ethernet card would have to be purchased for each computer on the network as well as a hub. The Macs come with Ethernet built right in.

Bottom line, it does not really matter. Windows computers may lack some simple features that we have come to adore on Macintosh, but when it comes to sheer horsepower, Windows XP multiprocessor workstations are the choice for the professional film and TV editing, three- and four- dimensional modeling, and animation developers. The price factor makes Windows a bit more desirable, but Macs give added features out of the box that provide networking and multimedia capabilities to students. In a digital design lab environment, Macintosh may provide some functional advantages. In a computer science environment, Windows machines are typically more desirable. Ask your colleagues and staff what they prefer. Then ask them why. Collect the information and make a majority decision based on budget and priority.

Prioritize Your Purchase Regardless of the Platform and Put First Things First!

You must have your priorities in order when you are developing a computer lab. The decisions you make when the lab is delivered are the same decisions that come back to haunt you when you need more resources or things do not meet expectations.

- *First priority:* Make sure that you have enough computers for every student. If the class size exceeds the number of computers due to enrollment, cut class size. If class size is too large, you will need to make shifts of student to work on stations. Your teaching load will double per class because you will be shuffling around students to get everyone working on something. Inevitably, student work will suffer. There is a better way. Demand there are enough computers for each student.
- *Second priority:* Get as much ram as you can afford. Load up. You'll be happy when software versions change and your hardware budget is on hold until further notice.
- *Third priority:* Removable storage drives such as Iomega ZIP drives. Students need to back-up and transport their work. These drives allow them to do that. Having one drive becomes chaos. Saving and archiving become afterthoughts and hassles to the students. Also a good choice, but a bit more expensive for the student compared to a ZIP disk are removable Firewire hard drives. Eliminate the fear of losing files by making student backup an important priority. Also needed are archival media and drives, including CDR and DVD. These drives should not be used for primary, daily storage, but for final project output and archiving.

If You Develop Any Computer Lab Learning Environment, Try to Make the Following Items Part of Your Proposal

These will make teaching much more manageable. I'm sorry if these items are considered luxuries due to budget constraints. However, I cannot stress the importance of these items on what I call "quality of lab teaching life".

- *Hardware security system* including cables and padlocks for systems, monitors, and peripherals to keep the lab safe from theft.
- *Software security system* to lockout vital folders like the System Folder. These are now the duty of the lab manager. The needed functions can be found in the latest network operating systems for each platform.
- *A presentation panel for display on a screen or wall.* Although expensive, these technology learning tools are extremely helpful in the digital (smart) classroom. A decent one will cost you $3,000 to $4,000 dollars. Make sure you consider this item seriously when distributing your budget.
- *Pneumatic adjustable chairs.* This should be nonnegotiable. Bad chairs breed bad work habits. To help ensure an ergonomic lab environment, you should insist on the best chairs you can afford.
- *A file server and an Ethernet network.* This will help you transfer files and applications between stations and will allow maintenance to be easier with all machines connected. You will need this for internet access throughout your lab and to institute a software security system. Add a tape backup to the configuration for complete backup of the server.
- *Removable, rewritable, cross platform storage device* such as a Zip drive. Students need these to backup and transport files.
- *Internet accesses via a high-speed line or backbone,* especially if you are teaching a web centered course. A T1, T3, or cable connection is the minimum.
- *Server space and FTP access for web classes.* You should demand this if you are teaching a web design course.
- *A scanner for image acquisition.* One is the bare minimum you will need. This is a necessity. Without it, content will be virtually nonexistent in digital imaging and layout courses. Also include a digital camera for shooting stills and small video clips and a digital video camera for capturing full-length digital video and audio.
- *Enough computers for all students to have their own workstations during class time.* Without this, you are really challenged. It is not an impossible situation, but it requires some compromise to your teaching schedule. Inevitably, students will suffer. You can't watch and learn computer graphics and multimedia. You have to be hands in and knee deep, practicing constantly.
- *Lab hours outside of class.* This will allow students to practice and work on projects outside class time. Even if they are limited to small increments, lab hours are necessary for student abilities and confidence to grow. There has to be someone in charge during lab hours, so think about work-study students or graduate assistants to help with lab management.

CONCLUSION

Building student confidence, developing project- based skills, presenting vocabulary, and working towards project -based goals are crucial components in helping students succeed in digital coursework. But before you can do it, you must become comfortable with not knowing everything and understanding that you will be growing perpetually. Becoming an expert at teaching digital subjects presents very demanding challenges. Understanding, adapting to, and conquering those challenges will be realized through perpetual research and raw experience.

The future will undoubtedly present more and more interdisciplinary scenarios for programmers, designers, artists, production professional, writers, and musicians. This surge towards collaboration will be reflected in digital education. In the past decade, multitudes of schools have instituted new programs in multimedia, interactive multimedia, new media, educational technology, informa-

tion technology, instructional technology, and many more multi-discipline disciplines. The convergence of media, process, skills, and deliverables makes teaching computer graphics and multimedia an extremely challenging, dynamic responsibility that requires artists to learn more programming and programmers to learn more about visual communication.

Chapter 1.7
Evaluating Learning Management Systems:
Leveraging Learned Experiences from Interactive Multimedia

Katia Passerini
New Jersey Institute of Technology, USA

ABSTRACT

This paper maintains that the use of multimedia content in Web-based instruction — facilitated by the proliferation and standardization of learning management systems (LMS) — calls for the extension of traditional multimedia design and evaluation guidelines to the Web. The compliance with these guidelines needs to be thoroughly evaluated by any institution using (or planning to use) Web-based learning management systems. In addition to providing criteria and examples for the evaluation of these systems, the paper includes a survey instrument that can be used for university-wide assessments of the design effectiveness of technologies that support learning. As an example, the proposed evaluation instrument is applied to a learning management system developed at a large university in the United States. While the assessment refers to one system, the model, the instructional and design evaluation criteria, and the questionnaire are built for use in any organization conducting a formative and summative evaluation or a selection of learning technologies.

INTRODUCTION: LEARNING MANAGEMENT SYSTEMS

Learning Management Systems (LMS) are Web-based applications that support online teaching or supplement face-to-face instruction. Typical functionalities of LMS include Web course design, Web course collaboration tools, and Web course management (Hall & Hall, 2004; Hills, 2003c).

The **course design** features provide templates for course organization. Instructors control the content and have some impact on the screen layout (changing features such as color and screen placement). Students can post information on personal Web pages or can create areas to post

assignments and discussion topics. Search tools are available for quick access to materials.

The **collaboration tools** include synchronous (chat) and asynchronous components (discussions areas similar to listservs). Faculty can use bulletin boards to post course-related announcements. Electronic messaging within the LMS provides a repository for course-related messages. Whiteboards are used especially with mathematical and visual information. File sharing and workgroups are particularly useful for team-based activities enabling simultaneous file editing by several users.

The **course management** features enable student grading, performance tracking throughout the course, and the calculation of time spent using the software applications. They also enable instructors to design online quizzes, randomize questions from a database, and assess response time.

In addition to the above, a number of administrative features provide security and technical support for faculty and students. Table 1 lists typical LMS areas contained in many commercial and open-source applications such as WebCT, Blackboard, and Lotus LMS.

EVALUATING LEARNING MANAGEMENT SYSTEMS

Stoner (1996) defines a learning technology as any application of technology for the enhancement of teaching, learning and assessment. This definition includes the use of network communication systems and embraces a large number of multimedia and Web applications. Learning management systems that enable classroom instruction on the Web and/or support face-to-face instruction with access to online learning repositories of course materials fall within this definition of "learning technology." When integrating a learning technology into a traditional curriculum, a thorough evaluation of its key design and instructional characteristics is a critical element and a pre-requisite for its successful implementation (Bersin, 2005; Hills, 2003b).

Stoner proposes a system design approach to the integration of learning technologies into traditional courses (or sections thereof). This approach draws on methodologies widely used in the design and implementation of computerized-information systems (Lucas, 1994; O'Brien, 2005) and in systems approaches to instructional design (Gagné, Briggs, & Wagner, 1988). Stoner's model suggests a careful data collection on course type, students, and resources available. He encourages

Table 1. LMS Features

Course Design Features	**Collaboration Tools**
Instructor-centered sample course	Discussion options

the research of alternative solutions: "These will need to be formulated in some detail, identifying the learning technology [courseware] to be used and how it might be used and integrated within the course(s) being considered."

This paper presents a framework for the assessment of LMS leveraging the system design approach suggested by Stoner. Particularly, it relies on lessons learned in the design of interactive multimedia. It applies the design evaluation criteria on a specific LMS developed at the George Washington University, the Prometheus system, to introduce a specific example of the evaluation protocol here presented.

Types of Evaluations

There are several approaches to conducting evaluations (Johnson & Ruppert, 2002; Hills, 2003b). Ideally, several types of evaluations should be implemented. In reality, financial, temporal, and human resource constraints limit the options (often in favor of "late" summative evaluations). Four main approaches to evaluating learning technologies are seen in Table 2.

Formative Evaluation

Formative evaluation is testing conducted on selected samples of the user population while the product is still being developed (prototypes). Formative evaluation use open-ended methods, survey questionnaires, or confidence logs (users' self-assessment of their knowledge). The key constraint of this method of evaluation is its timing. Authors describing the planning efforts of formative evaluations note that it is difficult to plan and implement testing early enough so that changes can be made (Alessi & Trollip, 1991). Often, resource constraints do not enable the administration of formative evaluations.

Summative Evaluation

Summative evaluation is a process that concerns the final evaluation. This evaluation usually focuses on the user (rather than the application) because it is conducted after the product release. It is used to inform decision on future developments, as a product review, and as a user-satisfaction data collection instrument. Traditional surveys or assessment tests can be used, as well as observations, interviews, and other qualitative and quantitative data.

Illuminative Evaluation

The aim of illuminative evaluations is to discover what factors and issues are important to the participants in a particular learning situation, which may differ with the developer's judgment. Draper, Henderson, Brown, and McAteer (1996) state that "illuminative evaluation has a systematic focus on discovering the unexpected, using approaches inspired by anthropology rather than psychology," and that these approaches have a significant effect on the users.

Integrative Evaluation

Integrative evaluation is "aimed at improving teaching and learning by better integration of the

Table 2. Types of evaluations

Evaluation Type	Purpose
Formative	To help improve the design (conducted during development)
Summative	To assess the product and its functionality (conducted after release)
Illuminative	To uncover important factors latent in applications
Integrative	To help users extract all the benefits of a learning technology

learning technology into the overall situation. It is not primarily either formative or summative of the software, as what is both measured and modified is most often not the software but surrounding materials and activities. It is not merely reporting on measurements as summative evaluation is, because it typically leads to immediate action in the form of changes" (Draper et al., 1996). For example, if all the students in a classroom complain about the use of the technology for a particular learning outcome, the instructor and the developers need to reevaluate the tool and its current application. "Is the feature able to achieve its intended purpose?" If it is not, the developers should promptly modify the system, based on user feedback.

This paper focuses only on the first two types of evaluation: the formative and summative models. The scope of the discussion is limited to two models in consideration of space limitations and to present examples of LMS evaluation models actually run at a large university. It describes the content and assessment procedures for applying these evaluations to learning management systems. The paper draws from the interactive multimedia literature to identify frameworks and criteria for LMS assessments.

CRITERIA TO EVALUATE LEARNING MANAGEMENT SYSTEMS: BORROWING FROM INTERACTIVE MULTIMEDIA

Interactive multimedia instruction is traditionally grounded in several years of experience with interface design, human-computer interaction and computer-supported mediated learning. In the mid-and late nineties, instructional multimedia was partially replaced by LMS systems (Taylor, 2003). New applications competed in emerging as tools to facilitate transfer of in-class materials to the World Wide Web. Initially, these systems failed to leverage the design lessons from interactive multimedia because of the then clear hiatus between the Web and multimedia systems. Today, pervasive broadband access has brought about the possibility of delivering multimedia content in a Web space with a relatively low bandwidth impact. Finally, several multimedia applications have started to be transferred online (Watson & Hardaker, 2005) through Macromedia Flash and Java programs, lowering the gap between interactive multimedia systems and LMS.

The distinction between interactive multimedia and the Web is becoming "blurry" (Hedberg, Brown, & Arrighi, 1997). If interactive multimedia was perceived to be bound to the shell of a physical container (the cd-rom), today's online delivery capabilities enable hyper-linking and navigation as in a Web-based system. And where interactive multimedia systems are still constrained by the boundaries of a self-contained application, also LMS suffer from the same limits. As in interactive multimedia products, LMS rely on a self-contained (online) shell within which both instructors and students (and only the instructor and registered students) coherently navigate to organize and retrieve documents (within the available templates) (Hall & Hall, 2004). In this context, the areas of coincidence among interactive multimedia design and Web-design guidelines increase. As the coincidence grows, lessons learned and validated interactive multimedia frameworks can be leveraged to evaluate the effectiveness of an LMS (before its curriculum integration) (Coates, James, & Baldwin, 2005).

As discussed next, an examination of multimedia and Web development principles furthers these statements eliciting a close mapping of interactive multimedia design guidelines with Web-based instructional systems design guidelines. It extends multimedia design principles (for example, Reeves, 1993) to LMS models.

Designing multimedia for instruction requires major attention to two main factors: coherence and cognitive load (Yi & Davis 2003). Coherence of screen design is a key element of comprehension

as it facilitates the construction of the mental models for the learner. The higher the coherence, the easier it is for the learner to comprehend.

- **Coherence** needs to be reached at a *small scale,* linking pieces of information together for local coherence, and on a *large scale*, reminding the user about the relationships between the current screen and the learning domain.
- **Cognitive load** is defined as any effort in addition to reading that affects comprehension (i.e. navigation efforts or adjustment to the user interface). The higher the cognitive load the more difficult it is for the learner to comprehend. Strategies for reducing the cognitive load include creating a good balance on "distance", "focus", and "proportion" (Szabo & Kanuka, 1999). For example, key elements on the screen can be placed or given a different layout or shape based on importance. Cognitive load is also reduced by using clear navigational strategies. For example, hyperlinks/buttons need to be user-friendly and easily understandable also by a novice user.

Multimedia applications follow screen design, navigation and interactivity design guidelines that are informed by cognitive load and coherence principles:

- *Ease of use*. The perceived ease/difficulty of user interaction with a multimedia program: the more intuitive the application user interface, the less impact on the user cognitive load.
- *Screen design*. Screen design in multimedia relates to the coordination of text and graphics to present a sequenced content. This content facilitates understanding (Mukherjee & Edmonds, 1993) with each screen providing effective instruction, appropriate navigation tools and pleasing design/visual aesthetics (Milheim & Lavix, 1992). Each screen must display a **navigation toolbox** at the bottom, **title and instruction** areas at the top of the screen, with the **body area** containing media clips in the center (Stemler, 1997).
- *Information presentation*. Visual clues and information on the screen cannot be cluttered: too many representational clues (icons) or too much declarative text in one screen creates confusion and overwhelms the user (Overbaugh, 1994).
- *Level of interactivity.* Interactivity is a key distinctive feature of interactive multimedia and should be provided frequently, at least every three or four screens (Orr, Golas, & Yao, 1994).
- *Navigation*. Navigation should occur through simple interfaces, using facilitating metaphors and familiar concepts (Gurak, 1992). The icons should clearly show whether they are hyperlinks to other screens (by color, form, or mouse-over effects).
- *Quality of media/media integration.* Individual media (text, sound, video, and animation) within a multimedia application need to be synchronized based on content, space, and time of the animation.
- *Mapping.* Thuring et al. (1995) suggest several hyperlinking guidelines. They include the clear identification of hyperlinks, the visualization of the document structure, the inclusion of navigational tools, and so forth.

Web design guidelines are closely related to design principles identified in interactive multimedia. In the following list, design principles identified by Jones, Farquhar, and Surry (1995) are mapped to interactive multimedia guidelines. For example, well-designed **Web-based application systems** need to:

1. **Provide structural clues:** *Coherence in interactive multimedia*. Information needs

to be presented in a consistent manner with clear identification of the structure (Elges, 2003). Strategies include providing overview areas, maps, fixed display formats, and consistent placement of section titles.

2. **Clearly identify selectable areas:** *Navigation in interactive multimedia.*Clarity is accomplished by following standard Web conventions (i.e. underline and blue for active hyperlinks) or using icons that clearly indicate alternate navigation paths. A subprinciple to this guideline is to clearly indicate selections made, so that the users have a contextual understanding on where they have been and their current location.
3. **Indicate progress made:** *Interactivity in interactive multimedia.*This is an option particularly important when users are navigating through instructional material or taking an online assessment. Feedback on the status of the lecture or progression on the quiz eases navigation and favors cognition.
4. **Provide multiple versions of instructional material:** *Information Presentation*. This includes offering a text-only option, a text and graphics option, an audio narrated presentation, a video, or a variety of media accessible through high speed networks (Fleming, 1997). This is particularly important in order to guarantee broader accessibility (Johnson & Ruppert, 2002).
5. **Offer contextual help:** *Ease of use*.Contextual help facilitates navigation and ease of use (Tarafdar & Zhang, 2005). For example, if users experience difficulties in retrieving materials, specific browser options and configuration eases progress.
6. **Keep pages short:** *Screen design*.Scrolling may not be enjoyed by users (del Galdo & Nielsen, 1996). Information should be presented on sequential pages, providing the option to print the complete document through a single packaged file, conveniently placed in the first instructional screen.
7. **Link to other pages, not to other points in the same page:** *Mapping.*Long documents and text should be broken down in sequential pages. The users will have the ability to "jump" to other sessions or go back to the same paragraph by simply using back buttons and "breadcrumbs."
8. **Select links carefully:** *Cognitive load.*Too many links in the same page may overwhelm the student and disorient (del Galdo & Nielsen, 1996). Links should be placed only at the bottom of the page or at the end of the text that they refer to. Links conveniently placed within the paragraphs offer contextual information and clarification for the learners.
9. **Label links appropriately:** *Navigation*. Some textual links or icons may not clearly indicate the destination area. Particular attention needs to be paid to content synchronization.
10. **Keep important information at the top of the page:** *Screen Design.*As dynamic text, such as "flying" or moving effects, lower attention and focus (Yi & Davis, 2003), and are not supportive of learning, important information should be static and placed at the top of the page.
11. **Links and information must be kept updated:** *Information Presentation & Mapping.* Both content and links to other material need to be tested on a periodical basis to check the availability of the link ("active" links).
12. **Limit overly long download times:** *Interactivity.* As "traditional human factor guidelines indicate 10 seconds as the maximum response time before users lose interest" care should be used to decrease file size and download times (del Galdo & Nielsen, 1996; Tarafdar & Zhang, 2005).

In summary, the principles above map and extend guidelines applicable to interactive multimedia. These principles can provide guidance on how LMS supports learning by decreasing the cognitive load and increasing coherence. The next section presents an example on how these guidelines can be applied to uncover limitations with existing systems and systems under-development.

EXAMPLES OF EVALUATION: PROMETHEUS FORMATIVE EVALUATION

Having reviewed design principles and instructional objectives set forth in the literature, this section of the paper applies these principles to the evaluation of an online courseware application, Prometheus (Johnson & Ruppert, 2002). Prometheus was developed at the George Washington University starting in 1997. The Prometheus LMS evolved during its development through a series of formative evaluations (similar to the model presented in this section) and summative evaluations (described in the next section). The assessment process benefited the design of the system. It was conducted by a team of instructional designers at the Center for Instructional Design and Development of the university, including the author. The formative evaluations informed the development team of improvement needs. An example of the design guidelines is discussed below. The evaluation is conducted on a 5-point level (using Harvey balls to represent Very Low to Very High levels) and is summarized in Table 3.

Prometheus' main menu (navigation toolbox) identifies the structure of the course and the key course content. The main menu display is fixed, and coherently placed on each screen (see Figure 1).

Hyperlinks within pages are labeled with text descriptions and standard colors for visited/unvisited links are used. Additional hyperlinks that enable editing and interactivity are clearly identified by consistent yellow boxes placed at the top of each frame (see Figure 1).

Prometheus does not provide feedback on the progress made in the completion of the coursework. In the communication section of Prometheus, the discussion area, the provision of feedback on the navigation of the threaded/unthreaded messages is lacking. The user does not know how many messages are left to read when navigating sequentially through each discussion response. Figure 2 shows the navigation screen in the discussion area. Help on the contextual position of the user is missing (How many messages have been read? How many yet to read?).

Prometheus enables the integration of video and audio to any type of text and/or PowerPoint presentation. Faculty can deliver their lectures using a variety of media. A re-sizeable pop-up window with a multimedia presentation is available to students (see Figure 3). This window enables learner control (play, pause, and stop buttons) and self-paced learning.

Although Prometheus is a particularly user friendly interface, for example, no formal directions and Frequently Asked Questions (FAQ) responses to configure users' browsers are available. Contextual support with instructions on download could be easily integrated into Prometheus, rather than being handled individually and redundantly by each instructor.

The length of the pages in Prometheus vary depending on the amount of information each instructor uploads into the system. Prometheus pages may remain short, become very lengthy, depending on the instructor's preference for typing a lecture in Prometheus or simply uploading a document file that the students can download.

Prometheus does not enable hyperlinking within the same page (thus burdening the cognitive load). A new window will open if a file is being downloaded or a hyperlink has been selected.

Prometheus enables hyperlinking in specific and coherent areas. Although users can always

Figure 1. Navigation and information presentation areas

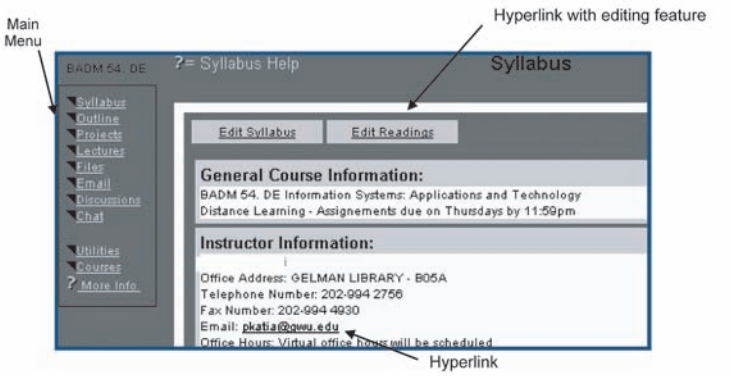

Figure 2. Feedback on navigation

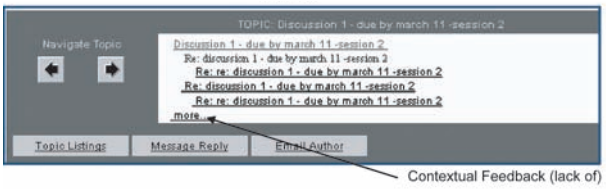

Figure 3. Multiple formats integration

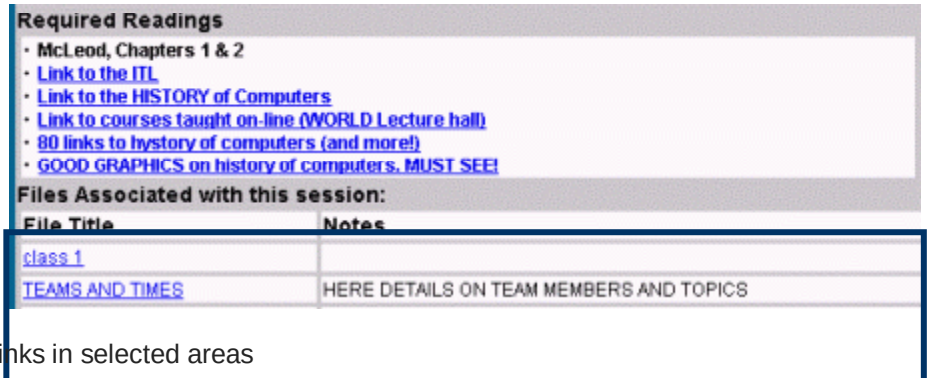
Figure 4. Hyperlinks in selected areas



create links in any area by using HTML commands, Prometheus fill-in forms enable posting of URLs and other class materials only in selected areas (see "required reading for session x" or "files associated with session x" in Figure 4).

Links in Prometheus use text that is explanatory of the function that the selected area will accomplish. Contextual help that provides an overview of features is also available on selected screens. Labels are accurate.

Faculty has little control of the placement of information in Prometheus. Most of the placement in the interactive areas (files, projects, and discussion) is based on time of the posting and cannot be rearranged in different order. The forms in Prometheus can be used or left blank. If they are left blank, they do not appear on the screen. If filled, the order cannot be rearranged by the instructor by level of importance for the specific subject matter.

This criterion applies only to the information that is pertinent to the functioning of the system (and not the material posted by the instructor). A control mechanism to verify the "active" links and

restores back-up files is a needed improvement.

Although downloading time will vary depending on type of connection, modem speed and location (U.S. or abroad), the communication areas of Prometheus (i.e., discussion) suffer from long wait times to navigate through messages. Improvements in iterative releases of the software have decreased this problem, although it still remains substantial for users outside the campus.

Areas for improvement: the evaluation shows that Prometheus could be improved in:

- **Interactivity features:** Re-designing the discussion areas to provide contextual feedback and better navigation.
- **Technical support:** Offering users printable manuals and additional help on how to address the technical problems associated with browser configurations.
- **Screen customization (alias "spatial" and "temporal" synchronization):** Allow faculty and content developers to manipulate the layout and place the information that they consider most relevant in the top portions of the screen. A layout that constructs hierarchies of information based on the time of the posting is cumbersome. Allowing users to manipulate placement and order of uploaded information helps in the accomplishment of the learning objectives and guarantees that important information is not overlooked.

The implementation of the above recommendations, and iterative designs conducted from 1997 to 2003, enabled Prometheus to compete with commercial courseware applications and expanded its reach beyond the George Washington University community, for which it was originally intended. In 2003, Blackboard purchased the Prometheus system to integrate some of its developed features in their product offerings. A key factor in the decision to purchase the product was its high response to the needs of the teaching and learning community. This community was better served by using the results of the formative and summative evaluations described here. An evaluation guide for the assessment of LMS systems and their integration within a curriculum is included in the remainder of this paper to encourage an informed review of commercial applications. Suggestions for criteria and survey administration options are also included.

SUMMATIVE EVALUATION: ADMINISTRATION AND CRITERIA

While the formative evaluation was used as part of a process to improve the software during the development, it represented only a selected group of power users. Broader summative evaluations of the user population (faculty and students) enable corrective and developmental maintenance to comply with user expectations.

The evaluation instrument presented is developed on the basis of the interactive multimedia design principles earlier described. Each question in the scale (item development) is based on a set of related criteria for the evaluation of interactive multimedia products (Reeves, 1993). All the items in the scale are related to specific related domains. The survey measures attitudes and opinions on a self-reported 5-point Likert scale. Criteria for evaluation are based on the perception of interface design and the perception of usefulness of the application by users (students and faculty).

Administration

The survey questions (see Appendix 1) should be administered to two groups of users (faculty and students). Timing of the survey administration is an important factor — it should take place preferably at the end of an academic semester. In order to enable the evaluation of features that were used in the classroom, respondents should be enabled to access only questions relative to the features they used.

Participation in the survey questionnaire may vary. Different strategies could be used to encourage all system users to complete the online survey. For example, incentives could be offered, such as a drawing of free computer software could be conducted for all student respondents. Similarly, faculty participation could be encouraged. Alternatively, participation in the survey could be required of all users (as long as anonymity is guaranteed). For example, users may not be able to access any of the features before they complete the online questionnaire. To avoid user frustration or disruption of user's work schedule, users could be warned that they will be able to access only 10 additional working sessions, before the system will prompt them to complete the survey in order to be able to proceed. They may choose to take the survey earlier, but they should be informed and given enough time to complete important tasks, before the system locks them out.

Both approaches have pros and cons. A survey that is completely voluntary may not get enough responses, or may suffer from a response bias. A compulsory survey may frustrate some users, but will engage the entire user population.

Summative Evaluation Criteria

Reeves' evaluation criteria (1993) focus on the user interface of interactive instructional products, such as multimedia programs. As mentioned earlier, these criteria extend to LMS. If the user interface is not well designed, users will have little opportunity to learn from the program. Examples of a student survey instrument are included in Appendix 1 and key criteria used to define the survey questions (based on Reeves, 1993) are presented in this section. Continuing on the description of the earlier example, the sample questions are referred to a specific LMS system (Prometheus).

Ease of Use

"Ease of Use" is concerned with the perceived ease of a user interaction with the program. Figure 5 illustrates Reeves' dimension as ranging from the perception that the program is very difficult to use to one that is perceived as being very easy to use.

Navigation

"Navigation" is concerned with the perceived ability to move through the contents of an interactive program in an intentional manner. Figure 6 illustrates Reeves' dimension of interactive multimedia ranging from the perception that a program is difficult to navigate to one that is perceived as being easy to navigate. Possible options for navigation include evaluating the clarity of navigation icons.

Figure 5. "Ease of Use"

Example on a 5-point Likert scale:

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
I was able to learn Prometheus on my own ……..	❍	❍	❍	❍	❍	❍
Prometheus menus are intuitive……..	❍	❍	❍	❍	❍	❍

Figure 6. "Navigation"

Example on a 5-point Likert scale:

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
The navigation options in Prometheus are clear in each section……	❍	❍	❍	❍	❍	❍

Figure 7. "Cognitive Load"

Example on a 5-point Likert scale:

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
I do not need to remember several commands to use Prometheus……..……	❍	❍	❍	❍	❍	❍

Figure 8. "Mapping"

Example on a 5-point Likert scale:

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
Prometheus navigation layout is consistent……..….	❍	❍	❍	❍	❍	❍

Cognitive Load

The cognitive load is defined as any effort in addition to reading affects comprehension (i.e., navigation efforts or adjustment to the user interface). The higher the cognitive load the more difficult it is for the learner to comprehend. In terms of "cognitive load", Reeves states that the user interfaces can seem unmanageable (i.e., confusing) or easily manageable (see Figure 7).

Mapping

"Mapping" refers to the program's ability to track and graphically represent to the user the navigation path through the program. This is a critical variable because users frequently complain of being lost in an interactive program. Evaluations of interactive programs vary from containing no mapping function to an appropriately powerful mapping function (see Figure 8).

Screen Design

Screen design is a dimension of interactive programs that evaluates elements such as text (font layout and type), icons, graphics (placement), color (balance), and other visual aspects of interactive programs. "Screen design" ranges from substantial violations of the principles of screen design to general adherence of these principles (see Figure 9).

Knowledge Space Compatibility — [Content]

Refers to the compatibility of the product content with the layout of the learning space in the software application. When a novice user initiates a search for information in an interactive program, s/he could perceive the resulting information as compatible with his/her current knowledge space (see Figure 10). If the search results are not compatible, the application is weak in integrating content and technical features. This criterion is mostly applicable in interactive multimedia, where the content placement is static. In LMS systems, it can be used as "content" evaluation instruments.

Information Presentation

A dimension concerned with whether the information contained in an interactive program is presented in an understandable form. A well-designed user interface is ineffective if the information it is intended to present is incomprehensible to the user. (see Figure 11).

Media Integration

Deals with the question on whether the various media (text, graphics, audio, video) work together to form one cohesive program. The media integration dimension is defined as ranging from uncoordinated to coordinated (see Figure 12).

This criterion is not applicable in the context of LMS because the integration of media and their

Figure 9. "Screen Design"

Example on a 5-point Likert scale:

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
Prometheus enables me to easily interact with my instructor……	❍	❍	❍	❍	❍	❍

Figure 13. "Aesthetics"

Example on a 5-point Likert scale:

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
Prometheus screen design is pleasing…….	❍	❍	❍	❍	❍	❍

quality will be dependent primarily on the quality of the application that the individual content developers (faculty) will upload in the courseware. This criterion can be substituted with questions relative to "class interaction" and collaboration tools, key components of LMS tools that support interaction in multiple ways (audio, voice, and text interaction).

Aesthetics

"Aesthetics" deals with a subjective evaluation of the user of the screen layout ranging from displeasing to pleasing (see Figure 13).

Overall Functionality

"Overall Functionality" is related to the perceived utility of the program to achieve what its intended purposes are. It will include an evaluation of the factors that affect the perceived quality of the application. Figure 14 illustrates a dimension of the user interface of interactive programs that ranges from dysfunctional to highly functional.

Additional Criteria

Since Prometheus contains a series of features (course design tools and collaboration tools) that

Figure 14. "Overall Functionality"

Example on a 5-point

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
The technical quality of Prometheus is satisfactory..…	❍	❍	❍	❍	❍	❍

enable different types of class interaction, evaluation of the usefulness of the individual feature (as perceived by the user) is an important component of a complete summative evaluation. Questions evaluating user's perception of usefulness of the system will vary depending on whether the user is a student or a faculty member. The questions will cover each of the features available to the users, but will be accessed by the user only if s/he reported being familiar with or having used the feature at the beginning of the survey (see in Appendix 1, Syllabus, Outline, Projects, Lectures, Files, Email, Discussion, Chat, Utilities questions).

The deployment of the survey to a large population of LMS users can provide a better understanding of how LMS supports learning.

CONCLUSION

This paper presents a framework for the evaluation of LMS based on the criteria set forth by the literature on interactive multimedia. It claims that the convergence between multimedia and Web-based learning environments enables the extension of design guidelines to LMS. As in interactive instructional multimedia systems, an effective LMS strives for coherence and focuses on the reduction of the learner's cognitive load. LMS systems are currently consolidating, but variations and customizations still exist, especially in emerging open-source products representing lower cost solutions (Hall, 2005).

Evaluating LMS systems remains a key prerequisite and a first step for evaluating Web-based instruction effectiveness (Hills, 2003a). To address this assessment need, an evaluation protocol for LMS was proposed in this paper based on the integration of interactive multimedia and Web-evaluation criteria. Different types of evaluation and evaluation criteria were presented. Sample questions for each evaluation and strategies for the survey administration were also briefly discussed. These questions may constitute a useful reference tool for LMS evaluations. The survey questionnaire presented in the Appendix could be reviewed, changed, and integrated beyond the issues discussed in this paper. In any event, it could serve as a starting point for a serious effort to evaluate instructional software that has not yet been assessed by the majority of its users before, during, or after its integration in the curriculum. As Stoner (1996) and other authors (Carmean & Haefner, 2002) point out, *evaluation* is a key element of any proper curriculum implementation.

APPENDIX 1. SUMMATIVE EVALUATION QUESTIONNAIRE

Sample Student Survey

Please indicate how many courses you took on the LMS
_____(number)

Please indicate which features of the LMS your courses used (check all that apply)

- ❑ Syllabus
- ❑ Projects
- ❑ Lectures
- ❑ Files

- ❑ Email
- ❑ Discussion
- ❑ Chat

Please evaluate the LMS based on your overall experience with this Web-based courseware and your experience with the individual features used. Remember that this is an evaluation of the LMS as a software application, and **not** an evaluation of how well your instructor used the LMS.

Thank you for your time!

[Ease of Use]

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
The LMS menus are intuitive……..…….	❍	❍	❍	❍	❍	❍
If I have any problem, The LMS help menu provides useful information…..	❍	❍	❍	❍	❍	❍
I was able to learn The LMS features on my own……..	❍	❍	❍	❍	❍	❍
If I needed help, I had plenty of opportunities to learn additional The LMS features through:						
- The LMS team support ……...	❍	❍	❍	❍	❍	❍
- Support from my instructor ……	❍	❍	❍	❍	❍	❍
- Support from other students……..	❍	❍	❍	❍	❍	❍

Which other sections would be useful to you?

1. _____
2. _____
3. _____

[Screen Design]

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
The text layout on the screen makes it easy to read…..……..	❍	❍	❍	❍	❍	❍

[Content]

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
I can understand the meaning of all the instructions on any of the LMS page…….	❍	❍	❍	❍	❍	❍

Which instructions are unclear?

1. _____
2. _____
3. _____

[Information Presentation]

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
The LMS enables me to access class material in an organized way…….……	❍	❍	❍	❍	❍	❍

Please, indicate which type of documents you accessed on The LMS (check all that applies).

- ❑ Plain Text
- ❑ Word documents
- ❑ HTML files
- ❑ Video files
- ❑ Sound files
- ❑ PowerPoint presentations
- ❑ Portable document format (.PDF)
- ❑ Steaming media files (narrated PPT, audio, video)

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
The media (video, sound, graphics or text) used by my instructors on The LMS enabled me to better understand class information……	❍	❍	❍	❍	❍	❍

	Strongly Agree	Agree	Neither Agree Nor Disagree	Disagree	Strongly Disagree	Not Applicable
The LMS is a useful supplement in my courses…….……...	❍	❍	❍	❍	❍	❍

Which sections of The LMS gave you the most technical problems when accessing them?

1. _____
2. _____
3. _____

Which type of problems did you have?

1. _____
2. _____
3. _____

Have you used any other LMS?

- ❑ Yes (please specify_____)
- ❑ No

If yes, how does it compare with The LMS?

- ❑ Better
- ❑ The same
- ❑ Not as good

Section Specific Questions

[note: Questions in this section should appear in an online survey only if respondent selected that he/she uses the specific The LMS feature]

Kanchana Tandekar
Dakota State University, USA

INTRODUCTION

With the interactive capabilities on the Internet, business activities such as product display, order placing and payment are given a new facelift (Liu & Shrum, 2002). Consumer experience is also enhanced in an interactive environment (Haseman, Nuipolatoglu & Ramamurthy, 2002). A higher level of interactivity increases the perceived telepresence and the user's attitude towards a Web site (Coyle & Thorson, 2001). When it comes to learning, a higher level of interactivity improves learning and learner satisfaction (Liu & Schrum, 2002). While interactivity does not necessarily enable enhanced gain in user learning, it positively influences learners' attitudes (Haseman et al., 2002). Interactivity has been shown to engage users in multimedia systems (Dysart, 1998) to encourage revisits to a Web site (Dholakia et al., 2000), to increase satisfaction toward such systems (Rafaeli &Sudweeks, 1997), to enhance the visibility (as measured in number of referrals or backward links) of Web sites (Chen & Sockel, 2001) and to increase acceptance (Coupey, 1996).

BACKGROUND

According to the Merriam Webster dictionary, "interactivity" refers to 1) being mutually or reciprocally active, or 2) allowing two-way electronic communications (as between a person and a computer). However, within the scientific community, there is little consensus of what interactivity is, and the concept often means different things to different people (Dholakia, Zhao, Dholakia & Fortin, 2000; McMillan & Hwang,

2002). McMillan and Hwang (2002) suggest that interactivity can be conceptualized as a process, a set of features and user perception. Interactivity as a process focuses on activities such as interchange and responsiveness. Interactive features are made possible through the characteristics of multimedia systems. However, the most important aspect of interactivity lies in user perception of or experience with interactive features. Such an experience may very likely be a strong basis for future use intention.

Interactivity is considered a process-related construct, where communication messages in a sequence relate to each other (Rafaeli & Sudweeks, 1997). Ha and James (1998, p. 461) defined interactivity as "the extent to which the communicator and the audience respond to, or are willing to facilitate, each other's communication needs." Interactions between humans via media are also called mediated human interactions or computer-mediated communication (Heeter, 2000). Early studies tend to consider interactivity as a single construct, where multimedia systems vary in degrees of interactivity. Recent studies suggest that interactivity is a multi-dimensional construct.

As research continues to uncover the dynamic capabilities of multimedia systems, the definition of interactivity evolves to include aspects of hardware/software, processes during which the interactive features are used and user experience with interactive systems. Dholakia et al. (2000) suggest the following six interactivity dimensions: 1) user control, 2) responsiveness, 3) real-time interactions, 4) connectedness, 5) personalization/customization, and 6) playfulness. Similarly, Ha and James (1998) suggest five interactivity dimensions: 1) playfulness, 2) choice, 3) connectedness, 4) information collection, and 5) reciprocal communication.

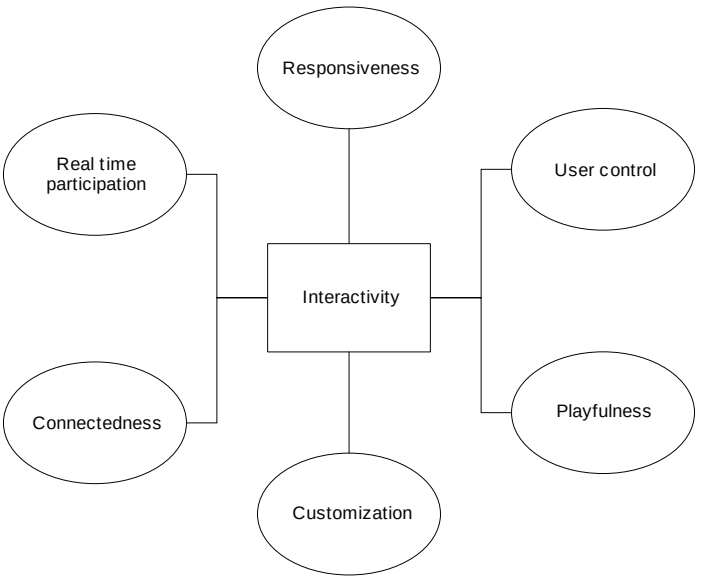
Within the context of multimedia systems, we view interactivity as a multidimensional concept referring to the nature of person-machine interaction, where the machine refers to a multimedia system. Figure 1 presents a conceptual framework, including interactivity dimensions defined as follows:

- **User control:** The extent to which an individual can choose the timing, content and sequence of communication with the system.
- **Responsiveness:** The relatedness of a response to earlier messages (Rafaeli & Sudweeks, 1997).
- **Real-time participation:** The speed with which communication takes place. This can range from instant communication (synchronous) to delayed response communication (asynchronous).
- **Connectedness:** The degree to which a user feels connected to the outside world through the multimedia system (Ha & James, 1998).
- **Personalization/Customization:** The degree to which information is tailored to meet the needs of individual users. For example, interactive multimedia learning systems must be able to accommodate different learning styles and capabilities.
- **Playfulness:** The entertainment value of the system; that is, entertainment value provided by interactive games or systems with entertaining features.

TECHNOLOGIES AND PRACTICES

The ubiquity of multimedia interactivity in general and on the Internet in particular is realized through the exponential growth in information technology. Specifically, the growth in computational power enabling ever-increasingly multimedia features coupled with advances in communication technologies and the Internet are pushing the interactivity frontier. Such technologies include, but are not limited to, a range of technologies, from the basic point and click to highly complex multimedia systems.

Figure 1. Interactivity as a multidimensional concept



In practice, and in their quest for interactivity, companies and organizations have resorted to a variety of techniques to encourage interactions in their systems. Table 1 provides a framework to map important multimedia/Web features from the existing literature to the six interactivity dimensions discussed in Figure 1. The goal of this framework is to offer practitioners a basis to evaluate interactivity in their multimedia systems. For example, a Web site designer may want to compare his or her design with popular Web sites in the same industry to measure if they offer a similar level of interactivity. Two important issues concerning the comparison include what interactive features are recommended for comparison and how to quantify interactivity features for comparison. The framework in Table 1 serves to answer the first question. One way to answer the second question involves simply counting the number of interactivity features in each of the interactivity dimensions. This counting technique is referred to as the interactivity index (II) and is frequently used by researchers to quantify interactivity. The quantified results, if measured consistently, can be used for longitudinal or cross-industry comparisons. Additionally, interactivity is examined with other constructs. Readers interested in empirical results focusing on the relationship between interactivity dimensions and other constructs are referred to the cited references, such as Ha and James (1998), Dholakia et al. (2000); Chen and Sockel (2001); McMillan and Hwang (2002); Burgoon, Bonito, Ramirez, Dunbar, Kam and Fischer (2002); and Chen and Yen (2004).

CURRENT RESEARCH

Interactivity is an active area of research that spans a number of research fields, including computer science, human computer interaction (HCI), information systems, education, marketing, advertisement and communication. A comprehensive review of the literature is beyond the scope of this article. Instead, we focus our attention on current research effort as it pertains to multimedia interactivity on the Internet, with a particular emphasis on education, advertisement and marketing.

Table 1. A framework of mapping multimedia/Web features to interactivity dimensions

Interactivity dimensions	Multimedia/Web features	
User control	• Alternative options for site navigation • Linear interactivity, where the user is able to move (forward or backwards) through a sequence of contents	• Object interactivity (proactive inquiry) where objects (buttons, people or things) are activated by using a pointing device.
Responsiveness	• Context-sensitive help • Search engine within the site	• Dynamic Q&A (questions and responses adapt to user inputs)
Real-time participation	• Chat rooms • Video conferencing	• E-mail • Toll-free number
Connectedness	• Video clips • Site tour	• Audio clips • Product demonstration
Personalization/ Customization	• Site customization • Bilingual site design	• Customization to accommodate browser differences
Playfulness	• Games • Software downloads • Visual simulation	• Online Q&A • Browser plug-ins (e.g., flash, macromedia, etc.)

Current research on multimedia interactivity predominantly focuses on conceptual issues related to the definition and measurement of interactivity, evaluation of interactive multimedia systems, design issues and applications of interactive multimedia systems. Regarding conceptual issues, Kirch (1997) questions the decision cycle model, which is the received theory in human computer interaction, and discusses additional ways of interacting with multimedia systems; while Ohl (2001) questions the adequacy of current definitions of interactivity in the context of educational systems.

Haseman, Polatoglu and Ramamurthy (2002) found that interactivity leads to favorable attitude formation but not so much to improved learning outcomes. There had been no evidence to prove that interactivity influences user achievement. Liu and Shrum (2002) propose that higher levels of interactivity create a cognitively involving experience and can enhance user satisfaction and learning.

Concerning design considerations, Robinson (2004) identifies interactivity as one of eight principles for the design of multimedia material. Examples of case studies and applications reported in the literature include Abidin and Razak's (2003) presentation of Malay folklore using interactive multimedia. Table 2 lists research contributions pertaining primarily to multimedia interactivity.

Internet interactivity has also attracted interest in areas such as the measurement of interactivity, evaluation of the effectiveness of interactivity and design considerations for Internet-interactive Web sites. For example, Paul (2001) analyzed the content of 64 disaster relief Web sites and found that most sites had a moderate level of interactivity but were not very responsive to their users. A study conducted by Ha and James (1998) attempted to deconstruct the meaning of interactivity, and then reported the results of a content analysis that examined the interactivity levels of business Web sites. Their findings suggest that five interactivity dimensions are possible, with the reciprocal

Table 2. Current research focusing primarily on multimedia interactivity

Research focus	Conceptual	Evaluation	Design	Application
Research work	Ohl (2001), Massey (2000)	Karayanni et al. (2003), Haseman et al. (2002), Liu and Shrum (2002), Ellis (2001), Moreno (2001), Mayer (2001)	Robinson (2004), Zhang et al. (2003), Trindade et al. (2002)	Adibin et al. (2003), Hou et al. (2002), Paustian (2001)

communication dimension being the most popular dimension. In an effort to explore the relationship between Ha and James' (1998) interactivity dimensions and the quality of Web sites, Chen and Yen (2004) suggested that reciprocal communication, connectedness and playfulness are the most salient dimensions of interactivity that influence design quality. Moreover, Lin and Jeffres (2001) performed a content analysis of 422 Web sites associated with local newspapers, radio stations and television stations in 25 of the largest metro markets in the United States. Results show that each medium has a relatively distinctive content emphasis, while each attempts to utilize its Web site to maximize institutional goals.

According to Burgoon et al. (2002), computer mediated communication may even be better than non-mediated or face-to-face interaction, even though face-to-face is considered easier. The study also points out that distal communication, mediation and loss of non-verbal cues do not necessarily result in worse decision quality or influence, but may, in fact, enhance performance in some cases.

Addressing design considerations, McMillan (2000) identified 13 desirable features that an interactive Web site should possess in order to be interactive. These features include: e-mail links, hyperlinks, registration forms, survey forms, chat rooms, bulletin boards, search engines, games, banners, pop-up ads, frames and so forth. High levels of vividness help create more enduring attitudes (Coyle & Thorson, 2001). A study by Bucy, Lang, Potter and Grabe (1999) found presence of advertising in more than half of the Web pages sampled. It also suggests a possible relationship between Web site traffic and the amount of asynchronous interactive elements like text links, picture links, e-mail links, survey forms and so forth. Features most commonly used on the surveyed Web sites were frames, logos and a white background color.

FUTURE TRENDS

Long-term impacts of interactivity should be studied on learning, attitudes and user outcomes. To study learning behavior of students, their knowledge should be tested twice; once at first and then after a few days or weeks for absorption/retention (Haseman et al., 2002). Coyle and Thorson (2001, p. 76) suggested to "focus on additional validation of how new media can approximate a more real experience than traditional media." One way to do this would be to replicate previous findings dealing with direct or indirect experience. Will more interactive and more vivid systems provide more direct experience than less interactive, less vivid systems? Also, future research should focus on testing specific tools to understand how their interactivity characteristics improve or degrade the quality of user tasks at hand.

The current literature appears to lack consensus on the dimensionality of interactivity. Inconsistent labeling or defining the scope of interactivity dimensions exists in several studies; for example, playfulness and connectedness ap-

pear to be included in both Dholakia et al. (2000) and Ha and James (1998), but Dholakia et al.'s personalization/customization dimension was embedded in Ha and James' choice dimension. Furthermore, much of interactivity research employed only qualitative assessment of interactivity dimensions (such as Heeter, 2000), suggesting future avenues for empirical validations and perhaps further refinement.

Despite disagreements in interactivity dimensions, user interactivity needs may vary across time, user characteristics, use contexts and peer influence. A suggestion for further research is to take into account the factors that drive or influence interactivity needs in different use contexts. Another suggestion is to study whether user perception depends on the emotional, mental and physical state of people; that is, their personality and to what extent or degree it depends on these characteristics and how these can be altered to improve the overall user perception.

CONCLUSION

Multimedia interactivity on the Internet – while considered as "hype" by some – is here to stay. Recent technological advancements in hardware, software and networks have enabled the development of highly interactive multimedia systems. Studying interactivity and its effects on target users certainly impact business values. Research pertaining to interactivity spans a number of disciplines, including computer science, information science, education, communication, marketing and advertisement. Such research addressed a variety of issues, ranging from attempting to define and quantify interactivity to evaluating interactive multimedia systems in various application domains, to designing such systems. Nevertheless, a number of research issues warrant further consideration, particularly as it pertains to quantifying and evaluating interactive multimedia systems.

In effect, the critical issues discussed in this chapter offer many implications to businesses, governments and educational institutions. With regard to businesses, multimedia interactive systems will continue to play a major role in marketing and advertisement. Interactive virtual real estate tours are already impacting the real estate industries. Interactive multimedia instruction is changing the way companies and universities alike provide educational services to their constituents. From physics and engineering to biology and history, interactive multimedia systems are re-shaping education.

KEY TERMS

Computer-Mediated Communication (CMC): Refers to the communication that takes place between two entities through a computer, as opposed to face-to-face interaction that takes place between two persons present at the same time in the same place. The two communicating entities in CMC may or may not be present simultaneously.

Machine Interactivity: Interactivity resulted from human-to-machine or machine-to-machine communications. Typically, the later form is of less interest to most human-computer studies.

Reach: To get users to visit a Web site for the first time. It can be measured in terms of unique visitors to a Web site.

Reciprocal Communication: Communication that involves two or more (human or non-human) participants. The direction of communication may be two way or more. However, this type of communication does not necessarily suggest that participants communicate in any preset order.

Stickiness: To make people stay at a particular Web site. It can be measured by time spent by the user per visit.

Synchronicity: It refers to the spontaneity of feedback received by a user in the communication process. The faster the received response, the more synchronous is the communication.

Telepresence: Defined as the feeling of being fully present at a remote location from one's own physical location. Telepresence creates a virtual or simulated environment of the real experience.

Two-Way Communication: Communication involving two participants; either both of the participants can be humans or it could be a human-machine interaction. It does not necessarily take into account previous messages.

Chapter 1.9
Multimedia Content Adaptation

David Knight
Brunel University, UK

Marios C. Angelides
Brunel University, UK

INTRODUCTION

The previous decade has witnessed a wealth of advancements and trends in the field of communications and subsequently, multimedia access. Four main developments from the last few years have opened up the prospect for ubiquitous multimedia consumption: wireless communications and mobility, standardised multimedia content, interactive versus passive consumption and the Internet and the World Wide Web. While individual and isolated developments have produced modest boosts to this existing state of affairs, their combination and cross-fertilisation have resulted in today's complex but exciting landscape. In particular, we are beginning to see delivery of all types of data for all types of users in all types of conditions (Pereira & Burnett, 2003).

Compression, transport, and multimedia description are examples of individual technologies that are improving all the time. However, the lack of interoperable solutions across these spaces is holding back the deployment of advanced multimedia packaging and distribution applications. To enable transparent access to multimedia content, it is essential to have available not only the description of the content but also a description of its format and of the usage environment in order that content adaptation may be performed to provide the end-user with the best content experience for the content requested with the conditions available (Vetro, 2003).

In the following sections, we will look at the background of multimedia content adaptation, why do we require it and why are present solutions not adequate. We then go onto the main focus of the article, which describes the main themes of modern multimedia content adaptation, such as present day work that defines the area and overviews and descriptions of techniques used. We then look at what this research will lead to in the future and what we can expect in years to come. Finally, we conclude this article by reviewing what has been discussed.

BACKGROUND

More and more digital audio-visual content is now available online. Also more access networks are available for the same network different devices (with different resources) that are being introduced in the marketplace. Structured multimedia content (even if that structure is still limited) increasingly needs to be accessed from a diverse set of networks and terminals. The latter range (with increasing diversity) from gigabit Ethernet-connected workstations and Internet-enabled TV sets to mobile video-enabled terminals (Figure 1) (Pereira & Burnett, 2003).

Adaptation is becoming an increasingly important tool for resource and media management in distributed multimedia systems. Best-effort scheduling and worst-case reservation of resources are two extreme cases, neither of them well-suited to cope with large-scale, dynamic multimedia systems. The middle course can be met by a system that dynamically adapts its data, resource requirements, and processing components to achieve user satisfaction. Nevertheless, there is no agreement about questions concerning where, when, what and who should adapt (Bormans et al., 2003).

On deploying an adaptation technique, a lot of considerations have to be done with respect to how to realise the mechanism. Principally, it is always useful to make the technique as simple as possible, i.e., not to change too many layers in the application hierarchy. Changes of the system layer or the network layer are usually always quite problematic because deployment is rather difficult. Generally, one cannot say that adaptation technique *X* is the best and *Y* is the worst, as it highly depends on the application area.

The variety of delivery mechanisms to those terminals is also growing and currently these include satellite, radio broadcasting, cable, mobile, and copper using xDSL. At the end of the distribution path are the users, with different devices, preferences, locations, environments, needs, and possibly disabilities.

In addition the processing of the content to provide the best user experience may be performed at one location or distributed over various locations. The candidate locations are: the content server(s), any processing server(s) in the network, and the consumption terminal(s). The choice of the processing location(s) may be determined by several factors: transmission bandwidth, storage and computational capacity, acceptable latency, acceptable costs, and privacy and rights issues (see Figure 2).

Present adaptation technologies concerning content adaptation mainly focus on the adaptation

Figure 1. Different terminals access multimedia content through different networks

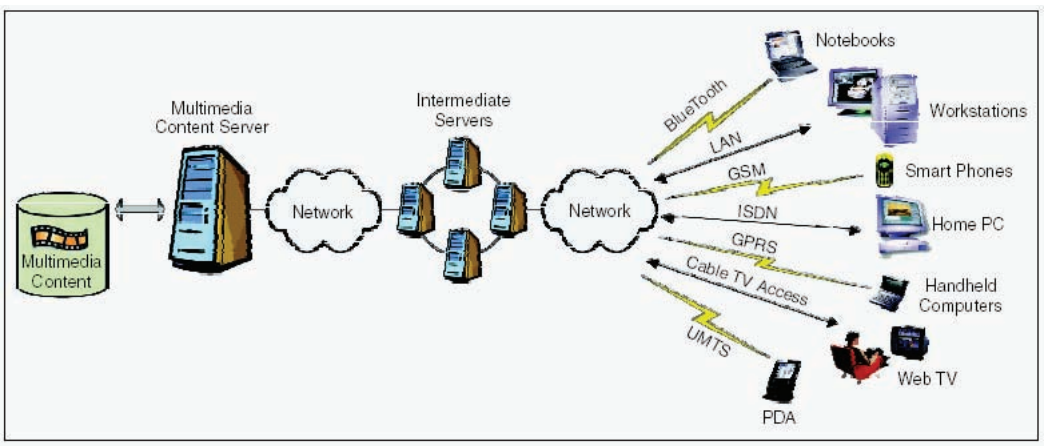

Figure 2. Adaptation may be performed at different places

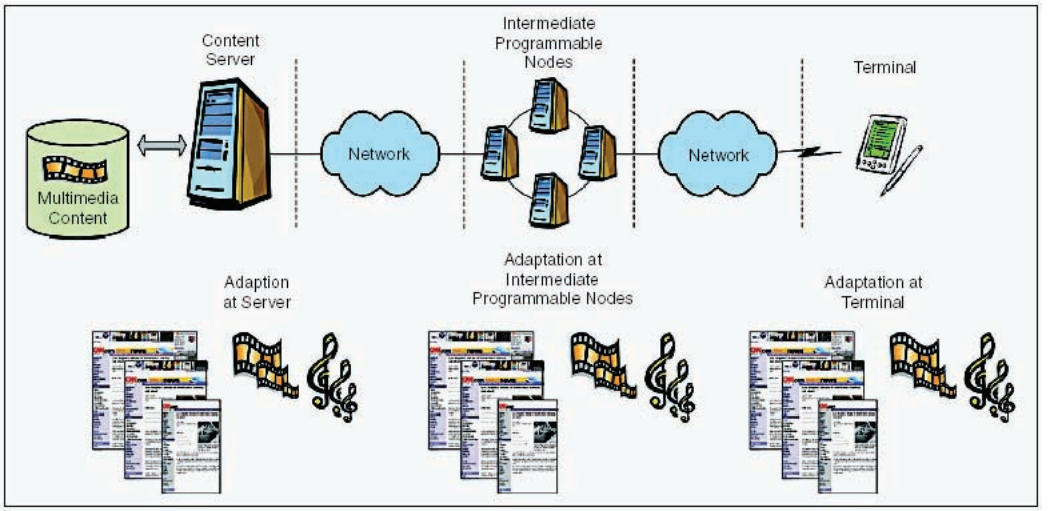

of text documents. Therefore, one text document will be adapted on demand to the capabilities of different devices or applications. To fulfill this functionality the structure of the content must be separated from its presentation, i.e., the source document is structured using XML (Extensible Markup Language) and then dynamically processed to generate a presentation tailored to the available resources. One possible use case scenario will be to present the same information either on a standard Web browser or a WAP browser.

Efficient adaptation requires that the participating components know from each other and take advantage of adaptation steps done by other components, which needs standardised media, metadata, and communication. Several standardisation bodies (W3C, MPEG, and WAP) have already been established or are currently under development, which have recognised the need to create a framework that facilitates the efficient adaptation of content to the constraints and preferences of the receiving end.

MPEG-7 (ISO/IEC 15938-5:2002) provides tools for content description, whilst capability description and negotiation is provided for with CC/PP (Composite Capabilities/Preference Profiles, 2003) and UAProf (WAG User Agent Profile, 2001). MPEG-21 (ISO/IEC JTC 1/SC 29/WG 11), the "multimedia framework" includes Digital Item Adaptation (DIA), which enables standard communication of dynamic adaptation of both media resources and meta-data, enabling negotiation of device characteristics and QoS parameters. (Böszörményi et al., 2002)

In this section, the reasons for the need for interoperable and efficient multimedia content adaptation have been introduced. A number of standards groups (such as W3C, MPEG and WAP) that facilitate multimedia content adaptation by concentrating on the adaptation of associated XML-type documents have also been mentioned. The next section delves into the different technologies that help make up this exciting field.

MAIN THRUST OF THE CHAPTER

In this section we will look at the main themes found in multimedia content adaptation. We start with a look at a multimedia content adaptation architecture, a discussion on the present state of affairs regarding scalable coding and transcoding,

an analysis of the effect the actual location point the adaptation takes place and a brief summary of the relevance of user profiling.

Multimedia Content Adaptation Architecture

The networking access paradigm known as Universal Multimedia Access (UMA) refers to the way in which multimedia data can be accessed by a large number of users/clients to view any desired video stream anytime and from anywhere. In the UMA framework, multimedia information is accessed from the network depending on the following three parameters: channel characteristics, device capabilities, and user preference.

Figure 3 gives an example of different presentations (to suit different capabilities such as formats, devices, networks, and user interests) of the same information.

One option for UMA is to provide different variations of the content with different quality, bit rate, media modality (e.g., audio to text), etc. The problem with this option is that it is not too efficient from the viewpoint of variation generations and storage space. On the other hand, real-time transformation of any content implies some delay for the processing and a lot of computing resources at the server (or proxy server) side. Pursuing either of these two options assumes the use of an adaptation engine. Figure 4 gives a bird's eye-view of such an adaptation engine architecture that is applicable to the adaptation of any type of content.

The architecture consists of an adaptation engine that can be located on the server, an intermediate network device such as a gateway, router, or proxy, or even on the client. This engine comprises of two logical engine modules, the adaptation decision engine and the resource adaptation engine. The adaptation decision engine receives the metadata information about the available content (context, format, and adaptation options) from the resource repository and the constraints (terminal and network capabilities, user characteristics, and preferences) from the receiving side. If there are multiple versions of the content pre-stored in the repository and one of these versions matches the constraints, then this version is selected, retrieved, and sent to the end user. However, if the available resource does not match the constraints, but can be adapted, then the adaptation decision engine

Figure 3. Different presentations of the same information

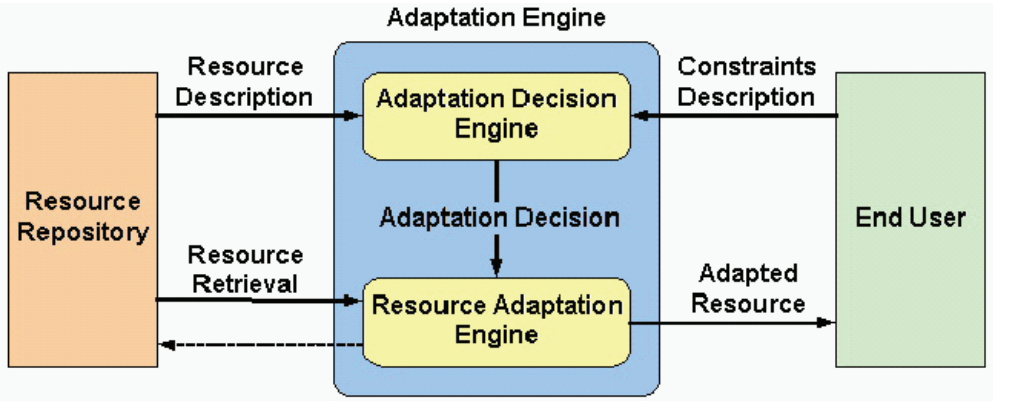
Figure 4. Bird's-eye view of an adaptation engine architecture



determines the optimal adaptation for the given constraints and passes this decision to the resource adaptation engine. The resource adaptation engine retrieves the resource from the repository, applies the selected adaptation, and sends the adapted resource to the end user.

Constraints can be grouped into four broad categories: user and natural environment characteristics, terminal capabilities, and network characteristics. The terminal and network constraints will set an upper bound on the resources that can be transmitted over the network and rendered by the terminal. Information like the network's maximum bandwidth, delay and jitter, or the terminal's resolution, buffer size, and processing power, will help the adaptation engine determine the optimal version of the resource for the given network and terminal device. As the user is the actual consumer (and judge) of the resource, user-related information, including user preferences, user demographics, usage history and natural environment, is equally important in deciding which resource should be delivered to the terminal.

The adaptation engine needs to have sufficient information about the context and the format of the multimedia resources in order to make a decision whether the resource is suitable for the user or how it should be adapted in order to offer the user the optimal context and quality. The description should therefore include information on the resource type, semantics, available adaptation options, and characteristics of the adapted versions of the resource (Panis et al., 2003).

Scalable Coding

If content is scalable, then adapting content may be done using scalable coding. This removes or alters parts of resources in such a way as to reduce their quality in order to satisfy the receiver's capabilities and needs. Currently available scaling options depend on the coding format to be used. The Holy Grail of scalable video coding is to encode the video once, and then by simply truncating certain layers or bits from the original stream, lower qualities, spatial resolutions, and/or temporal resolutions could be obtained (Vetro, 2003).

Current scalable coding schemes fall short of this goal. MPEG-4 is currently the content representation standard where the widest range of scalability mechanisms is available, notably in terms of data types, granularities, and scalability domains (Pereira & Ebrahimi, 2002).

Transcoding

This is another more complex option that typically refers to transforming the resource from one

coding format into another one, i.e., decoding the resource and encoding the resource using another codec (e.g., transcode an MPEG-2 video to an MPEG-1 video). According to Sun et al. (2003), the key design goals of transcoding are to maintain the video quality during the transcoding process and to keep complexity as low as possible. Cavallaro et al. (2003) identify three main approaches to video transcoding: content-blind transcoding, semantic transcoding, and description-based transcoding:

- **Content-blind transcoding** does not perform any semantic analysis of the content prior to conversion. The choice of the output format is determined by network and appliance constraints, independent of the video content (i.e., independent of the way humans perceive visual information). The three main content-blind transcoding categories are spatial conversion, temporal conversion, and colour-depth reduction.
- **Semantic (or intramedia) transcoding** analyses the video content prior to conversion. An example of such analysis is the separation of the video content into two classes of interest, namely foreground and background. Once this separation has been accomplished, the two classes can be coded differently to better accommodate the way humans perceive visual information, given the available network and device capabilities.
- **Description-based (or intermedia) transcoding** transforms the foreground objects extracted through semantic segmentation into quantitative descriptors. These quantitative descriptors are transmitted instead of the video content itself. In this specific case, video is transformed into descriptors so as to produce a textual output from the input video. Such textual output can be used not only for transcoding, but also for annotating the video content and for translating the visual content into speech for visually impaired users. This transformation is also referred to as cross-media adaptation.

Location of Adaptation

As well as the technologies used, the location used for multimedia content adaptation needs to be addressed. Resource delivery and adaptation can be sender-driven, receiver-driven, or network-driven.

Sender-driven proceeds to adapt resources at the sender/server node depending on the terminal and/or network capabilities received beforehand. After successful adaptation the sender transmits the adapted version of the resource to the receiver. This action requires a serious amount of computational power at the server node and goes at the expense of latency between the receiver's request and the server's delivery.

In contrast, the receiver-driven approach decides what and how to adapt at the terminal side although the real adaptation could take place somewhere else, e.g., on a proxy node. Adaptation directly at the end node could fail due to insufficient capabilities. Additionally network bandwidth will be wasted, too. Nevertheless, adaptation on terminal devices should not be strictly excluded.

The pure network-driven approach is transparent where the network, i.e., the transport system, is responsible for adaptation only. Typical use case scenarios will cover all kind of adaptation approaches described so far, i.e., resource adaptability along the delivery chain, from resource provider to resource consumer. A high-performance server node will provide some kind of preprocessing in order to facilitate easy adaptation along the delivery chain across a wide range of network and terminal devices. Network nodes such as routers or gateways will then perform so-called light-weight adaptations using segment dropping or minor editing techniques whereas proxy nodes could utilise more complex adaptation techniques.

Such complex adaptation techniques include not only scaling but also transcoding and cross-media. An adaptive terminal device could perform adjustments due to user and/or usage preferences. The complexity of these adaptations to be done in terminal devices depends on its capabilities, e.g., display resolution, computational power, local storage capacity, and buffer size.

User Profiling

In order for the personalisation and adaptation of multimedia content to take place, the users' preferences, interests, usage, and environment need to be described and modelled. This is a fundamental realisation for the design of any system that aims to aid the users while navigating through large volumes of audio-visual data. The expectation is that by making use of certain aspects of the user model, one can improve the efficacy of the system and further help the user (Kobsa et al., 2001).

This section described the components needed to make up a multimedia content adaptation architecture: transcoding, scalable coding, location of adaptation, and user profiling. The next section discusses the future of multimedia content adaptation by looking at UMA, transcoding, and scalability, specifically.

FUTURE TRENDS

The major problem for multimedia content adaptation is to fix the mismatch between the content formats, the conditions of transmission networks, and the capability of receiving terminals. A mechanism for adaptation needs to be created for this purpose.

Scalable coding and transcoding are both assisting in this. It can be seen that scalable coding and transcoding should not be viewed as opposing or competing technologies. Instead, they are technologies that meet different needs regarding multimedia content adaptation and it is likely that they will coexist.

Looking to the future of video transcoding, there are still quite a number of topics that require further study. One problem is finding an optimal transcoding strategy. Given several transcoding operations that would satisfy given constraints, a means for deciding the best one in a dynamic way has yet to be determined. Another topic is the transcoding of encrypted bit streams. The problems associated with the transcoding of encrypted bit streams include breaches in security by decrypting and re-encrypting within the network, as well as computational issues (Vetro, 2003).

The inherent problem with cross-media (description-based) adaptation is in preserving the intended semantics. What are required are not the blindfolded exchange of media elements and fragments, but their substitution by semantically equivalent alternatives. Unfortunately, current multimedia authoring tools provide little support for producing annotated multimedia presentations. Richly annotated multimedia content, created using document-oriented standards, such as MPEG-7 and MPEG-21 DIA, will help facilitate sophisticated cross-modal adaptation in the future.

For the implementation of UMA, "universal," scalable, video-coding techniques are essential components. Enhancements to existing video-coding schemes, such as MPEG-4 FGS (Fine-Granular-Scalability) and entirely new schemes will help drive the UMA ideal. More efficient FGS-encoders, tests on the visual impact of variability and more improved error resilient techniques are improvements that can be made to scalable coding schemes.

While some technologies such as content scalability and transcoding are fairly well established, there are still vital technologies missing for a complete multimedia content adaptation system vision. Many of these technologies are directly related to particular usage environments. While multimedia adaptation for improved experiences

is typically thought of in the context of more constrained environments (e.g., mobile terminals and networks), it is also possible that the content has to be adapted to more sophisticated environments, e.g., with three-dimensional (3-D) capabilities. Whether the adaptation processing is to be performed at the server, at the terminal, or partially at both, is something that may have to be determined case–by-case, depending on such criteria as computational power, bandwidth, interfacing conditions, and privacy issues.

CONCLUSION

The development and use of distributed multimedia applications is growing rapidly. The subsequent desire for multimedia content adaptation is leading to new demands on transcoding, scaling, and, more generally, adaptation technologies. Metadata-based standards, such as MPEG-7 and MPEG-21, which describe the semantics, structure, and the playback environment for multimedia content are breakthroughs in this area because they can assist more intelligent adaptation than has previously been possible.

A prerequisite for efficient adaptation of multimedia information is a careful analysis of the properties of different media types. Video, voice, images, and text require different adaptation algorithms. The complex nature of multimedia makes the adaptation difficult to design and implement. By mixing intelligence that combines the requirements and semantic (content) information with low-level processing, the dream of UMA could be closer than we envision.

KEY TERMS

Bit Stream: The actual data stream, which is the transmission of characters at a fixed rate of speed. No stop and start elements are used, and there are no pauses between bits of data in the stream.

Content Scalability: The removal or alteration of certain subsets of the total coded bit stream to satisfy the usage environment, whilst providing a useful representation of the original content.

Cross-Media Adaptation: Conversion of one multimedia format into another one, e.g., video to image or image to text.

Multimedia Content Adaptation: The process of adapting a multimedia resource to the usage environment. The following factors make up this usage environment: users preferences, device, network, natural environment, session mobility, adaptation QoS, and resource adaptability.

Transcoding: The process of changing one multimedia object format into another.

UMA: How users can access the same media resources with different terminal equipment and preferences.

User Modelling: In the context of adaptation, the describing/modelling of the users preferences, interests, usage, and environment.

Michael Mathew
Monash University, Australia

ABSTRACT

In order to meet the ever increasing demand by people using mobile technology and its associated services based on multimedia elements in addition to voice, mobile communication technologies has since evolved from analog to digital and 1G to 4G. This chapter presents a contemporary review of all generations of mobile communication technologies, including their standards. 1G to 3G mobile communication technologies are mainly optimised for voice communication, using circuit switched networks. To provide high transmission mobile services at low cost in all levels of networks—personal, home, and cellular—it is imminent to exploit the merits of all existing technologies such as Bluetooth, WLAN, and HiperLAN, and use IP as a backbone network in 4G mobile communication standards. The key research challenges for mobile terminals, systems, and services for 4G networks are also presented in this chapter.

INTRODUCTION

Multimedia refers to the combination of different types of media elements such as text, audio, image, and video in a digital form which is represented and manipulated by a single electronic device or a single computing platform such as a PC (Chapman & Chapman, 2000). Interactive multimedia provides the interaction facility with users so they can access and exit the system as they wish.

Text comprises a string of alphabets from a particular character set. Image is a visual object

consisting of a rectangular pattern of dots or primitive elements—lines, curves, circles, and so on (Halsall, 2001). Examples of images are computer generated graphics and digitized documents, pictures, and graphic arts. Images could be either 2D or 3D. Both text and images are inherently in a digital form. Bandwidth requirement for the transmission of text and image is less than that of high-fidelity audio and video. Audio is generally represented by the amplitude of sound waves, which includes low-fidelity speech during telephonic conversation, high-fidelity CD-quality audio and surround sound.

Video is a sequence of still images or frames displayed in a repaid succession so the human eye cannot pick up their transitions, and hence it creates an illusion of motion. Examples of video include movies, short films, and animation. Both audio and video are continuous time varying signals and analog in nature. For an integrated representation, all media elements must be represented in digital form.

With the rapid growth of the Internet, multimodal representation and interactive facilities of multimedia-based systems, the necessity of required information, accurate presentation, and quick perception, the applications of multimedia are burgeoning in every aspect of human life ranging from home, education, medicine, e-commerce and m-commerce, to airport security. The demands of these applications are met with the different types of multimedia-based services that are a combination of a number of media elements, but not limited to—interactive television (text, audio, and video), video phone and conference (speech and video), computer supported cooperative working (text and images), on-line education (text, images, audio and video), multimedia electronic mail (text, images, and audio, for example), e-commerce (text, images, audio, and video) and Web and Mobile TV (text, audio, and video) (Halsall, 2001).

Due to the inherent high data rates, especially for audio and video, a number of compression techniques for both audio and video have been introduced, which has made it possible to transmit the video over broadband networks. Even with the advancement of compression technologies, the usual bit rate for a speech signal is 64kbps, while it is 384Kbps for low quality video, and up to 2Mbps for high quality video (Sawada, Tani, Miki, & Maruyama, 1998). The tentative bandwidth requirement for the future networks for enhanced-reality multimedia communications are projected from 1Mbps to 30Gbps for 3D audio and 3D video (Ohya & Miki, 2005).

Requirements for an on-demand real-time telephone network access for various purposes such as business, education, and social, cultural, and psychological factors, the scope of technology has been expanded from land-base fixed communications, to wireless and mobile multimedia communications. With the advent of wireless and mobile networks, people now have the opportunity to communicate with anybody, anywhere, and at any time. The number of mobile users is rapidly increasing all over the world (Rao & Mendoza, 2005; Salzman, Palen, & Harper, 2001). It is estimated the number of worldwide mobile users will be 1.87 billion by the end of 2007 (Garfield, 2004).

To meet the ever-increasing consumer demands and make the multimedia-based services as appealing as possible, the mobile networks have evolved from 1G to 4G. 1G mobile networks were commercially released in 1980. Examples of a 1G network include Advanced Mobile Phone Service (AMPS) and Total Access Communication System (TACS). An AMP is in American roaming, while TACS is European roaming. These are based on cellular analog technology. They were initially provided voice service at a rate of 2.4 kbps (Casal, Schoute, & Prasad, 1999), which had been extended to 19 kbps with the introduction of Cellular Digital Packet Data (CDPD) in the bedrock of 1G analog cellular networks for providing digital data service. Since all of these 1G networks are analog broadcasting, they are

not secured and hence vulnerable to intercepting calls through a radio frequency scanner (McCullough, 2004).

For providing secured communication, higher transmission of up to 64 kbps, better quality of signal, as well as meeting ever increasing demand from users, 1G analog mobile standards evolved into 2G digital communication technologies around 1990. 2G mobile communication standards include Global System for Mobile Communication (GSM), Digital AMPS (D-AMPS), cdmaOne (IS-95), Personal Digital Cellular (PDC). Later, some of 2G standards have been enhanced to provide higher bit rate transmission up to 384 kbps, and data services including the Internet, which is known as 2.5G. An example of such an enhancement of GSM is a circuit switched network called GPRS, which is a packet switched network, and provides Internet facilities for mobile users (Andersson, 2001; Wikipedia, 2006).

To increase the capacity up to broadband communication, that is, 2 Mbps, and hence the number of subscribers, the specification of the 3G standard is outlined by IMT2000 considering the hierarchical cell structure, global roaming, and dynamic allocation of a radio frequency from a pool. This enables 3G to provide services such as fast Internet browsing and mobile multimedia communications—mobile TV, video phone, and video conferencing. Despite 3G being adopted as a current standard, its full-fledged implementation is being delayed because of the problems for the introduction of new hardware and dynamic frequency allocation—consequently making 3G obsolete and introducing 4G.

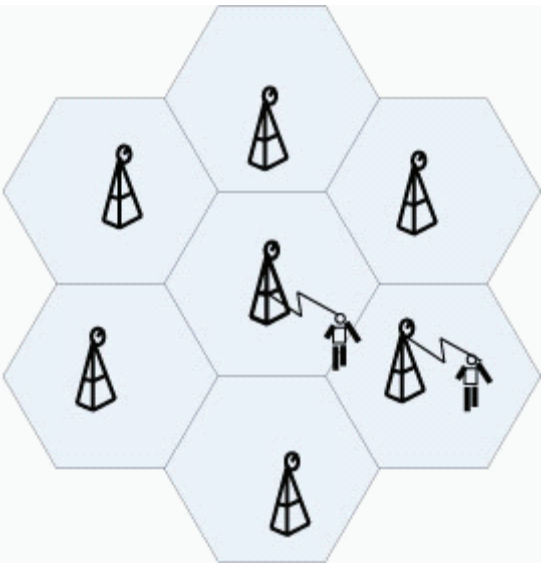
It is expected 4G mobile communication networks will be commercially available in the market within 2010. Its main purpose is to provide high transmission of multimedia data up to 1Gbps based on IP-core networks (Hui & Yeung, 2003; Ohya & Miki, 2005). It will consist of heterogeneous state-of-the-art technologies ranging from ad-hoc sensor networks, to intelligent home appliances, and to provide cutting-edge services including ubiquitous, reality, and personalised communications.

GENERATIONS OF MOBILE MULTIMEDIA NETWORKS

The first mobile telephone standard was introduced by AT&T in St. Louis, Missouri, USA, and was available for public users of this city in 1946. The mobile system (a radio telephone network) was installed on the top of a building in the metropolitan area. All users received their services through this system with a mobile operator, who routed both incoming and outgoing calls to the intended recipients. A high powered radio-based transmitter was used to cover the required area. However, the number of frequencies and hence the channels were very limited. It was difficult to have a dial tone and users had problems to complete calls. The system operated in a half-duplex communication mode, that is, one way communication at a time based on push-to-talk communication mode. The mobile set was very heavy and bulky.

An example of one of the initial mobile telephone standards is the Mobile Telephone Systems (MMT). Because of the demand beyond the capacity and previously mentioned disadvantages, the traditional analog mobile telephone technology was upgraded in 1960, and an Improved Mobile Telephone Service (IMTS) was introduced, which eliminates the push-to-talk mode by providing direct access to the dial telephone networks and full-duplex transmission. In this standard, the usage of high powered radio at 200 watts created interference up to 100 miles, which allowed limited available channel capacity and frequency reuse. The limited channel capacity and excessive demands for communication at anytime from anywhere brought the birth of cellular mobile telephone networks in 1974 (Bates, 1995). In cellular technology, a coverage area is divided into small hexagonal zones known as cells shown in Figure 1.

Figure 1. Organization of hexagonal cells for a coverage area



Each cell has its base station consisting of a transmitter and two receivers per channel, a base station controller, an antenna system, and a data link to the base station controller or cellular office. The average size of a cell is three to five miles, which eventually resulted in a far less coverage area compared with non-cellular technology for a mobile phone, and hence reduced the required transmission power and interference between the neighbouring cells significantly. This made it possible to reuse the frequency and to develop a protection zone in the form of clustering of frequencies for a particular cell against the interference of its neighbouring cells, which paved the way of increasing the channel capacity of a cell, and hence the mobile communication networks. In order to meet the ever increasing demand for communication at anytime for anywhere using any technology, the cellular mobile communication technology has evolved so far into four generations shown in Table 1.

The description of each generation, including their related network standards are described in the following section.

First Generation (1G) Cellular Mobile Networks

Because of the increasing demands of users, it was necessary to increase the capacity and mobility of mobile telephone users. To meet this demand, the analog cellular technologies were designed and completed by AT&T in 1974 and commercialised in the 1980s. This analog service is still available around the world and played a vital role to increase the popularity of mobile phone and the mobile users at 30 to 50% per year, which contributed to approximately 20 million users within 1990 (IFC, 2005). Examples of 1G generation mobile cellular networks are Advanced Mobile Phone Service (AMPS), Total Access Communication System (TACS), and Nordic Mobile Telephone (NMT).

Advanced Mobile Phone Service (AMPS)

AMPS is the first analog cellular system, which was designed and developed by AT&T in the

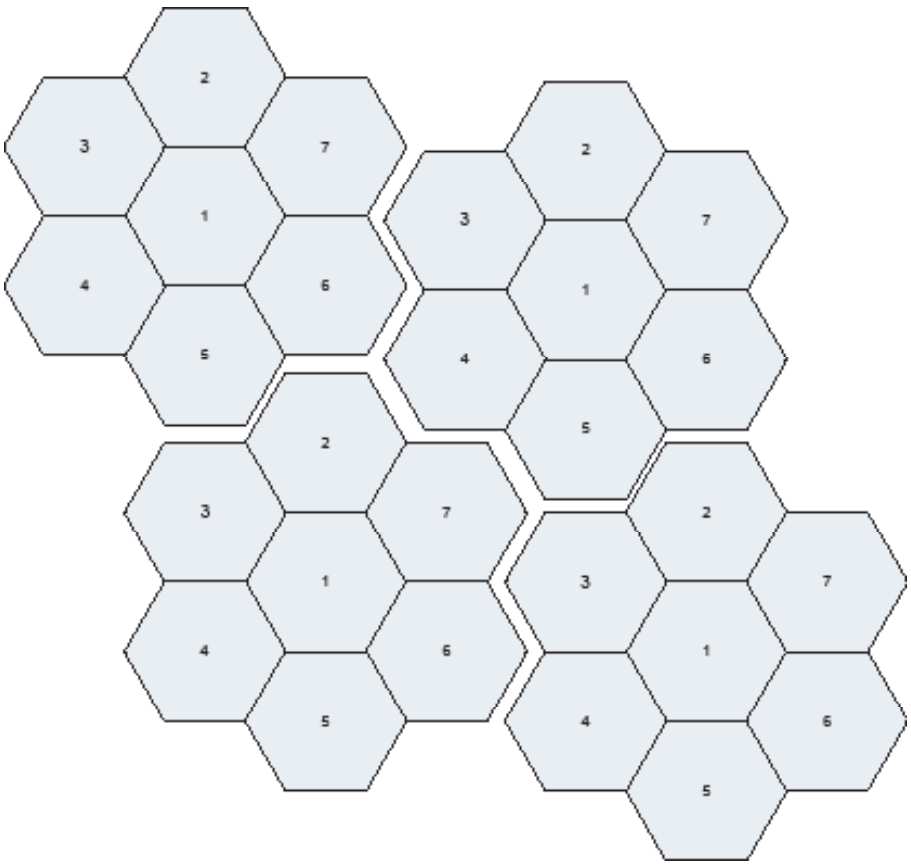
Table 1. Generations of cellular mobile communication networks

Year	Network Standards	Services	Capacity
1980's	1G Analog AMPS TACS NMT	Voice Small data	2.4 kbps – 9.6 kbps
1990's	2G Digital GSM D-AMPS PDC cdmaOne CSD iDEN 2.5 G or 2G+ Digital GPRS HSCSD WiDEN EDGE CMDA2000 1xRTT	Voice SMS Some data Voice Data Email Internet	Up to 48.6 kbps Up to 384 kbps
2000's	3G Digital W-CDMA CDMA2000 1xEV TD-SCDMA	Fast Internet Mobile multimedia Video Phone Mobile TV Remote access	Up to 2Mbps
2010's	4G Digital Wi-Fi UMB UMTS Revision 8 WiMAX WiBro	Mobile Ubiquitous Reality communications (e.g., virtual reality and 3D applications) Multiple services at the same time Personalised communications	Up to 1Gbps

1970s in the Bell Labs as a research project, and commercially launched in America in 1984. It was one of the revolutionary achievements in the mobile communication technologies due to the smaller area coverage and low powered output through the use of the cellular technology. The low powered output produces lower interference, and hence it effectively allows frequency reuse in the form of cell clusters. The cells in a cluster may interfere with their neighbouring cells. To produce minimum interference, frequency reuse must be at least two cells apart. AMPS generally uses either 12 or 7-group cell patterns (Wesel, 1998). An example of a 7-group cell pattern with frequency repetition and separation among them is shown in Figure 2.

This directly yielded a higher capacity system compared with a traditional non-cellular analog mobile system. The division of area coverage into hexagonal cellular regions also provided the

Figure 2. 7-group cell pattern with frequency repetition and separation



mobile users with a greater mobility. AMPS uses frequency division multiple accesses (FDMA) for voice channels and operates in 800-900 MHz. Initially in 1984, the Federal Communications Commission (FCC) allocated 666 channels (333 channels for each carrier) for two carriers—A and B. Lower frequencies were given to the license B, which was owned by wireline companies, while the upper frequencies were allotted to the license A, owned by non-wireline companies. Due to the rapid growth of the mobile cellular users, in 1989 the FCC had increased the channels from 333 to 416 for each carrier, that is, 832 in total (Wikipedia, 2006). Twenty-one of 416 channels are control channels that carry control data, and the remaining 395 channels are used for two way voice communications.

Despite its analog nature, AMPS has countrywide coverage, it is not possible to encrypt and decrypt messages, and therefore, anyone can intercept the call through a handheld radio frequency scanner. Hence, it is not secure at all. Other disadvantages are: the lifetime of the battery is not long enough, poor quality of the transmitted message, and call charge is costly (ePanorama, 2006). For these reasons, AMPS is being replaced with 2G standards such as Digital AMPS (D-APMS), GSM, and so on.

Total Access Communication System (TACS)

Total Access Communication System (TACS) was introduced in Europe in the late 1970s, and

modified after AMPS using FDMA. Therefore, it is an analog mobile communication standard and is known as the European version of AMPS. It is used in the UK, China, and Japan (ePanorama, 2006). Extended TACS called ETACS was introduced in the UK by extending the channel capacity of TACS. Both TACS and ETACS are completely outdated in Europe and replaced by GSM (Wikipedia, 2006).

Nordic Mobile Telephone (NMT)

As with AMPS and TACS, Nordic Mobile Telephone (NMT) is another analog mobile telephone standard and was widely used in Nordic countries. It was introduced in the late 1970s in collaboration with Finland, Sweden, and Norway. There were two versions of NMT—NMT-450 and NMT-900. NMT-450 used 450 MHz frequency, while NMT-900 used 900 MHz. NMT is also completely outdated, and hence it has been replaced by GSM and W-CDMA (Wikipedia, 2006).

Second Generation (2G) Cellular Mobile Networks

The limitations of analog cellular networks have been alluded to in the previous section. To remove these limitations, meeting the ever increasing demand from users, and providing better quality, the countries and individual companies felt the importance for the introduction of digital cellular communication standards called 2G cellular mobile communication standards.

For digital encoding, the 2G standards are able to provide small data transmission in addition to voice communication. Some 2G standards can also provide a few extra advanced services: short messaging service (SMS) and enhanced messaging service (EMS). The digitisation of voice makes it possible to apply filtering or audio compression techniques to reduce the size of the transmitted voice, which leaves some room to multiplex more subscribers into the same radio frequency channel, and produce better quality compared with analog cellular standards by reducing noise. Examples of 2G cellular mobile communication standards include Global System for Mobile Communication (GSM), Digital AMPS (D-AMPS), cdmaOne (IS-95), and Personal Digital Cellular (PDC).

Global System for Mobile Communication (GSM)

Initially, to address many compatibility problems among many digital radio technologies of the European countries, the GSM-Group Special Mobile was formed by the Conference of European Posts and Telegraphs (CEPT) in 1982. After this, the full name of GSM was changed to Global System Mobile Communications, and its responsibility was handed over to the European Telecommunication Standards Institute (ETSI) in 1989 (ePanorama, 2006). The technical specification of GSM was completed in 1990, and it was commercially launched in 1991 from Finland.

From its initial journey, it evolved itself as the most popular standard, and took over 70% of the mobile market with 1.6 billions subscribers in 210 countries all over the world by 2005 (Wikipedia, 2006). The ever increasing popularity of GSM was due to the following main reasons:

- GSM is based on an open system architecture. Therefore, any operator from any country can provide its services using their available hardware.
- It was made compulsory by rule to use GSM in European countries to increase the interoperability.
- GSM first introduced SMS text messaging and pre-paid accounts which are very popular among students and teenagers. Pre-paid accounts also dominated the market of developing countries, since it does not require any accountability or personal verification.

- It can provide a good quality service with moderate level security and can work under a wide range of frequencies.
- The cost is low.
- It can provide international roaming, that is, if a user is overseas, which is not covered by his/her own operator, the user can still receive service by the operator of the visiting location if there is an agreement between those two operators.

The majority of the GSM networks use 900 MHz or 1800 MHz frequency bands. There are some networks in USA and Canada that use 950 MHz or 1900 MHz frequency bands. In addition to these, GSM can also operate on 400 MHz and 450 MHz frequency bands. For multiplexing, it uses a combination of TDMA and FDMA, which allows the operator to allocate up to eight users, one for each time slot, into a single channel. The modulation technique used in GSM is Gaussian Minimum Shift Keying (GMSK), which effectively reduces the inter-channel interferences.

Like Integrated Services Digital Networks (ISDN), GSM can provide the data services—file or data transfer, and send a fax in up to a maximum speed of 9.6 kbps. GSM has been extended in order to increase its speed for providing faster data services. For example, High Speed Circuit Switched Data (HSCSD) is an expanded form of GSM, which can transmit up to 57.6 kbps by using multiple (e.g., eight) time slots for a single user or connection.

Digital AMPS (D-AMPS)

The digital form of the older analog AMPS standard is referred to as Digital AMPS (D-AMPS) or TDMA/IS-136. It is mainly used in the U.S. For transmitting information, it uses 824-849 MHz frequency band, while for receiving information, a frequency band of 869-894 MHz is utilised. The capacity of each radio frequency channel is 30 KHz. Each channel is divided into a number of time slots for squeezing several messages into a channel using the TDMA technique.

cdmaOne (IS-95)

cdmaOne is also known as IS-95. It is one of the 2G mobile communication standards and was originally introduced based on Code-Division Multiple Access (CDMA) multiplexing technology in 1993 by Qualcomm. The two versions of IS-95 are IS-95A and IS-95B (Mobile, 2007). The former operates in a single channel at 14.4Kbps, while the latter can support up to eight channels and 115 kbps.

Personal Digital Cellular (PDC)

Personal Digital Cellular (PDC) is a 2G Japanese digital cellular standard. After its introduction, it was widely used in Japan. This standard enforced Japanese to look into another alternative standard, as their old standard was incompatible with all other existing standards. For this reason, cdmaOne was gaining popularity in Japan in the late 1990s (Andersson, 2001).

Evolutions of GSM

As GSM is a circuit-switched mobile telephone network, it provides the limited amount of data services. In circuit-switched networks, dedicated connection is established for the entire life of a call and users usually need to pay per minute, whether they do or do not use the allocated connection. Another problem is users are charged as per usage time, and if it requires transmitting data through GSM, it needs to set up a dial-up connection. These issues acted as the driving force for the evolution of GSM, and consequently, it evolved itself into a packet switched network, namely General Packet Radio Services (GPRS) for providing the facilities of a data network Internet. An extra network, namely GPRS core network is built on the bedrock of the GSM network, collectively called GPRS

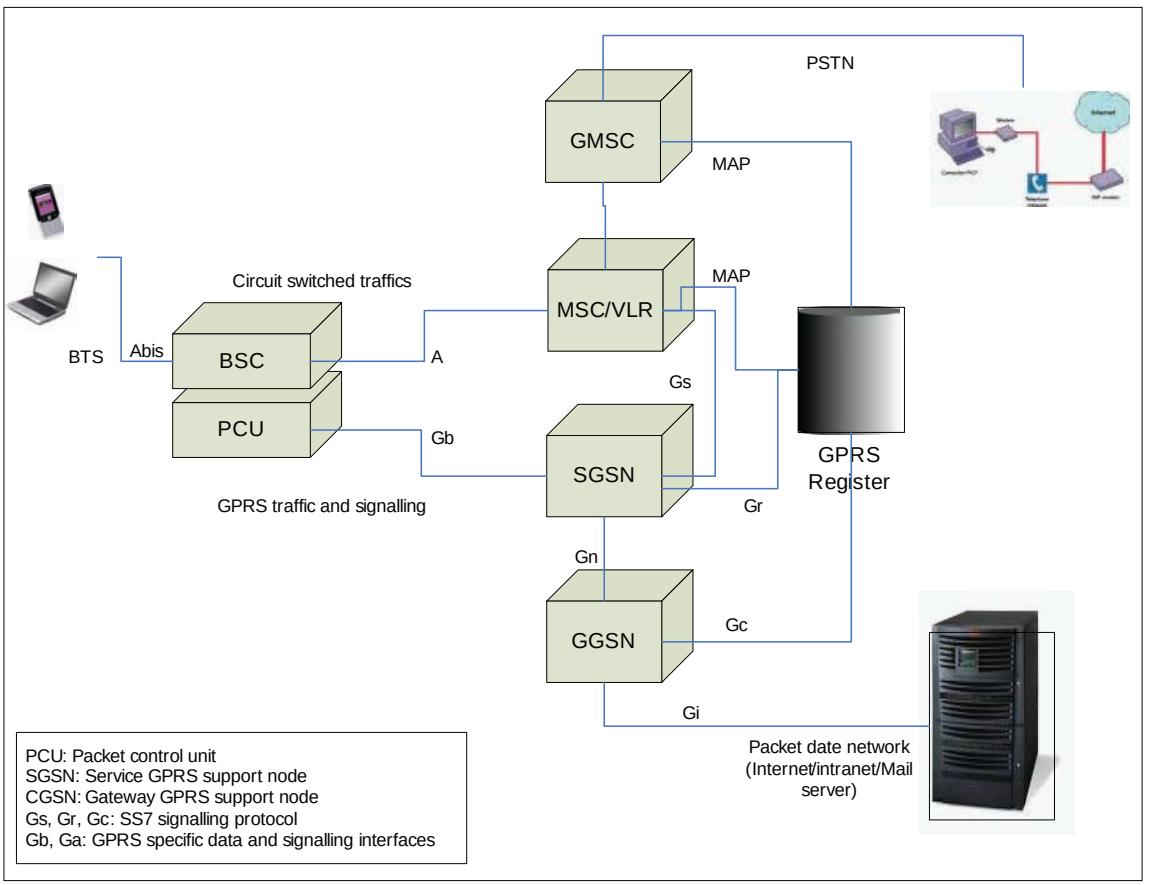
network. It allows GSM users to receive both vice and extra data services—mainly Internet browsing, e-mail, file and data transfer, and so forth. The architecture of the GPRS network is shown in Figure 3.

GPRS is regarded as 2.5 generation mobile network. GPRS is always online, that is, it provides the immediate data services whenever users require, just like a leased line or broadband Internet connection in which charges are based on data being transferred, or a flat rate provided by a particular operator. In contrast as mentioned previously, GSM usually charges based on the duration of a call, regardless of whether data is being transferred or not. The way of accessing both voice and data depends on the types of Capabilities—Class A, Class B, and Class C.

Class A provides the simultaneous access of both voice and packet data services. Class B provides voice and packet data services one at a time with a higher priority given to voice. If a voice call arrives, packet data services will be suspended, and resume back automatically at the end of the voice. Class B is the most common and is provided by most of the operators. Class C requires manual switching between voice and packet data by an operator (Wikipedia, 2006; Andersson, 2001).

There are eight TDMA time slots. The maximum capacity of each time slot is 20kbps. Therefore, theoretically GRPS can provide up to 160 kbps, however, this is limited by the multi slot classes (number of time slots used for downlinks, uplinks, and active slots), and the type of

Figure 3. The architecture of the GPRS network



encryption techniques used. The four encryption techniques used in GPRS are CS-1, CS-2, CS-3, and CS-4. CS-1 is the robust encryption technique, and hence it can accommodate 8kbps and cover 98% of the normal coverage, while CS-4 is the least robust encryption technique, which provides the data rate 20kbps and covers only 25% of the normal coverage area (Wikipedia, 2006).

Third Generation (3G) Cellular Mobile Networks

3G is a modern day mobile platform that has replaced the existing 2G standards. Some of the features of 3G articulated by IMT2000 include hierarchical cell structure, global roaming, and an expanding radio spectrum (Akyildiz, McNair, Ho, Uzunalioglu, & Wang, 1999). The claimed benefits of upgrading from the legacy networks mainly used for voice and SMS to 3G are endless. TV direct to your mobile, video calling, fast mobile Web browsing, and remote access are just the icing on the cake with the enormous potential of 3G. The most influential application for 3G was predicted to be video calling. With the deployment of 3G comes increased bandwidth, which opens a whole new world of possibilities.

The reasons for the delay of the rollout of the 3G network in some countries were due to:

- The costs involved in building new networks;
- Costs of additional spectrum licensing;
- Frequency distribution variation between 3G and 2G networks; and
- Costs of upgrading equipment.

However, Japan has been the leader for 3G on a commercial scale, with an expected extinction of the 2G network by 2006 (Hui & Yeung, 2003).

One of the 3G standards is Wideband Code Division Multiple Access (WCDMA) technology, a higher speed transmission protocol used in an advanced 3G system, designed as a replacement for the aging 2G GSM networks deployed worldwide. WCDMA provides a different balance of cost in relation to capacity and performance. WCDMA promises to achieve reduced costs and provide more value for day-to-day applications (Wikipedia, 2006).

3G broadband mobile communications makes access to sophisticated workplace technology inside the 3G handset even faster, making working life more flexible and developing still further the "virtual office" complete with e-mails, video conferencing, and high speed access to services without the daily commute. WCDMA works on a higher frequency in comparison to GSM and therefore travel a shorter distance.

Obviously, the real applications for 3G are the real-time ones. They include video telephony (video conferencing), video streaming, remote wireless surveillance, multimedia real-time gaming, video on demand, and more. These applications will drive usage and increase service-provider revenue. Consequently, they also will raise equipment sales (Hackett, 2001; UMTS World, 2003).

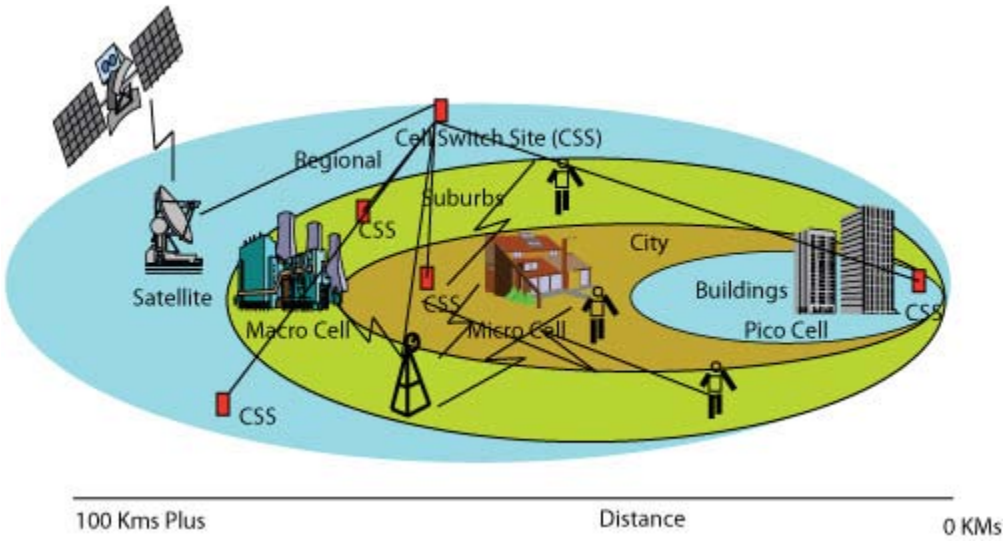
Hierarchical Cell Structure (HCS)

This portrays the different environments and cell structures across a given area.

The capacity is conversely proportional to coverage. The hierarchical cell structure shown in Figure 4 will cover all areas of the mobile user, thereby giving the user wider coverage and mobility starting from the high capacity pico-cell to the large global cell. Since the satellite takes part into the congestion control and it is a global extension to micro and macro cells, the capacity of 3G networks will increase, and hence it is capable of providing the services with more users (Akyildiz et al., 1999).

Figure 4 highlights the different operating environments for the mobile user. The mobile user will access wireless networks using the mobile terminal. This terminal uses radio channels to

Figure 4. The hierarchical cell structure



communicate with the base stations. This gives the user access to the terrestrial networks. As the distance increases the bandwidth decreases, with the bandwidth at its maximum in the pico-cell. However, although the quality of service (QoS) drops with distance, the coverage is transformed from base stations to satellite using the fixed Earth stations in areas of remote access. Finally, there are a number of cell site switch (CSS) that govern a number of base stations. These CSSs manage the radio recourses and provide mobility management control, location updates, and manage global roaming.

Global Roaming

The third generation wireless networks begin to implement terminal and personal mobility as well as service provider portability. Terminal mobility is the ability of a network to forward a call to a mobile terminal irrespective of its attachment point to the network. This means if the user is in an area of poor coverage the mobile will automatically shift to a service provider with strong coverage in the area giving the user good QoS. Personal mobility provides the users with an access to their personal services regardless of their attachment points to the network or mobile terminals (Akyildiz et al., 1999).

This level of global mobility freedom will be dependent on the coordination of a wide range of service providers to build a compatible backbone network and have strong agreements and cost structure. The first step is the development of global roaming agreements between different countries.

Radio Spectrum

Previously frequencies were allocated to specific sectors such as paging, cellular, mobile data, and private mobile radio. In 3G the radio spectrum is designed to standardize a pool of frequencies which could be managed to meet the global market needs and the technological developments. IMT2000 is designed to provide a spectrum of frequencies across different nations to meet with the demands of the mobile world, and hence it provides connections to heterogeneous backbone networks both wired and wireless.

Radio waves used to deliver 3G services are transmitted at a higher frequency than for 2G and travel a shorter distance. This may lead to coverage area or cell size for a 3G base station being smaller

than 2G site. Also, with the increase in demand from users in a particular cell, the size of that cell shrinks; the only way to ensure QoS is to overlap between cells. Therefore, the QoS in a high usage environment will decrease due to factors such as conjunction, interference, and static.

The location of cell sites is critical with 3G networks to avoid interference between adjacent cells, which in turn is one of the major issues to be addressed. Researchers are always looking to develop ways to better share the frequency and increase the bandwidth (Ariyoshi, Shima, Han, Karlsson, & Urabe, 2002). One of the solutions implemented is time division duplex (TDD). This application is designed to separate outward and return signals on the frequencies being used. TDD has a strong advantage in the case where the asymmetry of uplink and downlink data speed is variable (Wikipedia, 2006).

Another technique that is used is frequency division duplex (FDD), in which the uplink and downlink sub-bands are said to be separated by the frequency offset. FDD is more efficient in the case of symmetric traffic. FDD also makes radio planning easier and more efficient, as the base stations transmit and receive on different sub-bands. FDD is currently being used by the 3G network and works consistently, giving the user two separate frequencies to avoid interference (Wikipedia, 2006).

Key Characteristics and Application

This section will highlight some of the key applications offered as a result of the rollout of 3G. Each application will be described in relation to practicality in the industry sectors, and critical feedback on the deployment and operations will be discussed. In areas where problems have been identified, a brief overview will cover the cause of the problem with recommended solutions (UMTS World, 2003).

Fixed-Mobile Convergence (FMC)

Fixed-mobile convergence (FMC) is based on the use of dual-mode handsets. However, it is a broad area. For the purposes of this section, FMC means the converging functionality between desk phones and mobiles—set the mobile as a dual identity where the mobile can be addressed as a desk phone and mobile at the same time.

FMC essentially is a system designed to ensure corporate users can, for example, expect the same functionality from their PBX as their mobile and vice versa—same address book, call redirection, call transfer, message bank, and so on.

Some key characteristics of FMC include:

- Convergence of desk phone with mobile;
- Mobile convergence integrated with VoIP over the PABX;
- Functional transparency (address book, message bank, caller redirection, etc.);
- Anytime, any place access to employees; and
- Cost savings by organisation and clients.

The implementation of FMC has raised a few concerns in regards to employee security, PABX security, routing costs, and implementation of hardware that will enable a mobile to automatically convert to a part of the PABX and vice versa. The implementation of FMC is dependant on a few basic system characteristics such as:

1. Can a mobile have a dual identity?
2. What area of coverage will mobiles act as a part of the PABX and the security measure required?
3. What are the costs associated with implementation of hardware and software that will work over the two different systems?
4. Is it possible for the mobile to have the intelligence to recognize a call between the PABX and the mobile network?

The main advantage of FMC is the increased reach capacity of staff within the organisation. The other benefit is the cost saving structure for the firm routing calls via the PABX system.

Sales Force Automation

The sales force is the backbone of most organisations. 3G services are designed to introduce a new level of flexibility and convenience in the day to day life of the sales force. Figure 5 is an example of areas where 3G in conjunction with sales force automation (SFA) software can add value to the operations within organisation.

Some applications introduced to the sales force are:

1. Direct link from the mobile device (lap top or PDA to the company server);
2. Access to e-mail on the road;
3. Video calls; and
4. Wireless broadband service anywhere and anytime.

As 3G speeds increase in the future, and HS-DPA rollouts take place, the true potential of such mobile applications is likely to grow. The issue of bandwidth will be history and the connection problem will be rectified with permanently connected devices (Gartner, 2005).

SFA software will provide an interface that will link the user to different departments within the firm accessing real-time updates on order, inventory management, virtual conferences, and client data.

At the moment return on investment may be hard to forecast in terms of dollar value but as the systems develop the question will not be "how much does it cost to implement?" but rather "what are we missing by not have the application?" Some of the benefits driving the deployments are:

- Speed of business: agents can have access to client data immediately;
- Make changes in real time;
- Improving accuracy for logistic and inventory management;

Figure 5. Schematic diagram for mobile sales force automation

- Real-time solutions and access to real-time information; and
- Quick response time in coordinating within the organisation.

The current problem is the lack of custom SFA software in the marketplace. In cases where custom built SFA application are required, the cost seems to outweigh the benefits. There is also the case of overloading to many applications onto one small devices for it to be useful, which may turn it into a threat rather than a tool. The trick is getting companies to figure out what the key activities are and where the sales force will benefit from having mobile device access and focus on those.applications.

VoIP Mobile

VOIP integrated mobile services are still on the agenda. The use of the Internet as the sole platform to make calls is still not developed. The biggest benefit of mobile VoIP is having the ability to call over the Internet—in other words, creating huge cost savings. Unfortunately, this assumption is not true; the cost for organisations to set up mobile VoIP still seems to be expensive as it is in its infancy stages. That is not to say that the cost will gradually subside with developments in the field and time.

A number of companies are on the bandwagon trying to produce new developments to ensure quality of service. The two key factors in implementing successful VoiP is: (1) to increase the bandwidth; and (2) to ensure seamless flow of information from one point to another.

One in every five companies are looking into FMC—for most, it is cost savings rather than mobile VoIP, FMC is predicted to be the next big boom. It is believed that mobile VoIP will be an application running on 4G networks rather than the current 3G platforms.

Mobile TV

Mobile TV poses no direct benefit for the firms—companies are concerned it will be a distraction to the employees rather than a benefit. Mobile TV is targeted towards the mass audience rather than companies. For example, a certain target group would use this option to watch a football match or other similar programs.

The problem, however, is the end result—a fan or an enthusiast of a particular sport would prefer to watch the event on a big screen and with the ease of access to a number of venues. Mobile TV does not seem feasible. Businesses could incorporate mobile TV as a sales channel to run their advertising. For example, the GPRS on the phone might pick up a movie theater in the vicinity and automatically play the trailer of a movie.

Corporations will not spend money on unnecessary functionality such as mobile TV. To the general public, mobile TV is not a practical application due to a few reasons: (1) the end result (looking at a show on such a small screen); (2) the cost of usage; and (3) ease of access to substitute options to view programs.

Video Calling

According to the Shosteck Group, the size of the market for video messaging and calling will reach an estimated US$10 to US$28 billion by 2010, while in 2005, the Yankee Group estimated that already in 2007, video services will generate revenue of more than US$3.5 billion. Video calling was set to be the key element that would differentiate 3G from 2G. The modern user can see the direct benefits of video images and real-time interaction on their phones. There is now no doubt services based on video are emerging as a major source of operator revenue.

Nokia's own estimate is that the market for mobile entertainment and media services, including music, ring tones, mobile TV, and browsing, will have a value of around 67 billion euros in 2010.

This market will be flooded with a variety of video entertainment services (Le Maistre, 2002).

Until today, most users believe that 3G refers to video. This is because most service providers use the video calling as a flagship service in 3G launch, the person-to-person video call has already emerged as a key differentiator for 3G technology. Nokia studies show that as far as building 3G awareness among users go, the strategy has worked well in many markets. For example, according to research by Nokia in Hong Kong, Italy, Japan, and Korea in 2005, the vast majority of users in live networks named video calling as the key reason for subscribing to 3G (Orr, 2004).

However, the basic person-to-person video call is not available for EDGE networks, which may limit the service's appeal to operators pursuing joint 3G/EDGE deployment strategies. Lack of EDGE support will mean a lower user base for the service, which limits the value of the service to users as they will be able to contact fewer people.

Some users are also reluctant to subscribe to the service because of privacy concerns—they often do not like the idea of their face being seen on somebody else's terminal first thing in the morning (Lemay, 2006).

Video calling is real time and therefore dependant on the quality of service with demands on the bandwidth and consistent packet interchange without interference, congestion, or static. In reality, the technology of today still does not seem to have the quality of service for video calling because it is directly dependent on real-time transfer of information (UMTS World, 2003).

The Future of 3G

The ways of doing business is changing the usage of IT and communication departments of every business amalgamating into one unit unlike never before, with the IT sector being the driving force for the benchmarks set by communication demand.

The mobile phone is ever changing, providing the user with one key characteristic in today's timeless world—convenience. With the mobile phone integrated into our day-to-day life in more ways than one, the introduction of IP into the communication world will transform its existence into a compact and user-friendly "computer". This will bring in the introduction of 4G.

Fourth Generation (4G) Cellular Mobile Networks

Third generation (3G) mobile networks have given emphasis on the development of a new network standard and hardware such as IMT2000, and the strategy to dynamically allocate frequency spectrum. The major hindrances for the introduction of 3G are the development of new technologies, and how to take away all frequencies from all countries and put them in a common pool. These problems are the main causes for the delay in the development of 3G networks. In spite of these, 3G can provide 2Mbps into a limited coverage area, that is, up to the macro (urban) cells. To solve these problems and to provide high-speed transmission and wider coverage, fourth generation mobile networks have been targeted to develop as IP-core heterogeneous networks. It is expected to be commercially launched by around 2010. There are a number of characteristics of 4G networks from users', operators', and service providers' point of views. From a user's point of view, 4G networks should have the following characteristics (Hui, 2003):

- The services of any networks ranging from body area to global communication networks including ad-hoc, sensors, and intelligent home appliances, should be available at anytime-anywhere irrespective of users' geographical locations and terminal devices. For example, users located anywhere in the world want an instantaneous access to their required service(s) provided by a number of

networks with their existing terminals. This is possible since 4G networks are IP-core.

- High transmission of data including 3D enhanced real-time audio and video information with low transmission cost. The demands of users for multimedia data are rapidly increasing every day. However, concomitantly, users want affordable and lower usage cost. The multimedia information, especially audio and video, requires a high bandwidth, which inherently incurs a high transmission cost since the Internet provides high transmission services with lower cost. To address this catch-22, 4G networks have taken IP as a core or backbone.
- Personalised and integrated services: Personalised services mean all types of users from different geographical locations and professions are able to receive the services they want in their customised ways using their available terminal devices. Integrated services mean users can simultaneously access multiple services from a number of service providers or networks using their same terminal devices. An example of integrated services is when a particular user with the same terminal device can concurrently browse the Internet using GPRS, make a phone call to their friend using GSM and see cricket live on television, or watch a program using W-CDMA networks (Hui & Yeung, 2003).

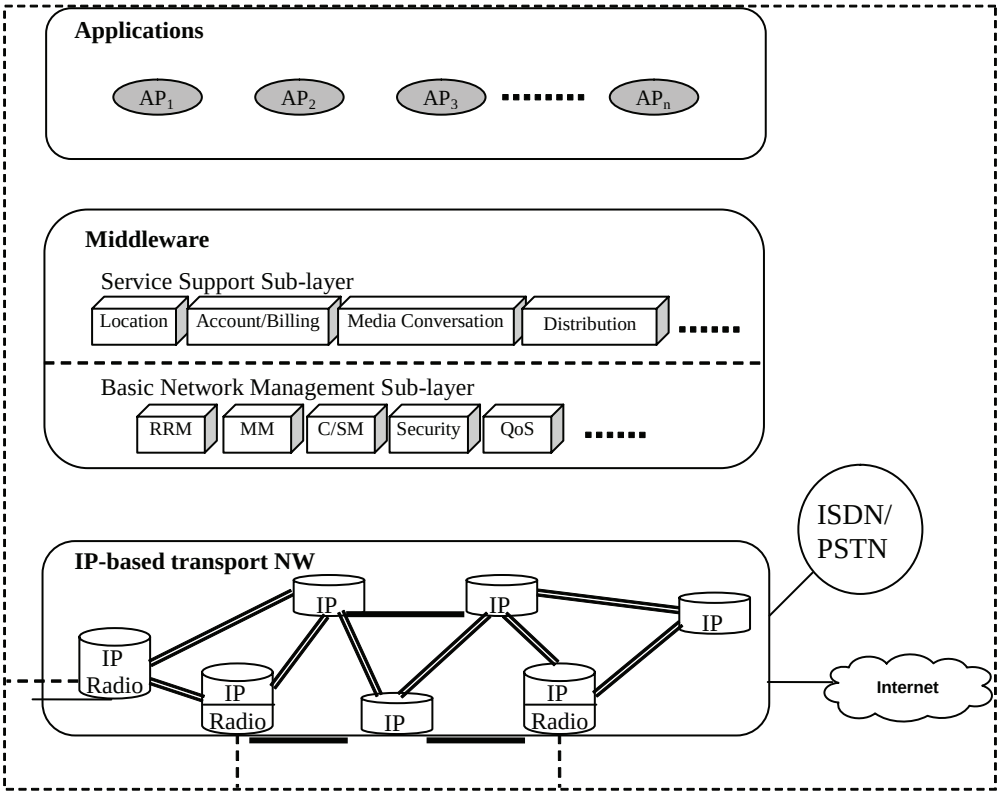
A wide variety of 4G network architectures has been developed, which can be classified into the following two approaches:

1. Interworking: For the interworking among different networks such as ad-hoc, wireless LAN, cellular, digital video broadcast-terrestrial (DVB-T), digital audio broadcast (DAB), satellite, and so on, new standard radio interfaces and technologies for 4G will be developed so they can provide seamless access and services to users. An example of 4G mobile networks architecture based on the interworking approach is presented in Muñoz and Rubio (2004), which comprises personal level (e.g., ad-hoc, wireless PAN), local level (e.g., Wireless LANs), national level (e.g., UMTS, GSM, and GPRS), regional level (e.g., DAB and DVB-T), and global coverage (e.g., satellite) networks.
2. Integration: During the development of 3G technologies, there are number of technologies which are being developed separately, such as Bluetooth, wireless local area networks (WLAN—IEEE 802.11), high performance radio LAN (HIPERLAN—IEEE 802.11a), and IMT2000. Each of these technologies has its own advantages and disadvantages. There is no such single technology which can provide the facilities of all these technologies. Therefore, researchers are giving emphasis on the development of 4G architecture by seamlessly integrating these existing technologies. A representative example of these architectures is presented in Figure 6 (Ruiz, 2002).

All existing wireless networks starting from wireless personal area networks (PANs) to global satellite networks are to be connected to an IP-based backbone in a hierarchical order. An example of a hierarchy of wireless networks connected to an IP-based backbone is shown in Figure 7.

This hierarchical structure confirms that when a user is connected to a personal network layer (e.g., in an office, airport, shopping mall, hotel, visitor centre, or train station), the user will receive a high bit rate transmission. In comparison, when a user moves in the upper layers (e.g., highway, beach, and remote area), the user will automatically be connected to the upper layer networks (e.g., WLAN, 2G and 3G cellular, DAB and DVB-T, and satellite). For mobility management, this structure supports both horizontal and vertical handoffs. When a mobile terminal moves through the same network layer, a horizontal handoff

Figure 6. General architecture of the IP-based 4G network platform based on integration approach



RRM= Radio resource management *MM: Mobility management*

C/SM: Connection/session management

takes place. If a mobile terminal moves across the network layers, a vertical handoff takes place. To meet the demands from users, operators, and service provides, and to seamlessly integrate the available network technologies, 4G networks possess a number of research challenges considering the aspects of mobile terminals, network systems, and mobile services that are described as in the following sections (Hui & Yeung, 2003; Ray, 2006).

Key Challenges of Mobile Terminals

Multimode Mobile Terminals

Single mobile terminals should be capable of accessing services from different mobile network technologies by automatically reconfiguring itself with them. The design of such a mobile terminal poses a number of problems related to high cost and power consumption, limitation in terminal size, and interpretational capability with downgraded technologies. An approach based on software radio has been proposed to adapt a mobile terminal with the interfaces of various network technologies (Buracchini, 2000).

Automatic Network System Discovery

A mobile terminal should be able to automatically detect its surrounding available wireless networks by receiving the signals broadcasted by them. For this, the multimodal terminal needs to scan the signal quickly as well as accurately from a number

of diverse networks comprising different access protocols. This makes the job difficult and challenging. To address this issue, a software radio is suggested to use in scanning the signals sent from heterogeneous networks.

Automatic Selection of a Network System

Multimode mobile terminal is required to automatically select a suitable wireless network for each service. This may need an optimisation of each user requirement for each session based on available network resources, network service capability, and both application and network quality of service (QoS) parameters. While this can be a time-varying multivariable optimisation technique, it may involve complex intelligent processing of different network characteristics as alluded to earlier, including user profile and preference. Despite a number of solutions which have been introduced considering some of the previously-mentioned criteria, a number of issues are yet to be solved to select a suitable network (Hui & Yeung, 2003).

Key Challenges of a Network System

Terminal Mobility

Terminal mobility means the ability of a communication network to locate a mobile device anytime anywhere in the world, and hence route a call to that particular device irrespective of its network point of attachment. This system facility allows a mobile user to have a global roaming, that is, to roam the different geographical locations all over the world. For this, network systems need to have an efficient mobility management system, which includes both location and handoff managements. Location management mainly locates and updates the location of a mobile terminal, while handoff allows the continuation of a call when a call is in progress, regardless of the movement of a user or terminal across wireless networks. IP-based mobility management has been incorporated in mobile IPv6 (MIPv6) (Hui & Yeung, 2003).

In spite of its enhancement to reduce high handoff latency and packet loss, handoff management remains a fairly complex process due to an unacceptable degradation of QoS for real-time multimedia transmission, and not being able to measure the accurate handoff time. This is because, as shown in Figure 7, 4G requires both horizontal and vertical handoffs across wireless networks. To address this issue, researchers are investigating ways to develop an efficient handoff management scheme.

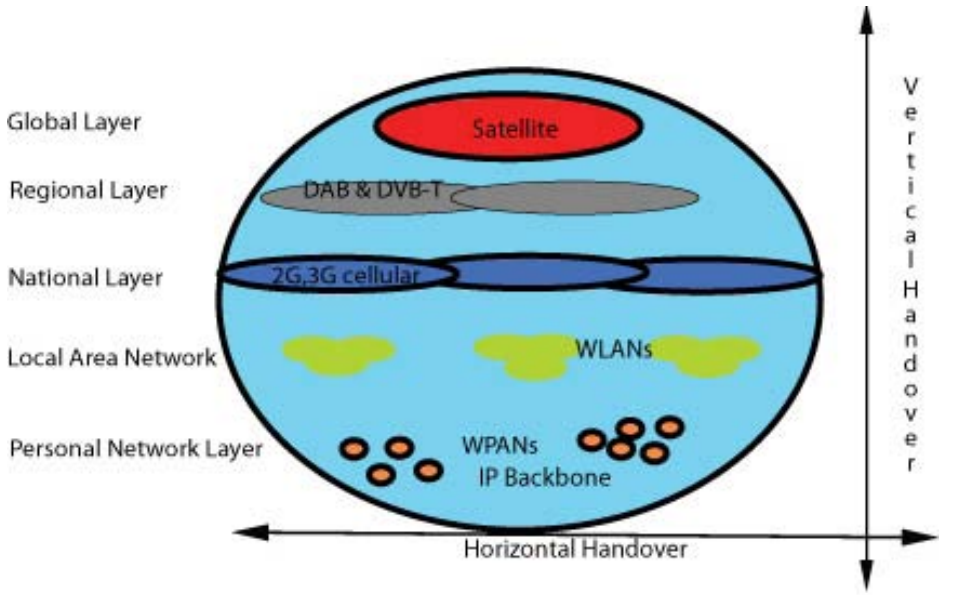
Adaptive and Light Weight Security System

Much of the existing mobile communication networks are mainly circuit switch based, that is, non-IP core. For this reason, the security standards which have been developed so far are mainly for non-IP based networks, and therefore are not directly applicable to IP-based mobile communication (4G) networks. In addition, to achieve the expected performance of QoS parameters, different standards have adopted different security schemes. For example, GSM has optimised its security for mainly voice delivery (Hui & Yeung, 2003). A particular security scheme is not suitable for 4G networks as it comprises a number of heterogeneous networks. Therefore, a light weight security system is needed to be developed, which can dynamically reconfigure itself considering the network and service types, operating environment, and user preference, and so forth.

Fault Tolerance and Network Survivability

Much effort has not been given to increase the fault tolerance and network survivability of wireless networks compared with wired networks. While the wireless networks are more vulnerable than wired networks due to its tree type hierarchical

Figure 7. Hierarchy of wireless networks connected to IP-based backbone



structure, if damage occurs in a particular level, it may affect the whole level including all of its underlying levels. This becomes more serious for 4G networks because it consists of heterogeneous multiple tree types networks (Hui & Yeung, 2003).

Key Challenges of Mobile Services

Integrated and Intelligent Billing System

As mentioned in the beginning of this section, users' demand for 4G mobile communication networks to access any service from any network using any mobile device anywhere in the world. This enforces the system to keep record of who uses what service from which service provider, and its related rate information. Each service provided by a particular provider has its own charging scheme with negotiated QoS parameters. For example, in Australia, charges for 3G mobile cricket are different from that of browsing the Internet through a mobile device. Even for the same service, the billing scheme varies from provider to provider. For example for a particular service, namely the Internet, some service providers offer a flat rate, while others charge as per usage, such as time and data. In addition to these, some providers have introduced their charging scheme based on usage time zone, such as peak, non-peak, and free time. These factors make the billing system challenging and complicated, which is difficult enough for users to record and pay all bills they received from each service provider separately. This enforces users to demand a unified single billing system. However, to produce a single bill using all usage history requires an intelligent broker service (Hui & Yeung, 2003). In order to produce such a unified billing system, researchers are now delving into all possibilities.

Personal Mobility

Personal mobility is one aspect of mobility management and global roaming. Personal mobility refers to the capability of a user to access any service from any network using any mobile terminal regardless of his network attachment point. Thus, this important characteristic of mobility management enables a user to receive a

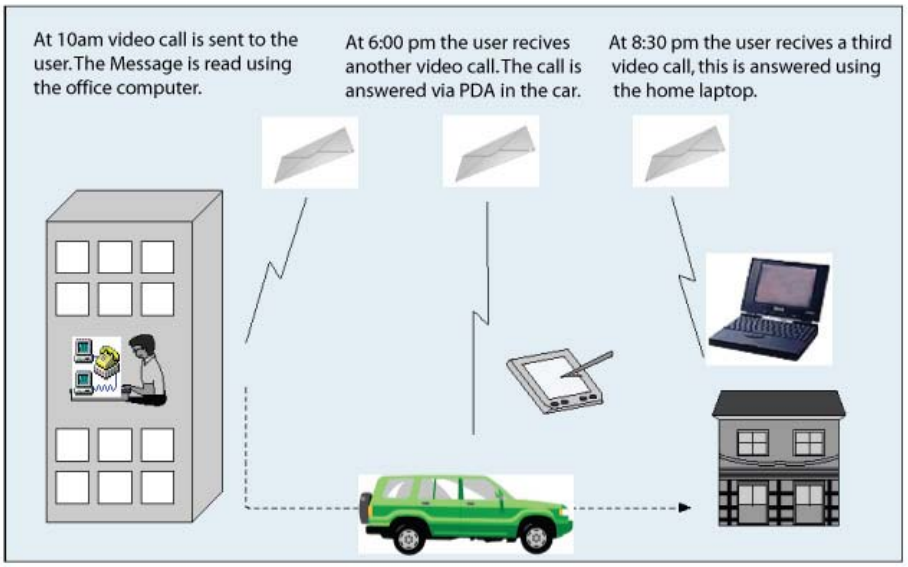
personalised service through his profile, that is, his preferred location, choice, and mobile devices. An example of a personalised service for a particular user, namely Mary for her video messages, is shown in Figure 8 (Hui & Yeung, 2003).

For this, a user is accessing her personalised video call at different times, and in different operating environments. Researchers have introduced a number of schemes for personal mobility management. Most of them are mainly based on mobile agent.

SUMMARY

The birth of mobile communication is mainly to fulfil people's expectation to communicate with anyone, anytime, anywhere. The transmission of multimedia through mobile communication networks and the competition to present equivalent services of wired communication networks is widely in demand. The elements of multimedia are text, image, audio, and video. The audio includes voice and music. The first generation mobile communication networks were analog, and mainly for voice services. There was no security scheme. The communication speed was also very low and covered a limited distance, and a limited number of users. To address these issues, there was a birth of 2G mobile communication standards which are in digital transmission. In addition, to afford higher voice transmission rates, 2G standards also provide SMS and data services. SMS services have been very popular with young people all over the world. Since 2G standards are unable to support e-mail and Internet services, some 2G standards have been enhanced to 2.5G to increase the transmission speed, as well as to afford those services. The maximum transmission rate supported by 2.5G is 384 kbps, which is not sufficient for application services that involve audio and video transmission such as mobile TV and video conferencing. For this, 3G generation mobile communication has recently appeared in the market to provide broadband communication, that is, up to 2Mbps transmission. This transmission rate is not sufficient for real-time multimedia information communication.

Figure 8. Personal communication using a personalised video message



Furthermore, the future of 3G is not clear enough because of the need to develop new standards and hardware, as well as the difficulties to develop a unified frequency pool. However, there are other technologies that are available such as Bluetooth, Wireless LAN, HyperLAN, GPRS, and UMT2000. Each system has their own merits that are worthy to consider for 4G. These factors, including the demand for personalised communication services from any service provider all over the world, 4G mobile communications standards are projected to develop and include existing cutting-edge technology, and future technologies. Since the different standards have different types of services, security and billing systems, it poses a huge key research challenge for mobile terminals, network systems, and services that are also briefly described in this chapter.

Chapter 1.11
Discovering Multimedia Services and Contents in Mobile Environments

Zhou Wang
Fraunhofer Integrated Publication and Information Systems Institute (IPSI), Germany

Hend Koubaa
Norwegian University of Science and Technology (NTNU), Norway

ABSTRACT

Accessing multimedia services from portable devices in nomadic environments is of increasing interest for mobile users. Service discovery mechanisms help mobile users freely and efficiently locating multimedia services they want. The chapter first provides an introduction to the topic service discovery and content location in mobile environments, including background and problems to be solved. Then, the chapter presents typical architectures and technologies of service discovery in infrastructure-based mobile environments, covering both emerging industry standards and advances in the research world. Their advantages and limitations, as well as open issues are discussed, too. Finally, the approaches for content location in mobile ad hoc networks are described in detail. The strengths and limitations of these approaches with regard to mobile multimedia services are analyzed.

INTRODUCTION

Recently, the advances in mobile networks and increased use of portable devices deeply influenced the development of multimedia services. Mobile multimedia services enable users to access multimedia services and contents from portable devices, such as laptops, PDAs, and even mobile phones, at anytime from anywhere. Various new applications, that would use multimedia services on portable devices from both the fixed network backbone and peer mobile devices in its proximity, are being developed, ranging from entertainment and information services to business applications for M-Commerce, fleet management, and disaster management.

However, to make mobile multimedia services become an everyday reality, some kinds of service infrastructures have to be provided or enhanced, in order to let multimedia services and contents on the network be discovered and utilized, and simultaneously allow mobile users to search and request services according to their own needs, independently of the physical places they are visiting and the underlying host platforms they are using. Particularly, with the explosive growth of multimedia services available in the Internet, automatic service discovery is gaining more and more significance for mobile users. In this chapter we focus on the issue of discovering and locating multimedia services and contents in mobile environments. After outlining necessary background knowledge, we will take an insight into mobile multimedia service discovery. Major service discovery architectures and approaches in infrastructure-based networks and in mobile ad hoc networks will be investigated. We present also a detailed analysis of their strengths and limitations with regard to mobile multimedia services.

DISCOVERING MOBILE MULTIMEDIA SERVICES AND CONTENTS IN INFRASTRUCTURE-BASED ENVIRONMENTS

Overview

In order to use various multimedia services on the network, the first necessary step is to find the exact address of service providers that implement the service. In most cases, end users might only know what kind of service (service type) and some service characteristics (e.g., data format, cost) they want, but without having the server address. Currently, browsing is one often-used method to locate relevant information. As the number and diversities of services on the network grow, mobile users may be overwhelmed by the sheer volume of available information, particularly in an unacquainted environment. On the other side, user mobility presents new challenges for service access. Mobility means that users probably change their geographic locations frequently. Consequently, services available to users will appear or disappear dynamically while users move here and there. Moreover, mobile users are often interested in the services, (e.g., malls, restaurants) in the close proximity of his or her current place. Therefore, unlike classical distributed environments where location is often kept transparent, applications often need to dynamically obtain information that is relevant to their current location. The service search procedure should be customized according to user's context, (e.g., in terms of when (i.e., time) and where (i.e., location) a user is visiting).

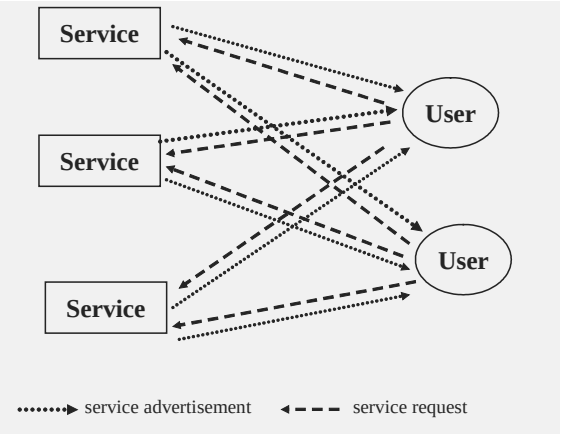
Since most current multimedia services are designed for stationary environments, they do not address these issues. Recently, a number of service discovery solutions are developed. These solutions range from hardware-based technologies such as Bluetooth SDP, to single protocols, (e.g., SLP and SDS) to frameworks such as UPnP and Jini. From architectural point of view, we observed three models are used to discover services in different network environments (Wang, 2003): the broadcast model, the centralized service directory model, and the distributed service directories model. Next, we will investigate these paradigms in detail.

Broadcast Model

The simplest architecture for service discovery is using broadcast to locate services and contents. The conceptual scheme of the broadcast model is depicted in Figure 1. In this model, clients and servers talk directly with each other through broadcast or multicast.

According to who initiates the announcement and who listens, two strategies are differentiated. The first strategy is the *pull strategy* where a

Figure 1. Broadcast model



client announces his requests, while all servers keep listening to requests. The servers that match the search criteria will send responses (using either unicast or multicast) to the client. The other strategy is the *push strategy*. The servers advertise themselves periodically. Clients who are interested in certain types of services listen to the service advertisements, and extract the appropriate information from service advertisements. Of course, hybrid strategies are applied by some approaches.

The **simple service discovery protocol** (**SSDP**) is one typical approach based on the broadcast model (Goland, Cai, Leach, Gu, & Albright, 1999). The SSDP builds upon HTTP and UDP-multicasting protocols, and employs a hybrid structure combining client announcement and service announcement. When a device is newly added to the network, it multicasts an "ssdp:alive" message to advertise its presence. Similarly, when a client wants to discover services, it multicasts a discovery message and awaits responses.

The broadcast model works well in small simple networks, such as home and small office. The primary advantage of such systems is that they need "zero" or little configuration and administration. Besides, they accommodate well to frequent service join/leave actions in a dynamic environment. However, they usually generate heavy network traffic due to broadcast, and thus have only minimal scalability.

In order to improve scalability and performance, an additional entity, service directory, is introduced. Two different models use the service directory: the centralized service discovery model and the distributed service directories model. Both models will be presented in the following sections.

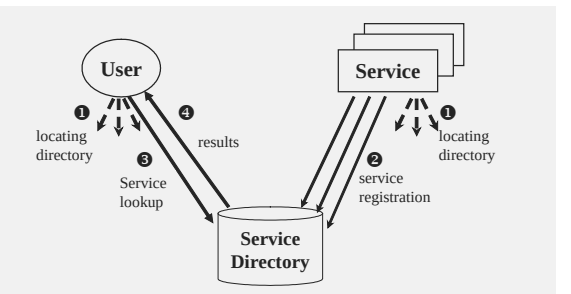
Centralized Service Directory Model

The conceptual scheme of the centralized directory model is shown in Figure 2. The service directory becomes the key component in the search discovery architecture, because it stores information about all available services.

The service discovery procedure consists usually of the following steps:

1. **Locating directory:** Either clients or servers should determine the address of the service directory before they utilize or advertise services. The directory could be located by manual configuration, by querying a well-known server, or through broadcast/multicast requests/replies.
2. **Service registration:** Before a service can be found by clients, it must be registered in the appropriate directory. A service provider

Figure 2. Centralized directory model



explicitly initiates a registration request to the directory, and the directory stores the service data in its database. The service description data include service type, service attributes, server address, etc.

3. **Service lookup:** As a client searches for a particular service, he describes his requirements, e.g. service type and desired characteristics, in a query request, and sends it to the directory.
4. **Searching:** The directory searches services in its database according to the criteria provided by the client. When services are found, the server addresses and other information of qualified services are sent back to the client.

The centralized directory model has been used by several service discovery approaches. In this section we will examine some of them.

Service Location Protocol (SLP)

The service location protocol (SLP) is an example of centralized directory-based solution, and is now an IETF standard (Guttman, Perkins, Veizades, & Day, 1999). The current version is SLP Version 2 (SLPv2). The SLP uses DHCP options, or UDP-based multicasting to locate the service directory (known as directory agent (DA)), without manual configuration on individual clients and services (known as user agents (UAs), service agents (SAs) respectively). A multicast convergence algorithm is adopted in SLP to enhance multicast reliability.

Service registration and lookup are performed through UDP-based unicast communication between UAs/SAs and DAs. In addition, SLP can operate without DAs. In this mode, SLP works in the same way as the broadcast model. A service in SLP is described with service type in the form of a character string, the version, the URL as server address, and a set of attribute definitions in the form of key-value pairs.

To improve performance and scalability, more DAs can be deployed in network. However, SLPv2 does not provide any synchronization mechanisms to keep DAs consistent, but leaves this responsibility to SAs which should register with each DA they detect. Recently, (Zhao & Guttman, 2000) proposed a mesh enhancement for DAs to share known services between one another. Each SA needs to register only with a single DA, and its registration is automatically propagated among DAs.

Generally, SLP is a flexible IP-based service discovery protocol which can operate in networks ranging from a single LAN to an enterprise network. However, it is intended to function within networks under cooperative administrative control, and thus does not scale for the Internet.

JINI

Sun's JINI provides a similar architecture as SLP for delivering services in a network (Sun Microsystems Inc., 2003), but it is tightly bound to the Java environment and needs Java Virtual Machine (JVM) support. The protocols in JINI are implemented as Java APIs. For this reason, the JINI client is not as lightweight as the SLP client. However, JINI is more than a discovery protocol. It provides further facilities for service invocation, for transaction, and for distributed events.

INS

Adjie-Winoto, Schwartz, Balakrishnan, and Lilley, (1999) proposes a resource discovery system named *intentional naming system* (INS). The main idea is that resources or services are named using an ordered list of attribute-value pairs. Since service characteristics can be described by the service name itself, the service discovery procedure is equal to name resolving which is accompanied by the *intentional name resolver* (INR). The INR is actually a service directory that holds the global knowledge about names in

the whole network. INS is different from other naming services (e.g., DNS), in that the name describes service attributes and values, rather than simple network locations of objects.

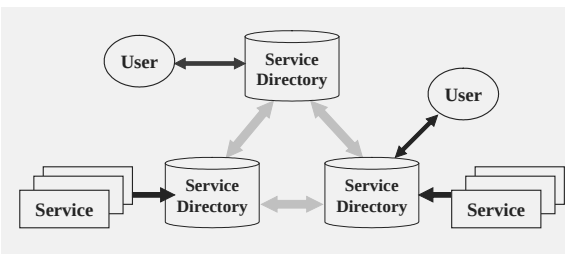
In conclusion, most centralized directory-based architectures have been designed for local networks or enterprise-wide networks which are under a common administration. The primary issue for these systems is scalability. As the number of services and clients increases, a centralized directory, even replicated, will not be feasible to accommodate a large number of registrations and lookups. In this context, the distributed repositories model has been suggested.

Distributed Service Directories Model

In the distributed directories model, the whole service domain is split into partitions, possibly according to organizational boundary, network topology, geographic locations etc. In each partition, there are one or more directories. The conceptual scheme of the distributed directories model is shown in Figure 3. The distributed directories model is different from the centralized directory model in that no directory has a complete global view of services available in the entire domain. Each directory holds only a collection of services in its partition, and is responsible for interaction with clients and services in the partition.

The service registration and query submission in the distributed model remain similar to that in the centralized directory model. But the service search operation becomes more complicated. If required services can be found by local directories, the discovery procedure is akin to that in the centralized directory model. But if not, the directories in other partitions should be asked, to ensure that a client can discover any service offers in the entire domain.

Figure 3. Distributed directories model



The directories in this model are organized in some way to achieve cooperation. As stated in (Wang, 2003), the directories can be organized in a hierarchy structure or in a mesh structure. While in the hierarchy structure there is a "belong to" relationship between directly connected directories, directories in the mesh architecture are organized in a flat interconnected form without hierarchy. The interconnection structure might have strong implications on query routing. In the hierarchy structure queries are passed along the hierarchy, either upward or downward, thus the routing path is inherently loop free. But the rigid hierarchy obstructs to shortcut the routing path in some cases. On the other hand, the mesh structure is advantageous for optimizing the routing path, but might rely on some mechanisms to avoid loop circles or repeated queries.

A typical example of distributed directories-based architecture is **service discovery service (SDS)**, developed in Berkeley (Hodes, Czerwinski, Zhao, Joseph, & Katz, 2002). The SDS is based on the hierarchy model which is maintained by periodic "heartbeat" messages between parent and child nodes. Each SDS server pushes service announcements to its parent. By this means, each SDS server gathers a complete view of all services present in its underlying tree. The significant feature of SDS is the hierarchical structure with lossy aggregation to achieve better scalability and reachability. The SDS server applies multiple hash functions (e.g., MD5), to various subsets of tags in the service description and uses the results to set bits in a fixed-size bit vector. The parent node ORs all bit vectors from its children to summarize available services in the underlying tree.

The hierarchical structure with lossy aggregation helps SDS to reach better scalability, while ensuring users to be able to discover all services on all servers. However, the SDS is more favorable for applying in stationary network environments since it requires additional overheads to maintain the hierarchical structure and to propagate index updates. If services change attributes rapidly or join/leave frequently, it will generate too much communication burden. Moreover, the OR-operation during aggregation may cause "false positive" answers in query routing. Although it does not sacrifice correctness, it will lead to unneeded additional query forwarding.

The media gateway discovery protocol (MEGADIP) is developed especially for discovering media gateways that act as proxy for transforming or caching data between media source and end users (Xu, Nahrstedt, & Wichadakul, 2000). In MEGADIP the discovery procedure starts from the local directory, and forwards the query to directories along the routing path of the network layer between media source and destination. This idea is driven by the heuristics that a media gateway on or close to the end-to-end path is likely to find more bandwidth and/or to incur smaller end-to-end delay.

Other Issues in Service Discovery

The architectural models and various approaches presented above solved the service discovery problem to some extent. However, in order to let users comfortably and effectively locate mobile multimedia services and contents, there are still some issues to be addressed. From our point of view, interoperability, asynchronous service discovery, and semantic service discovery are the most important.

Interoperability

As previously stated, a number of service discovery approaches have been proposed. Despite that most of them provide similar functionality, namely automatically discovering services based on service characteristics, they have different features and are not compatible with each other. This incompatibility is one of the biggest obstacles for mobile users to really benefit from service discovery. From our point of view, it is more useful to make different approaches interoperable, than to design a new protocol to cover functionalities of existing protocols. So far, some solutions have been proposed to bridge service discovery mechanisms, but they are limited to pair-wise bridges, such as JINI to SLP (Guttman & Kempf, 1999). Authors in Friday, Davies, and Catterall (2001) proposed a general solution on a modified form of the Structured Query Language (SQL). However, no implementation details are presented in the paper. More generally, Wang and Seitz (2002) addressed this issue by providing an intermediary layer between mobile users and underlying service discovery protocols. The intermediary layer on the one hand provides clients with a general consistent view of service configuration and a universal means to formulate search requests, on the other hand is capable of talking with various types of service discovery protocols and handling service requests from users.

Asynchronous Service Discovery

Apart from the heterogeneous environments, most of the existing approaches rarely take the issues of thin client and poor wireless link into consideration. For example, synchronous operation is one of the intrinsic natures of most existing service discovery approaches, such as SLP, Jini, and SDS. Although synchronous operation simplifies protocol and application design, it is fastidious for mobile environments. The unexpected but frequent disconnections and possible long delay of wireless link greatly influence the usefulness and efficiency of synchronous calls. To relax the communication restrains in wireless environments, (Wang & Seitz, 2002) proposed

in their CHAPLET system an approach to achieve asynchronous service discovery by adopting mobile agents. The asynchronous service discovery allows mobile users to submit a service request, without having to wait for results, nor continuously keeping the permanently active connection in the process of service discovery.

Semantic Service Discovery

Most existing service discovery approaches support only syntactic-level searching (i.e., based on attribute comparison and exact value matching). However, it is often insufficient to represent a broad range of multimedia services in real world, and lacks of capability to apply inexact matching rules. Therefore, there is need to discover services in a semantic manner. Chakraborty, Perich, Avancha, and Joshi (2001) proposes in the DReggie project to use the features of DAML to reason about the capabilities and functionality of different services. They designed a DAML-based language to describe service functionality and capability, enhanced the Jini Lookup Service to enable semantic matching process, and provided a reasoning engine based on Prolog. Yang (2001) presents a centralized directory-based framework for semantic service discovery. However, the semantic-based service discovery is still in its infancy. To promote wide development of semantic service discovery, more research efforts should be devoted.

DISCOVERING MULTIMEDIA SERVICES AND CONTENTS IN AD HOC ENVIRONMENTS

Overview

There are two well-known basic variants of mobile communication networks: infrastructure-based networks and ad hoc networks. Mobility support described in the previous sections relies on the existence of some infrastructure. A mobile node in the infrastructure-based networks communicates with other nodes through the access points which act as bridge to other mobile nodes or wired networks. Normally, there is no direct communication between mobile nodes. Compared to infrastructure-based networks, ad hoc networks do not need any infrastructure to work. Nodes in ad hoc networks can communicate if they can reach each other directly or if intermediate nodes can forward the message. In recent years, mobile ad hoc networks are gaining more and more interest both in research and industry. In this section we will present some typical approaches that enable discover and locate mobile multimedia services and contents in ad hoc environments. First we present broadcast-based approaches, and then the geographic service location approach is discussed. Next, a cluster-based approach is introduced. Finally, we present a new service or content location solution that addresses the scalability problem in multi-hop ad hoc networks.

Broadcast-Based Approaches

Considering the fact that no infrastructure is available in ad hoc environments, service directory-based solutions are unusable for service discovery in ad hoc networks. Instead, assuming that network supports broadcasting, service discovery through broadcast is one of most widely adopted solutions. Two broadcast-based approaches are possible: (1) broadcasting client requests and (2) broadcasting service announcements. In the first approach, clients broadcast their requests to all the nodes in the ad hoc network. Servers hosting requested services reply back to the clients. In the second approach, servers broadcast their services to all the nodes in the network. Each client is thus informed about the location of every service in the ad hoc network. Since these both approaches are mainly based on broadcasting, their efficiency strongly depends on the broadcast efficiency. The service location

problem in that context can be reduced to the broadcast problem in ad hoc networks. For this reason, in the following, we present a summary of proposed approaches for broadcasting in ad hoc networks. These broadcast approaches are not designed specifically for service location but we believe that a broadcast-based service location protocol has to be informed about how broadcast is carried out. This will help in deploying a cross layer-based service location protocol.

The broadcast techniques can be categorized into four families: Williams and Camp (2002), simple flooding, Jetcheva, Hu, Maltz, and Johnson (2001), probabilistic broadcast, Tseng, Ni, Chen, and Sheu (1999), location-based broadcast, and neighbor information broadcast, Lim and Kim (2000) and Peng and Lu (2000). Flooding represents a simple mechanism that can be deployed in mobile ad hoc networks. Using flooding, a node having a packet to be broadcasted sends this packet to his neighbors who have to retransmit it to their own neighbors. Every node receiving the packet for the first time has to retransmit it. To reduce the number of transmissions used in broadcasting, other broadcast approaches are proposed. The probabilistic broadcast is similar to flooding except that nodes have to retransmit the broadcast packet with a predetermined probability. Randomly choosing the nodes that have to retransmit can improve the bandwidth use without influencing the reachability. In the case of location-based broadcast techniques, a node x retransmits the broadcast packet received from a node y only if the distance between x and y exceeds a specific threshold.

The information on the neighborhood can also be used to minimize the number of nodes participating in the broadcast packet retransmission. Lim and Kim (2000) uses the information about the one hop neighborhoods. Node A, receiving a broadcast packet from node B, compares its neighbors to those of B. It retransmits the broadcast packet only if there are new neighbors that will be covered and that will receive the broadcast packet. Other broadcast protocols are based on the 2 hop neighborhood information. The protocol used in Peng and Lu (2000) is similar to the one proposed in Lim and Kim (2000). The difference is that in Lim and Kim (2000) the neighborhood information is sent within HELLO packets, whereas in Peng and Lu (2000), the neighborhood information is enclosed within the broadcast packet.

The study carried out in Williams and Camp (2002) showed that the probabilistic and location broadcast protocols are not scalable in terms of the number of broadcast packet retransmissions. The neighborhood-based broadcast techniques perform better by minimizing the number of nodes participating to the broadcast packet retransmission. The most significant disadvantage of these protocols is that they are sensitive to mobility.

Geographic Service Location Approaches

A more interesting service location approach than broadcasting the whole network is to restrict broadcasting to certain regions. These regions can be delimited on the basis of predefined trajectories. In fact, recently, geometric trajectories are proposed to be used for routing (Nath & Niculeson, 2003) and content location in location-aware ad hoc networks (Aydin & Shen, 2002; Tchakarov & Vaidya, 2004). Aydin and Shen (2002) and Tchakarov and Vaidya (2004) are closely related where content advertisements and queries are propagated along four geographical directions based on the physical location information of the nodes. At the intersection point of the advertising and query trajectories the queries will be resolved. Moreover, Tchakarov and Vaidya (2004) improves the performance by suppressing update messages from duplicate resources. However, basically they still rely on propagating advertisements and queries through the network.

Cluster-Based Solutions

Besides enhancements in broadcast, clustering can also be used to improve the performance of service discovery in mobile ad hoc networks. An interesting cluster-based service location approach designed for ad hoc networks is proposed in Koubaa and Fleury (2001) and Koubaa (2003). The proposed approach involves four phases: (1) the servers providing services are organized within clusters by using a clustering protocol. The cluster-heads, elected on the basis of an election protocol, have the role of registering the addresses of the servers in their neighborhoods (clusters). (2) A reactive multicast structure gathering the cluster-heads to which participate the cluster-heads of the created clusters is formed at the application layer. Each client or a server in the network is either a part of this structure or one hop away from at least one of the multicast structure members. (3) Clients send their request inside this multicast structure. (4) An aggregation protocol is used to send the replies of the cluster-heads within the multicast structure. The aim of the aggregation protocol is to avoid using different unicast paths for reply transmission by using the shared paths of the multicast structure.

A study comparing broadcast approaches to the cluster-based approach is carried out in Koubaa and Fleury (2002). This comparison study showed that clustering reduces the overhead needed for clients to send their requests and for servers to send back their replies. This reduction is noticeable when we increase the number of clients, the number of servers, and the number of nodes in the ad hoc network. The multicast structure used in Koubaa (2003) consists of a mesh structure which is more robust than a tree structure. The density of the mesh structure is dynamically adapted to the number of clients using it. The key idea of this dynamic density mesh structure is that the maintaining of the mesh is restricted to some clients called effective clients. Indeed, when the network is dense or the number of clients is high there is no need that all clients participate the multicast structure maintaining. This new mesh structuring approach is compared to ODMRP (Koubaa, 2003) where all the multicast users participate in the mesh maintaining. The comparison study showed that the proposed dynamic density mesh is more efficient than ODMRP. Compared to the tree-based multicast structure, the mesh-based multicast structure shows better server reply reachability performance but using more bandwidth.

Scalability Issue in Service Location

Currently it is well known that ad hoc networks are not scalable due to their limited capacity. The scalability problem is mainly related to the specific characteristics of the radio medium limiting the effective ad hoc network capacity. Even though, we think that designing specific solutions for scalable networks can help us at defining how much scalable is an ad hoc network. In the context of service location, authors in Koubaa and Wang (2004) state the problem of scalable service location in ad hoc networks and propose a new solution inspired by peer-to-peer networks called HCLP (hybrid content location protocol). The main technical highlights in approaching this goal include: (1) the hash function for relating content to zone, (2) recursive network decomposition and recomposition, and (3) content dissemination and location-based on geographical properties.

The hashing technique is used in HCLP both for disseminating and locating contents. But unlike the approaches in peer-to-peer systems where the content is mapped to a unique node, the hash function in HCLP maps the content to a certain zone of the network. A zone means in HCLP a certain geographical area in the network. The first reason for mapping content into zone, i.e. a subset of nodes, instead of an individual node, is mainly due to the fact that it could be expensive in radio mobile environments to maintain a predefined rigid structure between nodes for routing adver-

tisements and queries. For example, in Stoica, Morris, Karger, Kaashoek, and Balakrishnan (2001), each joining and leaving of nodes has to lead to an adjustment of the Chord ring. Moreover, the fact that the routing in ad hoc networks is far less efficient and less robust than in fixed networks makes the adjustments more costly if there is node movement. The second reason for relating content to zone is that it is more robust to host a content within many nodes inside a zone than to host it within an individual node.

The underlying idea of network decomposition in HCLP is to achieve load distribution by maintaining the zone structure. It is well known that if the number of the nodes and contents in an unstructured and decentralized zone is beyond a certain limit, the network overhead related to content advertisement/location would become unsatisfactory. Therefore, to ensure a favorable performance and to achieve a better load distribution in HCLP, a zone could be divided into sub-zones recursively if the cost related to content advertisement/location using unstructured approaches in the zone exceeds a certain threshold.

To enable network decomposition in different zones a protocol is deployed to make it possible to nodes on the perimeter of the network exchanging their geographical locations. This will help estimating the position of the centre of the network. Knowing the locations of the nodes on the perimeter and the location of the network centre, a simple decomposition of the network into four zones is used. Each of these zones can also be decomposed again into four zones, etc.

In HCLP, for disseminating or locating a content in the network, a user first sends out its announcement or query request along one of four geographical directions (north, south, east, and west) based on geographic routing. In a dense network, the announcement or the request will then be caught on the routing path by a node that knows the central region of the network, in the worst case by a perimeter node on the network boundary. This node will then redirect the request into the direction of the central region, again by geographic routing. The node that belongs to the central region and receives this query message has the responsibility to decide whether to resolve the request directly within the zone or whether to redirect the request to the next level of the zone hierarchy, until the content is discovered.

Such a content dissemination and location scheme works completely decentralized. Moreover, only a small portion of nodes is involved in routing and resolving advertisement or query messages. Because not all nodes are necessary for maintaining routing information nor a global knowledge of the whole network is required, HCLP can be expected to be well scalable to large ad hoc networks.

CONCLUSION

The prevalence of portable devices and wide deployment of easily accessible mobile networks promote the usage of mobile multimedia services. In order to facilitate effectively and efficiently discovering desirable mobile multimedia services and contents, many research efforts have been done. In this chapter, we discussed existing and ongoing research work in the service discovery field both for infrastructure-based mobile networks and mobile ad hoc networks. We introduced three main architectural models and related approaches for service discovery in infrastructure networks, and pointed out some emerging trends. For discovering services and contents in ad hoc networks, we presented and compared proposed approaches based on either broadcast or cluster, and discussed the scalability issue in detail. We believe that service discovery will play an important role for successful development and deployment of mobile multimedia services.

KEY TERMS

Aggregation: A process of grouping distinct data. Two different packets containing different data can be aggregated into a single packet holding the aggregated data.

Broadcast: A communication method that sends a packet to all other connected nodes on the network. With broadcast, data comes from one source and goes to all other connected sources at the same time.

Clustering: Identifying a subset of nodes within the network and vest them with the responsibility of being a cluster-head of certain nodes in their proximity.

Hash: Computing an address to look for an item by applying a mathematical function to a key for that item.

Mobile Ad Hoc Network: A kind of self-configuring mobile network connected by wireless links where stations or devices communicate directly and not via an access point. The nodes are free to move randomly and organize themselves arbitrarily, thus, the network's topology may change rapidly and unpredictably.

Multicast: A communication method that sends a packet to a specific group of hosts. With

multicast, a message is sent to multiple destinations simultaneously using the most efficient strategy that delivers the messages over each link of the network only once and only creates copies when the links to the destinations split.

Scalability: The ability to expand a computing solution to support large numbers of components without impacting performance.

Service: An abstraction function unit with clearly defined interfaces that performs a specific functionality. Users, applications, or other services can use the service functionality through well-known service interfaces without having to know how it is implemented.

Service Directory: An entity in service discovery architecture that collects and stores information about a set of services within a certain scope, which is used for searching and/or comparing services during the service discovery procedure. Service directory is also known as service repository or directory agent. Service directory can be organized in central or distributed manner.

Service Discovery: The activity to automatically find out servers in the network based on the given service type and service attributes. The service discovery is, therefore, a mapping from service type and attributes to the set of servers.

Nitin Mittal
Nokia Pte Ltd, Singapore

ABSTRACT

The evolution in mobile messaging and mobile devices has made it possible to provide multimedia rich messaging capabilities to personal digital assistants (PDAs). The need for this arises simply because mobile service providers want to provide an enhanced messaging experience to the user. It also opens up new avenues for business, such as a shopping mall scenario. This chapter discusses the development of a multimedia messaging client for a PDA and a kiosk providing multimedia messages composition, search, share, and sending capabilities. This chapter also discusses the various messaging technologies, enabling wireless technologies, and the peer-to-peer model. The peer-to-peer technology used was Jxta, an XML-based and language agnostic peer-to-peer platform specification from Sun Microsystems. The peers (PDA client and the kiosk) were implemented using the application programming interfaces provided by the Personal Java reference implementation and the Jxta platform's Personal Java port.

INTRODUCTION

Over the years, mobile messaging has become an essential means of communication and is going to be even more so with the merging of the Internet and mobile networks. The ability to message from a phone to a computer on the Internet and vice versa is making messaging a powerful means of communication (Yeo, Hui, Soon, & Lau, 2001).

Mobile messaging is going through a gestation period (Tan, Hui, & Lau, 2001). Beginning with the enormously popular short message service (SMS) for simple text messages, the exciting enhanced message service (EMS) for illustrated text messages with sound entered the market as the second step. Multimedia messaging service (MMS) will become the ultimate messaging application, allowing users to create unique messages using various types of multimedia.

Initially, only mobile phones will support multimedia messaging. Personal digital assistants (PDA) are becoming very common and it is natural to think of putting this capability in them as well. PDAs have a larger form factor, memory footprint, and more powerful processors

and as a result would provide a richer messaging experience.

This chapter discusses the development of a multimedia messaging client for a PDA and a kiosk providing multimedia messages composition, search, share, and sending capabilities. Various messaging technologies, enabling wireless technologies, and the peer-to-peer model were also discussed and evaluated in this chapter. We substantiate the ideas discussed in this chapter with a description of the design and implementation of an MMS PDA client application with specific references to a shopping mall scenario.

BACKGROUND

Short Messaging Service

Text messaging uses the short messaging service (100-200 characters in length) and involves sending text messages between phones. Examples include "C U L8ER" and "OK. AT FLAT OR OFFICE." It is quick and dirty, hard to use the keypad, abrupt, punctuation challenged, and incredibly useful and popular. Text messaging also has a lot of advantages such as convenience, available on all phones, and discrete.

Text messaging is something that is most prevalent in the youth market and especially teenagers, who are able to manipulate the difficulty of entering text with the mobile phone keypad. In fact, it is suspected that this steep learning curve and the necessary insider knowledge are some of the things that appeal to the youngsters (Bennett & Weill, 1997).

SMS Advantages

Today's SMS has several advantages inherent in its fundamental features:

- **Store and forward.** This means that in the case that the recipient is not available, the short message is stored. Once the data is prepared and ready to send, SMS has advantages over packet data in that the burden of delivering the data is on the SMS center rather than the end user. The transaction costs incurred by the sender using SMS are therefore likely to be lower than a GPRS transaction.
- **Confirmation of delivery.** This means that the user knows that the short message has arrived. In the circuit switched data environment, there is an end-to-end connection and therefore the user knows that a connection has been established and the data is being transferred. In a GPRS environment, however, the concept is "always on" and this requires the user to find out whether the data has been sent or received.

SMS Disadvantages

However, today's SMS also has several disadvantages:

- **Limited message length.** The unit short message length is currently limited to 140 octets because of limitations in the signalling layer. It would be preferable to have a length that is several times this magnitude. Packet data services such as GPRS simplify non-voice transactions over mobile networks because the amount of data that can be communicated in any one session is significantly higher.
- **Inflexible message structure.** The structure of the SMS protocol data unit as defined in the GSM 03.40 standard is inflexible. The data coding scheme, origination address, protocol identifier, and other header fields are fixed—this has constrained the number of possible scenarios that can be indicated when developing applications.
- **Relatively slow signalling channel.** The latency turnaround time of services such

as GPRS and unstructured supplementary services data (USSD) tends to be faster than that for SMS. The signalling channel is used for several other purposes besides SMS, such as locating phones and managing call completion. Indeed, as SMS traffic volume grows, network operators have expressed some concern about potential service outages due to the overuse of and corresponding degradation in the scarce signalling resources.

- **Always store and forward.** Today's SMS is designed such that every short message always passes through the SMS center. Variations on this have been discussed at the UMTS committee level, such as forwarding messages and optionally storing them: immediately attempt delivery and if the message cannot be delivered, then store it. This reduces the processing power needed by the SMS center.

Enhanced Messaging Service

The enhanced messaging service (EMS) is the ability to send a combination of simple melodies, pictures, sounds, animations, modified text, and standard text as an integrated message for display on an EMS-compliant handset. For example, a simple black-and-white image could be displayed along with some text and a melody could be played at the same time. EMS is an enhancement to SMS but is very similar to SMS in terms of using the store-and-forward SMS centers and the signalling channel.

EMS Advantages

With the new, powerful EMS functionality, mobile phone users can add life to SMS text messaging in the form of pictures, animations, sound, and formatted text. As well as messaging, users will enjoy collecting and swapping pictures and ring signals and other melodies, downloading them from the Internet, or editing them directly on the phone.

- **Familiar user interface (UI).** Users will find EMS as easy to use as SMS. EMS provides a familiar user interface and compatibility with existing phones.
- **Compatible with SMS standards.** An EMS message can be sent to a mobile phone that does not support EMS or only partially supports EMS. All the EMS elements are located in the message header. A receiving phone that does not support the standard will ignore the EMS contents. Only the text message will be displayed to the receiver.
- **No new network infrastructure needed.** The beauty with EMS is that it uses existing SMS infrastructure and industry standards, keeping investments to a minimum for operators.
- **Concatenated messages.** SMS concatenation—stringing several short messages together—will be the key technical feature to enable the enhanced messaging service for the simple reason that complicated enhanced message designs, such as sending every alternate character in bold format, would occupy a large number of octets.

Multimedia Messaging Service

Overview of MMS

The multimedia messaging service, as its name suggests, is the ability to send and receive messages comprised of a combination of text, sounds, images, and video to MMS-capable handsets (MMS architecture, 2002). The trends for the growth in MMS are taking place at all levels within GSM (Patel & Gaffney, 1997), enabling technologies such as GPRS, EDGE, 3G, Bluetooth (http://www.bluetooth.com/), and wireless access protocol (WAP; WAP & MMS specifications, 2002).

MMS, according to the 3GPP standards (3GPP TS 23.140, 2002) is "a new service, which has no direct equivalent in the previous ETSI/GSM world or in the fixed network world." Here is an introduction to the features of this innovative new service:

- MMS is a service environment that allows different kinds of services to be offered, especially those that can exploit different media, multimedia, and multiple media.
- MMS will enable messages to be sent and received using lots of different media, including text, images, audio, and video.
- As more advanced media become available, more content-rich applications and services can be offered using the MMS service environment without any changes.
- The multimedia messaging service (MMS) introduces new messaging platforms to mobile networks in order to enable MMS. These platforms are the MMS relay, MMS server, MMS user databases, and new WAP gateways.
- MMS will require not only new network infrastructure but also new MMS-compliant terminals. MMS will not be compatible with old terminals, which means that before it can be widely used, MMS terminals must reach a certain penetration.

MMS Versus E-Mail

Four key areas best illustrate the differences between MMS and e-mail messages:

- **Message creation.** Conventional e-mail evolved from a simple text-based communication tool to include multimedia content, primarily in the form of attachments. A mobile device's form factor and the use of mobile data service, such as e-mail, become extremely unwieldy for the end user. MMS has been standardized specifically to take the limitations of mobile devices and the mobile end-users' needs into account.
- **Message delivery.** Conventional e-mail is designed around a store-and-retrieve model, whereas technologies such as SMS and MMS operate on a store-and-forward model. When sending a message using the former model, the sender must wait for the receiver to come online and access the network to retrieve the message. With the MMS model the message is stored and "pushed" or forwarded to the receiver immediately or as soon as the receiver comes online.
- **Messaging interoperability.** Today, e-mails can contain numerous and varied media formats and/or types. Each media type generally requires tools/plug-ins to render that media usable. In the desktop environment these tools are available locally or via the intra/Internet. This is not the case for the mobile subscriber due to the limited set of media-rendering capabilities available on mobile devices.
- **Message billing.** Conventional e-mail billing has relied on the subscription and/or access time model for billing the subscriber, resulting in little or no revenue for the service providers in some markets. SMS, however, has worked using a per-message billing model. Since MMS is the service evolution of SMS, mobile operators can apply SMS-like billing models to MMS without adverse customer reaction.

Implications of SMS on MMS

The current short message service has some unique advantages that other non-voice services do not have, such as store and forward and confirmation of message delivery. However, SMS also has some disadvantages, such as limited message length, inflexible message addressing structures, and signalling channel slowness.

Table 1. SMS versus MMS

Feature	**SMS**	**MMS**
Store and Forward (non-real-time)	Yes	Yes
Confirmation of message delivery	Yes	Yes
Communications type	P erson to person	Person to person
Media supported	T ext plus binary	Multiple— text, voice, video
Delivery mechanism	Signalling channel	Data traffic channel
Protocols	SMS specific, e.g., SMPP	General Internet, e.g., MIME, SMTP
Platforms	SMS center M	MS relay plus others
Applications	Simple person to person	Still images

Implications of EMS on MMS

Messaging will certainly develop beyond SMS. It is clear that an elegant solution like EMS that builds on simple text messaging and adds sound and simple images is a useful and powerful development that takes us beyond the limited reach of smart messaging services. It is clear that multimedia messaging service provides an ideal migration path to take advantage of the capacity and bandwidth that 3G/UMTS networks supply.

To summarise, MMS offers the content richness of e-mail and the instantaneous delivery of SMS messaging. While e-mail provides greater levels of utility, it fails to provide the instantaneous sharing and presentational capabilities needed to make it truly the mobile mass-market service. The strength of MMS in these areas make MMS the premium mass-market messaging service in 2.5G and 3G networks.

P2P MODEL AND JXTA

The previous section provides a discussion on the various messaging technologies, which are only the tools that MMS peers use to deliver their contents. What is more important is the distributed peer-to-peer model, which allows various MMS peers to discover and communicate with each other. This section gives a brief overview of distributed computing models and describes in detail one peer-to-peer technology, i.e., Jxta.

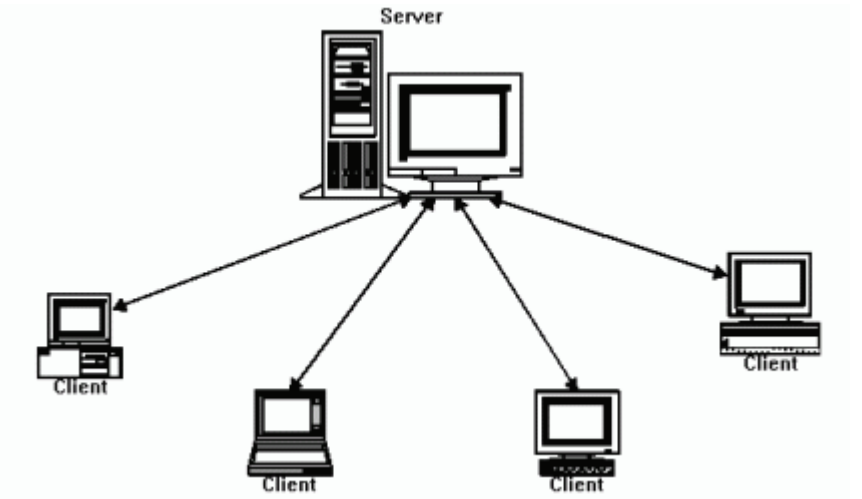
Distributed Computing Models

Overview of Client-Server Model

Today, the most common distributed computing model is the client-server model (Chambers, Duce, & Jones, 1984). Figure 1 depicts the typical client-server architecture.

In the client-server architecture, clients request services and servers provide those services. A variety of servers exist in today's Internet––Web servers, mail servers, FTP servers, etc. The client-server architecture is an example of a centralized architecture, where the whole network depends on central points to provide services. Regardless of the number of clients, the network can exist only if a server exists (Berson, 1992).

Figure 1. Client-server model

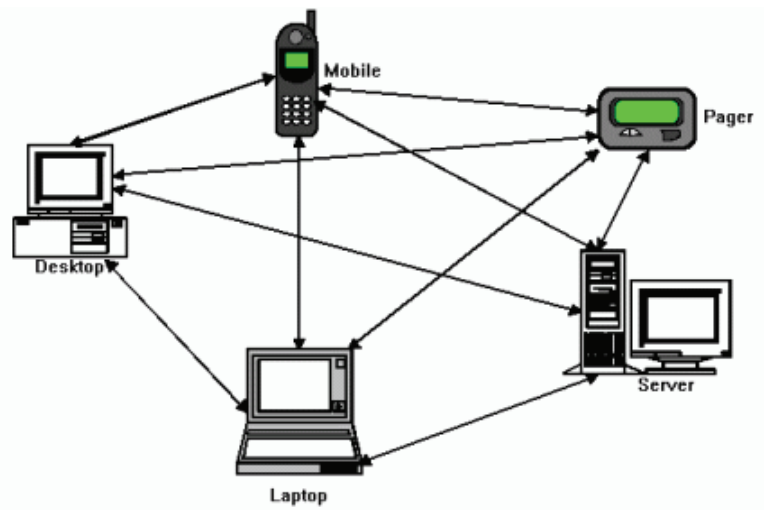


Overview of Peer-to-Peer Model

Like the client-server architecture, P2P is also a distributed computing model (Yemini, 1987). However, the P2P architecture is a decentralized architecture where neither client nor server status exists in a network (Madron, 1993). Every entity in the network, referred to as a *peer*, has equal status, meaning that an entity can either request a service (a client trait) or provide a service (a server trait). Figure 2 illustrates a P2P network.

Though peers all have equal status in the network, they don't all necessarily have equal physical capabilities. A P2P network might consist of peers with varying capabilities, from mobile devices to mainframes (Budiarto & Masahiko, 2002). A mobile peer might not be able to act as a server due to its intrinsic limitations, even though the network does not restrict it in any way.

Figure 2. P2P model



Comparison of Models

Both networking models feature advantages and disadvantages. One can visualize from Figure 1 that as a client-server network grows (i.e., as more and more clients are added), the pressure on the central point, the server, increases (giving rise to "hot spots"). As each client is added, the central point weakens and its failure can destroy the whole network.

A P2P network delivers a quite different scenario. Since every entity (or peer) in the network is an active participant, each peer contributes certain resources to the network, such as storage space and CPU cycles. As more and more peers join the network, the network's capability increases. A P2P network also differs from the client-server model in that the P2P network can be considered *alive* even if only one peer is active. The P2P network is unavailable only when no peers are active.

Jxta

Different protocols, different architectures, different implementations. That accurately describes current P2P solutions. Currently, developers use diverse methodologies and approaches to create P2P applications. Standards, abundant in the client-server world, are noticeably absent in the P2P world. To tackle this deficit, Sun developed *Jxta* (http://www.jxta.org/.).

Jxta strives to provide a base P2P infrastructure over which other P2P applications can be built (Project Jxta, 2002). This base consists of a set of protocols that are language independent, platform independent, and network agnostic. These protocols address the bare necessities for building generic P2P applications (Jxta technology overview, 2002). Designed to be simple with low overheads, the protocols target to build, to quote the Jxta vision statement, "every device with a digital heartbeat."

Jxta currently defines six protocols (Jxta protocol specification, 2002), but *not all Jxta peers are required to implement all six of them.* The number of protocols a peer implements depends on that peer's capabilities. A peer could use just one protocol. Peers can also extend or replace any protocol, depending on its particular requirements (Brookshier, 2002).

Jxta Core Building Blocks

Peer and Peer Groups. With today's limit on connectivity and available bandwidth, harnessing the entire Internet as one huge P2P network is impractical. Instead, some partitioning is

Figure 3. Jxta software architecture

Service name	Description
Pipe	The main means of communications between peers; provides an abstraction for a one-way, asynchronous conduit for information transfer.
Membership	Determines which peers belong to a peer group; handles arrival and departure of peers within a peer group.
Access	Security service for controlling access to services and resources within a peer group; a sort of security manager for the peer group.
Discovery	A way peers can discover each other, the existence of other peer groups, pipes, services, and the like.
Resolver	Allows peers to refer to each other, peer groups, pipes, or services indirectly through a reference (called an *advertisement* in Jxta lingo); the resolver binds the reference to an implementation at run time.

necessary. The logical partitioning of the physical network creates working sets of peers called *peer groups*. Peer group memberships can overlap with no restriction; in other words, any peer can belong to as many peer groups as necessary. The Jxta specification does not dictate or recommend an appropriate way of forming peer groups. In a Jxta network, a peer group is a collection of peers that share resources and services.

Jxta Services. Jxta *services* are available for shared use by peers within a peer group. In fact, a peer may join a group primarily to use the services available within that group. A set of services, called *core services,* is essential to the basic operation of a Jxta network. One instance of a core service already seen is the membership service. Table 2 shows the core services included in version 1.0 of the Jxta specification.

The initial reference implementation of project Jxta does not provide any services beyond the five listed in Table 2. Even some of the core services, such as the access service dealing with security, are implemented in a very basic way.

Pipes. One way to transfer data, files, information, code, or multimedia content between peers is through logical pipes, as defined by the Jxta specification. Jxta pipes are used to send messages (with arbitrary content) between peers. A pipe instance is, logically speaking, a resource within a peer group. The actual implementation of a pipe instance is typically through the pipe service. Unlike conventional UNIX-like systems, Jxta pipes are unidirectional and asynchronous.

Regardless of the type of pipe, the blocks of information carried though the pipe are referred to as Jxta *message*.

Messages. Jxta messages are data bundles that are passed from one peer to another through pipes. The Jxta specification is again as generic as possible here so as not to inadvertently introduce any implementation-dependent policies into the definition of a message. A message is defined to be an arbitrarily sized bundle, consisting of an envelope and a body. The envelope is in a standard format that contains:

- A header
- Source endpoint information (in URI form)
- Destination endpoint information (in URI form)
- A message digest (optional––for security purposes)

The body of a message is of arbitrary length and can contain an optional credential (for security purposes) and content.

Advertisements. Advertisements are the less obvious cousins of messages. Jxta advertisements are also XML documents. The content of an advertisement describes the properties of a Jxta component instance, such as a peer, a peer group, a pipe, or a service. *For example, a peer having access to an advertisement of another peer can try to connect directly to that other peer.* A peer having access to an advertisement of a peer group can use the advertisement to join that group. The current Internet analogue to an advertisement is the domain name and DNS record of a Web site.

JXTA Versus .NET and JINI

Jxta's XML-based messaging is similar to Microsoft's .Net and SOAP technologies. But that is a very thin foundation for comparison. As more and more third-party protocols make use of XML, it will become obvious that just using XML as a message format says nothing at all about an actual networking technology. Comparing the high-level, policy-rich, Web-services-based infrastructure that is .Net to the low-level, fundamental, policy-neutral nature of Jxta is a futile exercise.

Project Jxta and the Jini project are also fundamentally different. Both of them have some similarity in higher-level interaction, enabling true distributed computing over a network. However, the similarity abruptly ends there. Strategic differences between the two are: Jxta started life as a completely interoperable technology (any platform, any programming language, any vendor). Sun is a mere contributor in the community. Jini is a Java-centered technology that Sun will integrate and deploy strategically in future product offerings. Sun will maintain a degree of control over Jini's evolution.

MMS Kiosk and Jxta

In a P2P environment like Jxta, commonly accessed information gets replicated (the peers have a choice to keep a copy of content passing through them) and becomes available at peers fewer hops away. This avoids "hot spots" and is ideal for content sharing where the content can be of any type. For an MMS kiosk searching for multimedia messages, the situation is no different and it would thus be ideal to use a P2P framework to advertise and search for multimedia messages and media content.

A simple scenario is when a shop in a shopping mall adds more product brochures (in the form of MMS presentations) to its peer and advertises them. Subsequently, the kiosk would discover the new content and make it available to customers wishing to use the service from the kiosk. In a shopping mall this is likely to happen often as shops are always finding new ways of providing exciting offers to its customers. For example, shops providing multimedia messages for entertainment purposes would be updating their message collections often.

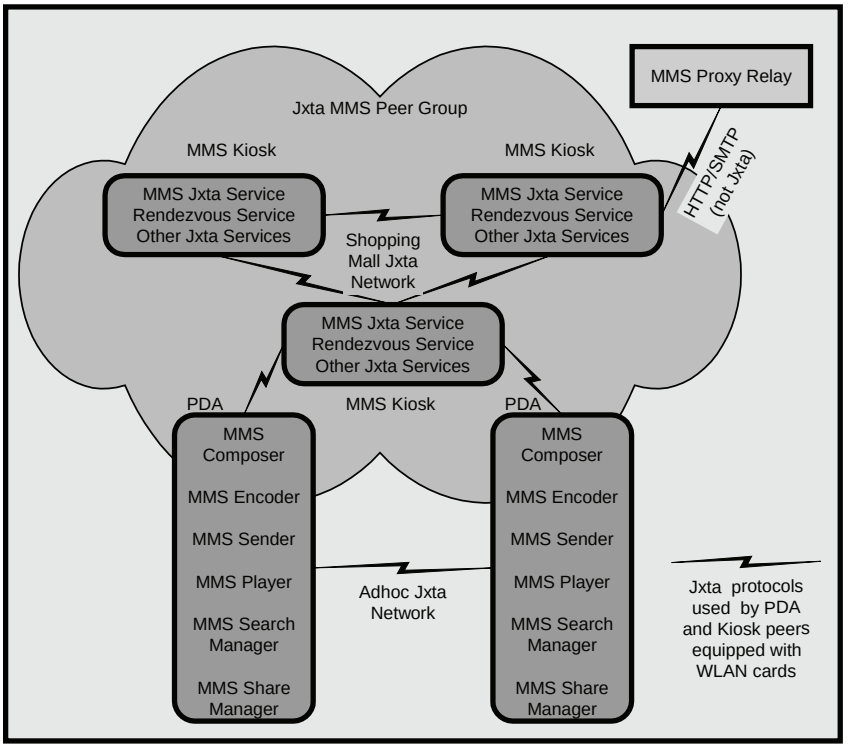
In another shopping mall scenario, a customer with a PDA walks into a shop, automatically connects to a *peer within range*, and begins searching for MMS messages and also an MMS service if it does not have the capability to connect to the MMS proxy-relay itself. In such a case, the PDA becomes a part of a peer group formed with the other customers around it. Hence, the search is not limited to the shopping mall peer-to-peer network but also to an ad hoc network created by the presence of other customers.

In a frequently changing environment like this, a P2P model like Jxta, with its dynamic resolution of peers and advertising and discovery capabilities, would be ideal to find the freshest content.

MMS Peer

Most shopping malls have information kiosks, which could be equipped with a network point and wireless service access capabilities using technologies like Bluetooth or 802.11b (IEEE 802.11, 2002). Location-specific MMS content

Figure 4. MMS peers and kiosk architecture



could be provided to customers in the vicinity of a kiosk or a shop. MMS would just be one of the many other services that can be provided at the kiosk, especially for mobile devices not connected to the cellular network or not subscribed to data services but with Bluetooth or 802.11b access.

The shops could provide product brochures, cards, postcards, pictures, comic strips, sounds, songs, etc. in the form of MMS presentations, which could be used by a customer to send to another person. The information kiosk could perform searches across the mall's network to update its multimedia message repository and provide a common contact point for all the shops in the mall.

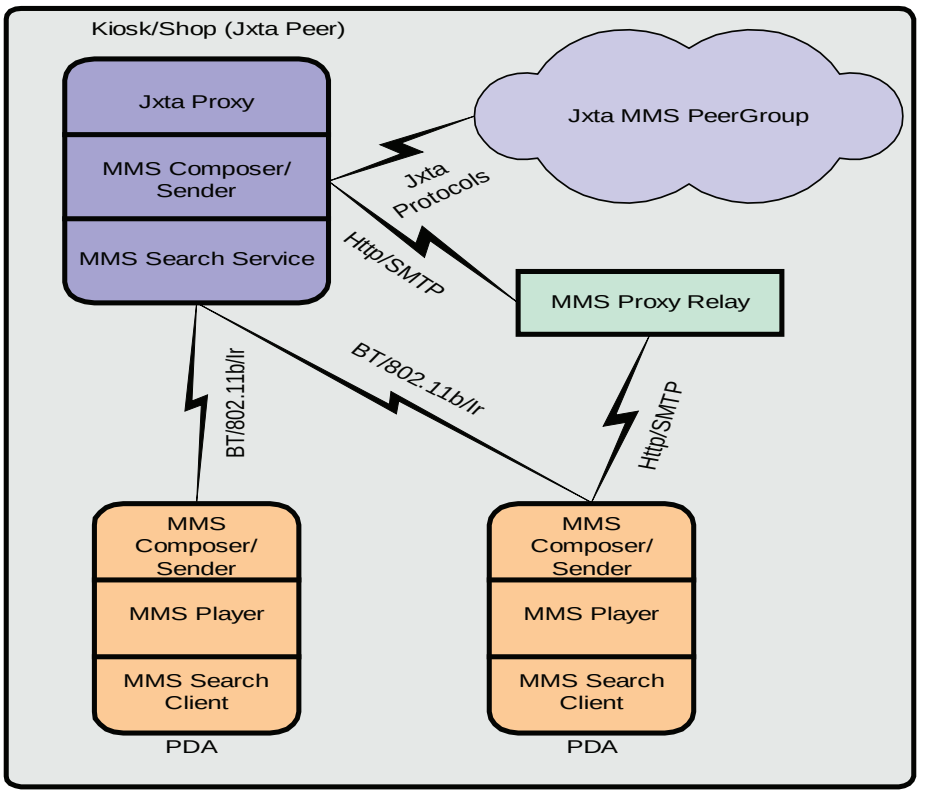
The requirement here is to provide enhanced customer service. The customer need not visit all the shops and need not verbally describe a product to another person before making a decision to buy something. Instead he or she could simply send the product brochures to the other person via MMS. These kiosks could also provide multimedia messages intended for fun and entertainment purposes and charge for them. Alternatively, shops could provide free MMS as a value-added service to their customers.

DESIGN AND IMPLEMENTATION OF MMS PEERS

Architecture I

Figure 5 shows the architecture of the whole MMS kiosk system when a PDA is incapable of running a Jxta peer. The PDA, in this architecture, is used to access the services provided by the kiosk/shop (like the MMS message search, composition, and sending). The PDA to kiosk/shop interaction is a client-server interaction. The kiosks and shops are the nodes in the P2P network here, not the customers' PDAs.

Figure 5. MMS kiosk environment architecture I



The PDA has been shown to have only an MMS composer, MMS player, and MMS sender. The MMS composer composes a message by aggregating all the media and presentation information provided by the user. The MMS sender performs a HTTP post to the MMS proxy-relay to send the message to its destination. An MMS player is also provided to the PDA client to view an MMS message before sending. The kiosk/shop is what provides the service to allow a customer to search for MMS messages and send them. The kiosk and the shops are part of a Jxta MMS peer group.

The protocols that the PDA can use to directly send to the MMS proxy are either HTTP or SMTP (if the MMS proxy-relay provides an SMTP interface). The communication between the kiosk/shop and the PDA can be over Bluetooth, IEEE 802.11b, or infrared. Infrared is not a good choice due to its very limited range (IrOBEX Specification, 2002).

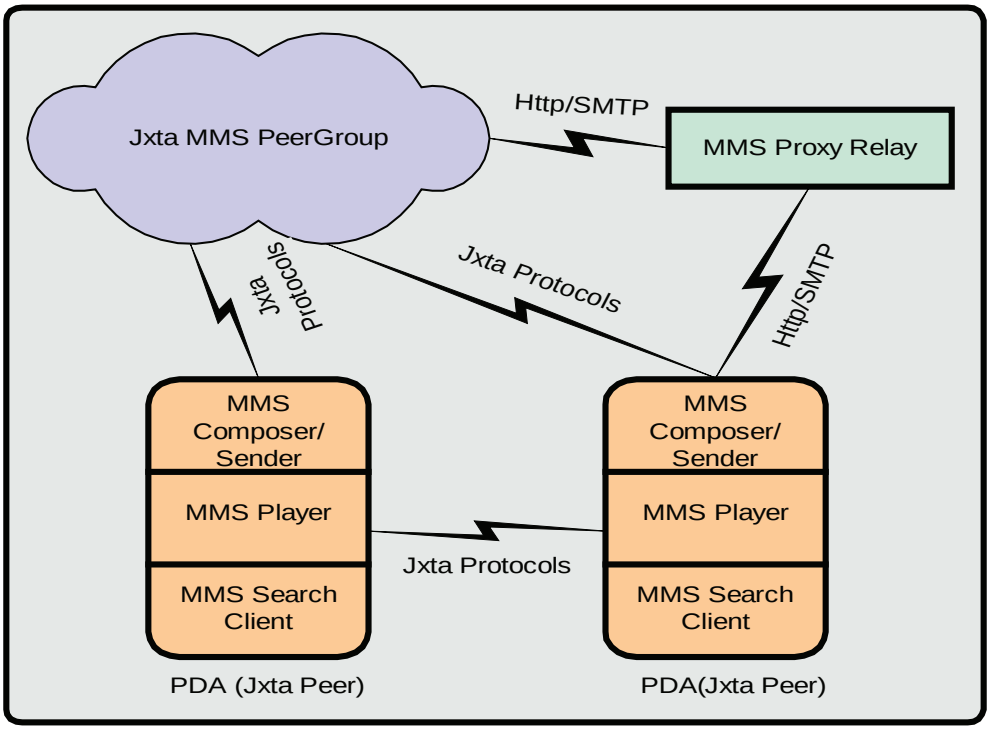
Architecture II

Figure 6 shows the final architecture due to the availability of the Jxta platform for a PDA (Jxta platform, 2002) and the P2P advantages it offers over Architecture I. Unlike Architecture I, this architecture is almost fully P2P, except the interaction between the Jxta peer and the MMS proxy-relay. This offers the advantage that a customer can become part of a peer group due to other customers around him. This opens opportunities for customers to exchange MMS messages they have on their devices.

PDA MMS Peer Design

The MMS peer on the PDA consists of four modules:

Figure 6. MMS kiosk environment architecture II



- MMS composer
- MMS encoder and sender
- MMS player
- MMS Jxta search and share

MMS Composer

This module allows a user to compose an MMS on the move (see Figure 7). It allows the user to select the media content and provide layout details and timing information for the slides of the MMS presentation. The process results in the generation of an SMIL file, which contains the presentation details of the media. Subsequently a Jar file (JAR documentation, 2002) is created with all the media files and the SMIL file. The MMS sender (in the next section) takes the Jar as its input, encodes it into an MMS, and sends it.

MMS Encoder and Sender

MMS can be sent either using HTTP Post or SMTP if the MMS proxy-relay provides both interfaces (see Figure 8). The two modes of sending the message could be chosen based on the priority of the message. Using SMTP takes longer to send, as the message has to be ultimately encoded according to MMS standards (MMS encapsulation specification, 2002). Hence, SMTP could be used to send low-priority messages.

MMS Player

The MMS player takes a Jar as input, extracts all the media and SMIL parts, and uses a SMIL parser to parse the SMIL and play it (see Figure 9). The slides in the SMIL presentation are rendered using *double buffering* (Double buffering in Java, 2002). The AMR audio is first converted to

Figure 7. MMS composer design

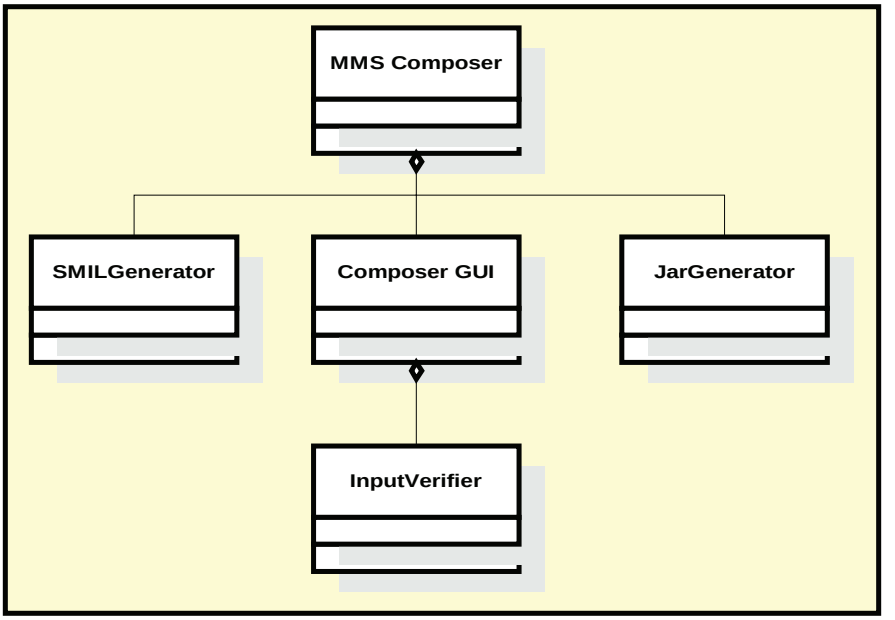


Figure 8. MMS sender design

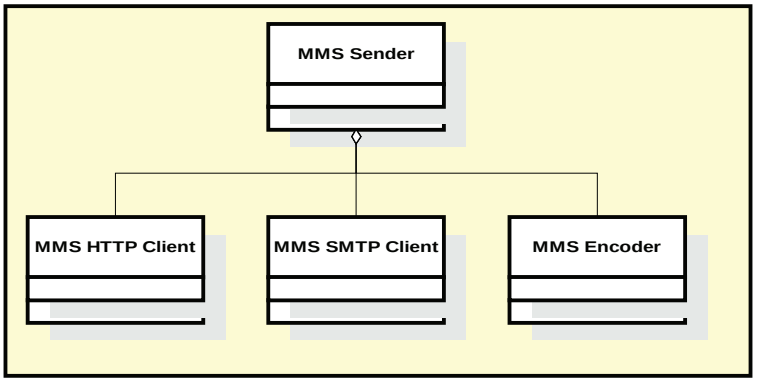


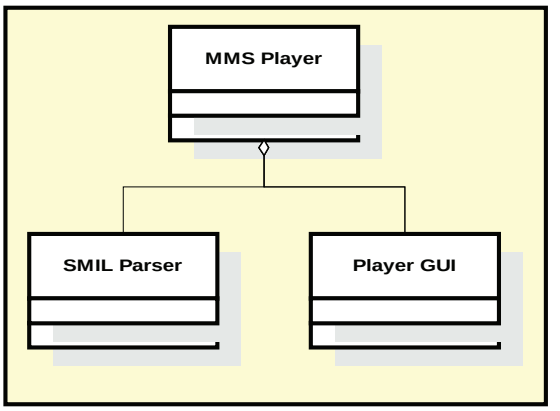
the WAV format and then played. Imelody (.imy files) files (iMelody specification, 2002) cannot be played by the application at this stage.

It was observed that some WAV files with a certain header were not playing on WinCE 3.0 but were playing on the desktop (Win 2000). The AMR to WAV converter native code was modified to take care of the change. The native code to convert and play is used via the Java Native Interface (JNI; Java Native Interface, 2002).

MMS Jxta Search and Share

The MMS application once started represents a Jxta peer. The peer becomes a member of a universal group called the net peer group. The peer then starts to discover its peers and available peer groups. The search and share module relies on two main modules called the peer group manager and the search manager (see Figure 10). The search and share uses the content management service.

Figure 9. MMS player design



A peer group manager is created after the start-up of the Jxta platform. This manager monitors and influences peer group discovery. It maintains the list of groups the peer has currently joined and allows one to join, leave, and create peer groups. The search manager is the interface to the file sharing application. The content put up locally by the peer or remotely in the peer group is described by an MMS advertisement. The MMS advertisement allows propagation along normal Jxta discovery channels.

MMS Kiosk Design

According to Architecture I, the kiosk consists of three modules: one to compose and send an MMS message, a second to search for MMS content, and a third to handle requests from the PDA. In Architecture II, the kiosk is not much different from the PDA peer except that it would also be expected to act as a rendezvous and run a MMS Jxta service described below.

MMS Jxta Service

Peers having access to the MMS proxy-relay provide the MMS Jxta service. The service is searched for by peers which do not have connection to the Internet and cannot access the MMS proxy-relay directly. The service advertisement contains the pipe advertisement so that other peers can connect to it and use it. This service should be run as a peer group service so that there is a higher chance of the availability of the service. When run as peer group service, the peers running the service rely on one peer group service advertisement instead of publishing their own for the same service.

Figure 10. MMS search and share design

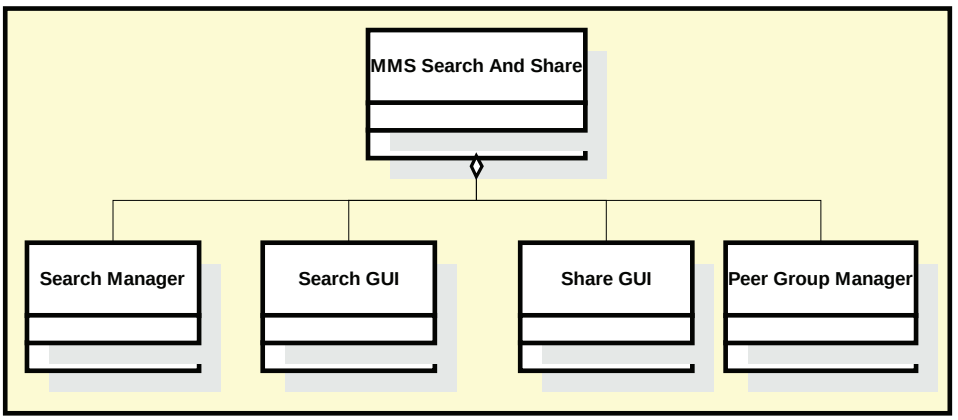


Figure 11. MMS Jxta service design

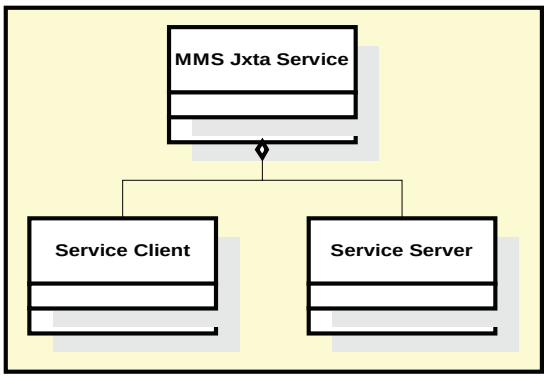

Figure 12. MMS kiosk design for Jxta-enabled PDAs

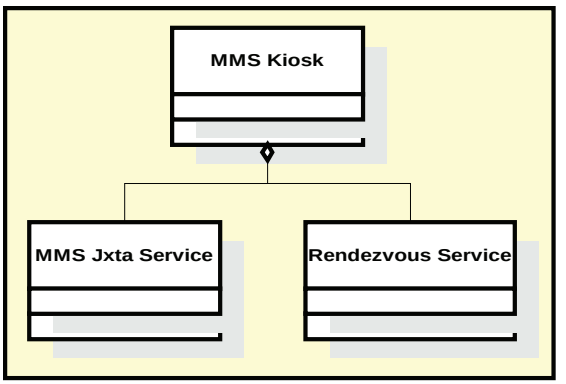

Jxta Proxy

Jxta proxy is required for devices that cannot run the Jxta core services yet. The Jxta proxy should receive the requests from the PDA client and then use the MMS search and messaging services on behalf of the PDA. It would also provide the interface to the transport protocol used between the kiosk/shop and the PDA.

Graphical User Interface Design

The graphical user interface (GUI) was designed keeping the PDA in mind. The user interface uses as many components that can be either easily clicked or tapped with a stylus. The following things were taken into consideration for the user interface design:

- A user would always want to have the list of peers and peer groups in front of him or her because of constant interaction with these entities.
- The limited screen size of the PDA requires that every function be provided without cluttering the screen. Thus every function is provided on a new screen.

Figure 13. Kiosk design for non-Jxta-enabled PDAs

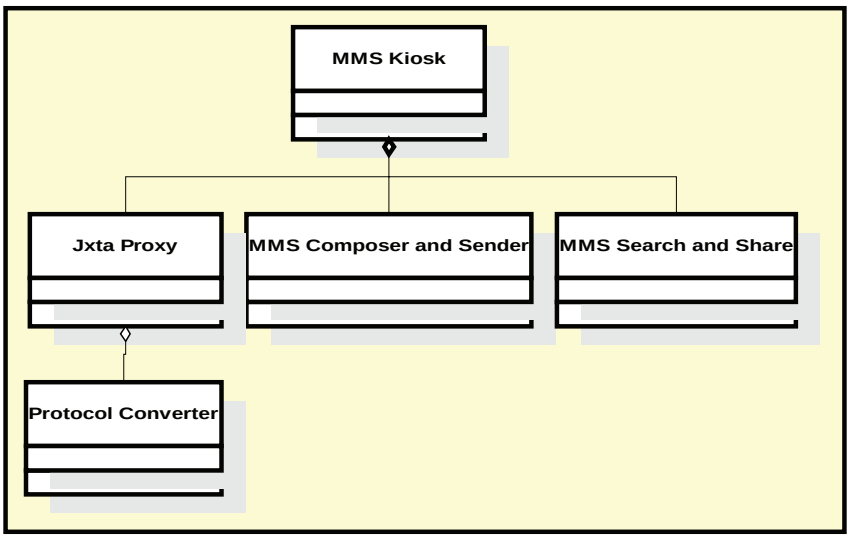

Figure 14. MMS player and sender

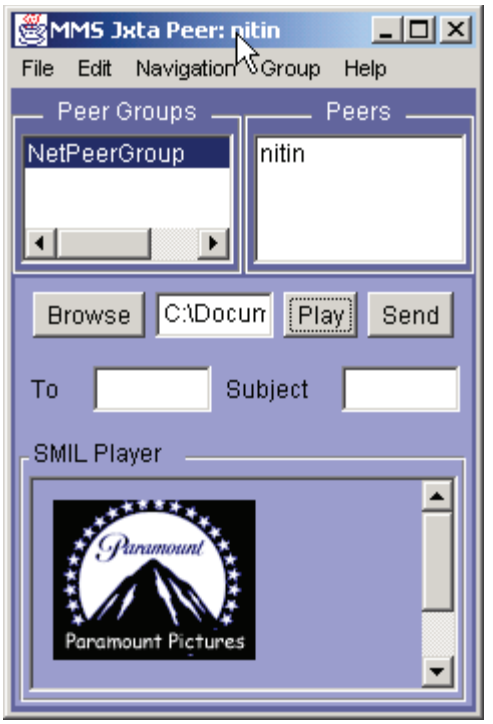

Figure 15. MMS search

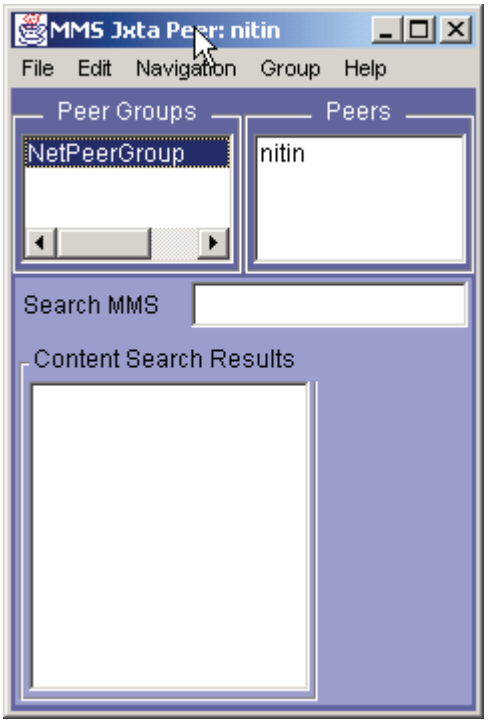

- This sort of layout would be ideal if service clients are to be loaded dynamically upon discovery of a service.

Figure 14 shows the MMS player and sender GUI. It also shows the lists of peer groups and peers currently visible. The peer groups and peers lists keep getting updated automatically. Figure 15 shows the MMS search GUI. A user can enter the keywords and press enter to search. A button will be added also to allow easy use on the PDA.

Figure 16 shows the MMS share GUI. It is similar to the MMS search GUI. It allows search for content in the current peer group. Figure 17 shows the MMS composer GUI. It is used to compose an MMS using various media files input by the user slide by slide. Figure 18 shows the Navigation menu, which is used to navigate to the various GUI components seen earlier. The design is such that the same region is used for the various functions. Figure 19 shows the Group menu that

Figure 16. MMS share

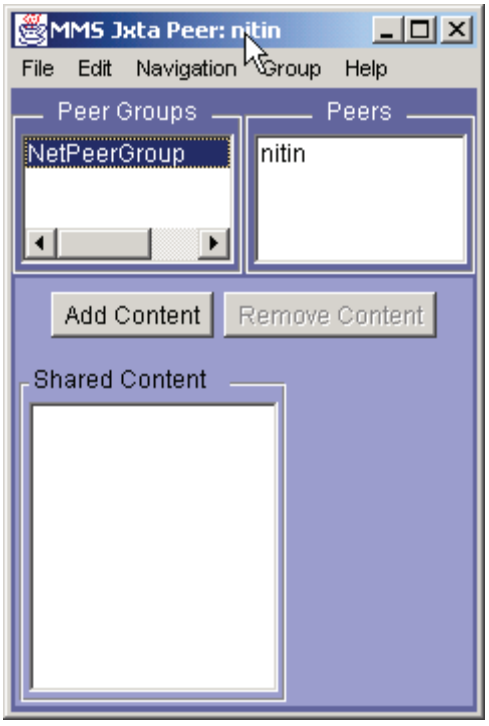

Figure 17. MMS composer

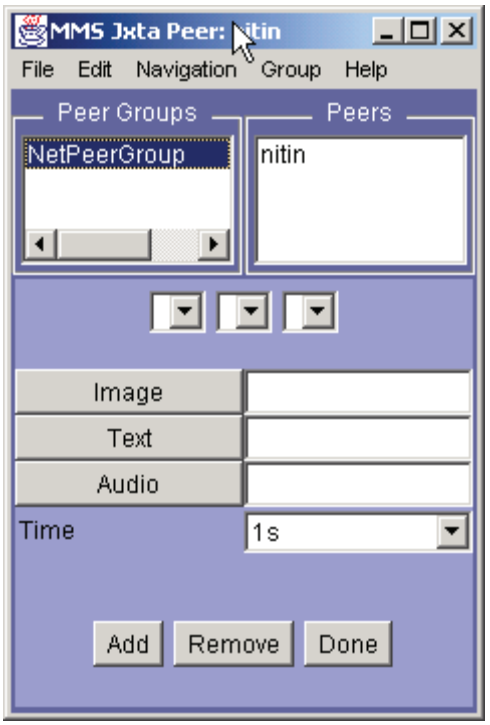

Figure 18. Navigation menu

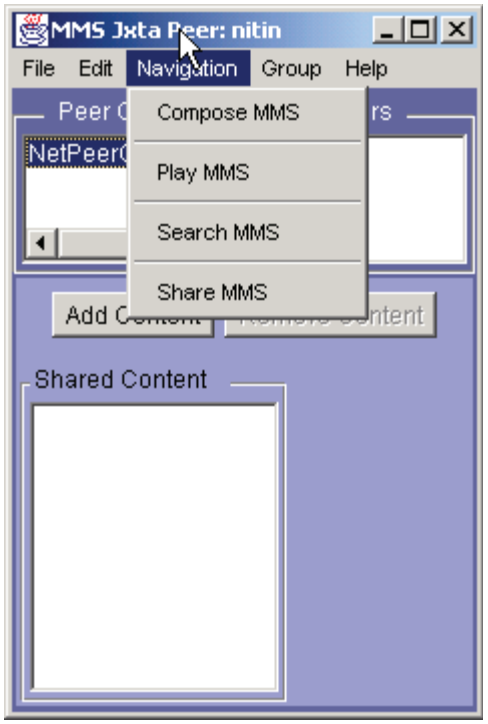

allows one to create, join, and leave a peer group after selecting in the peer group list below.

Comparison with Other MMS Solutions

There are some other MMS clients for the PDA that exist now. The one from Anny Way (MMS—Opportunities, migration and profits, 2003) is specifically for Pocket PC. EasyMessenger (EasyMessenger, 2003) from Oksijen Technologies is the only other Personal-Java-based MMS client but without the additional P2P features provided by us. Electric Pocket's Pixer (Pixer MMS, 2003) is another MMS client that only supports Pocket PC and Palm OS and can be used to send images only. There seems to be no work done on using MMS and Jxta together or for that matter not even EMS or SMS and Jxta.

All the solutions above are MMS clients with a view to sending multimedia messages, a progress from SMS or EMS. The MMS peer was developed with a view to making not only messaging a more pleasant and easier experience but also to provide features that would facilitate access to a variety of content. The searching and sharing of content from peers in the vicinity (shoppers) as well as content stores (kiosks) make it a compelling multimedia messaging solution.

FUTURE TRENDS

MMS Message Receiver Module for the PDA

The next step is to implement a receiver module for the PDA so that the MMS peer is able to achieve two-way messaging. In the following discussion we give a flowchart to decode the message if retrieved directly from the MMS proxy-relay using the HTTP GET method. This flowchart will be helpful for the implementation of the module to receive MMS messages on a PDA.

MMS Main Header Decoder

Figure 20 is a flowchart of the decoding process for the main header of the "m-retrieve-conf" (MMS client transaction specification, 2002) message of content type *application/vnd.wap.multipart.related*. It assumes that after the sending of the HTTP GET request, the MMS proxy-relay will return with a message along with the HTTP headers. The HTTP headers can be easily skipped by looking for two consecutive carriage returns and line feed pairs. After this the encoded MMS header starts which are read byte by byte till the byte of number of body parts is reached.

The "Read uintvar length" process needs some further explanation. Note that this value can be variable in length and uses the *variable length unsigned integer encoding* as discussed in the design and implementation section. A byte follows if the byte currently read has its most significant bit equal to 1. So one knows how many bytes to read without actually knowing the length of this value. Also note that the byte denoting number of body parts used after the main headers is going to be deprecated and might not be the perfect way to reach an end. This should not affect the decoding though, as the last decision box should be reached only after all the headers, their parameters, and their values have been read. This flowchart assumes no user-defined headers.

The To and Subject header values can have length bytes preceding the value. This length value could either be 1 byte or encoded using *variable length unsigned integer encoding.* Its length in the latter case is followed by the charset for the following text.

MMS Body Header Decoder

In Figure 21 "hLen" is the length of the whole header and "cLen" is the length of the Content Type header. Note that the Content Type header in the body part is just the value of this header and is not preceded by a code for the header name.

Service Client Plug-In Feature

The service client plug-in feature refers to the client download option. The current implementation assumes the client for a service to be there on the peer. As the peer already has core Jxta functionalities, it is a good idea to use them to provide this feature. The advertisements of a service could specify the location of a client, which could be transferred over to the peer and dynamically loaded. This is possible in Java using the API for loading classes. To enable this feature one could create a Jxta service that has clients registered with it.

PDA to PDA Messaging

With the existing application framework, PDA to PDA MMS messaging can be easily enabled using the Jxta messaging layer. As PDAs are more capable than mobile phones, even video could be enabled for PDA to PDA messaging. All it would mean is using another media type in the SMIL or the encoded message.

To account for different PDAs communicating, the user agent profile specification (UAProf; WAP UAProf, 2002) could be used for capability negotiation. The UAProf schema for MMS characteristics (client transactions) could be adapted to the PDA situation. The XML messaging layer for Jxta would enable the use of this XML scheme effectively.

CONCLUSION

The Jxta platform Personal Java port came out very recently and the application was designed and implemented with it in mind. If the basic platform functionalities have been ported correctly, then it should not take long to port this whole application to the PDA. The application conforms to the Personal Java standard when checked with the compliance tool. This implies it should work on the PDA without requiring any changes.

Figure 20. MMS main header decoder flowchart

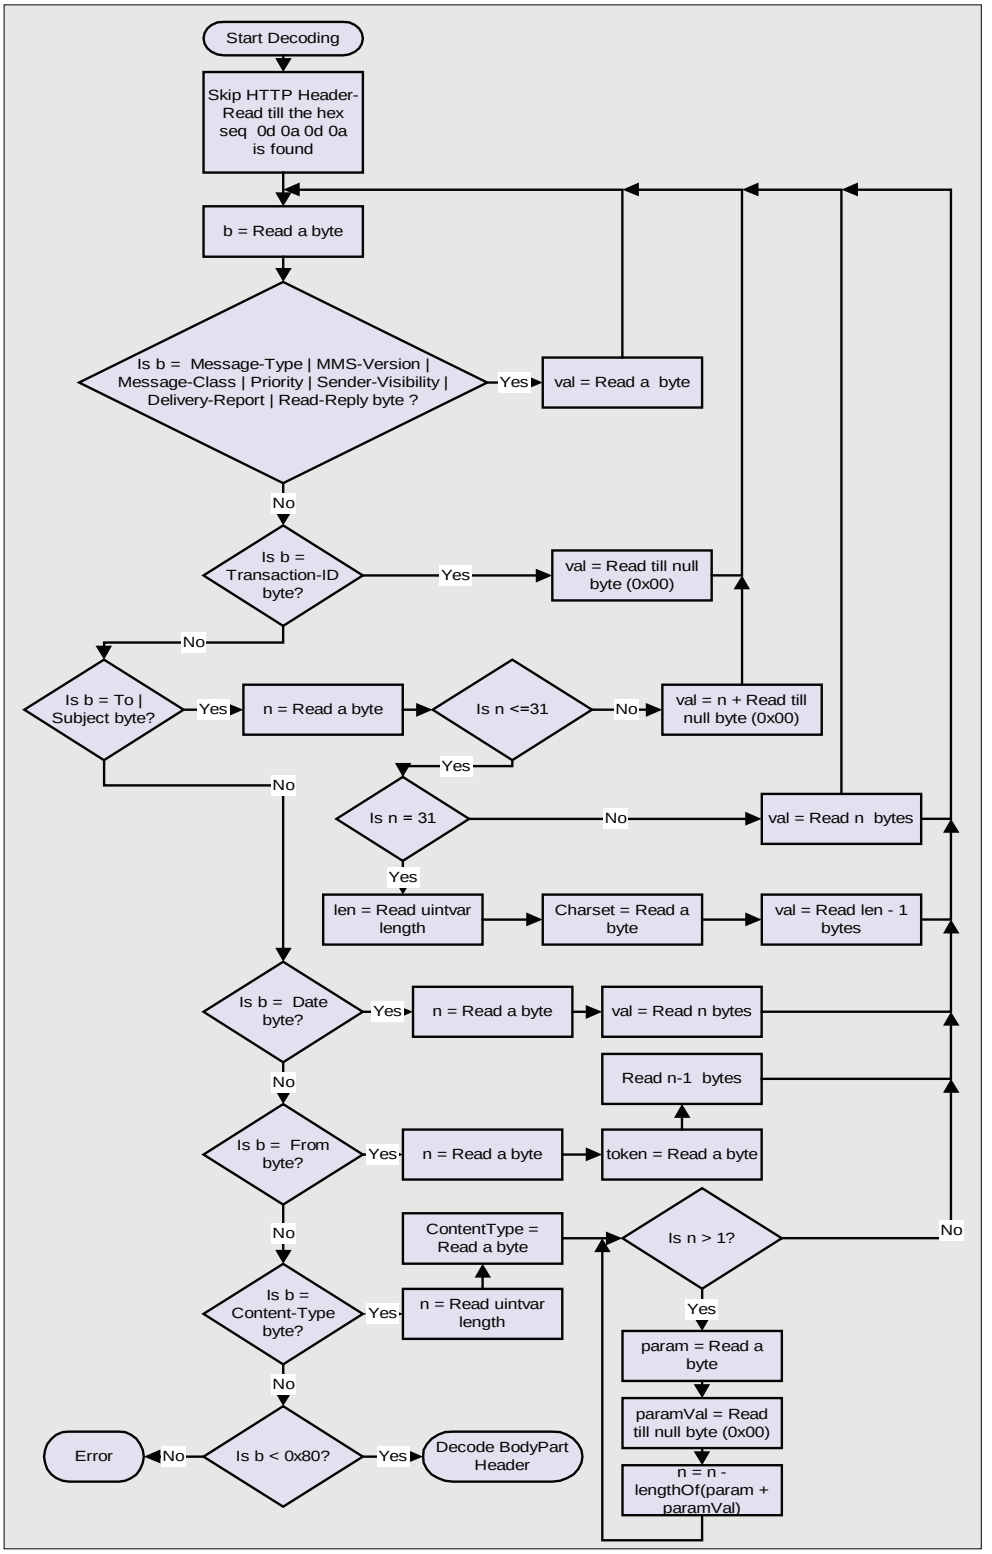

Figure 21. MMS body part header decoder flowchart

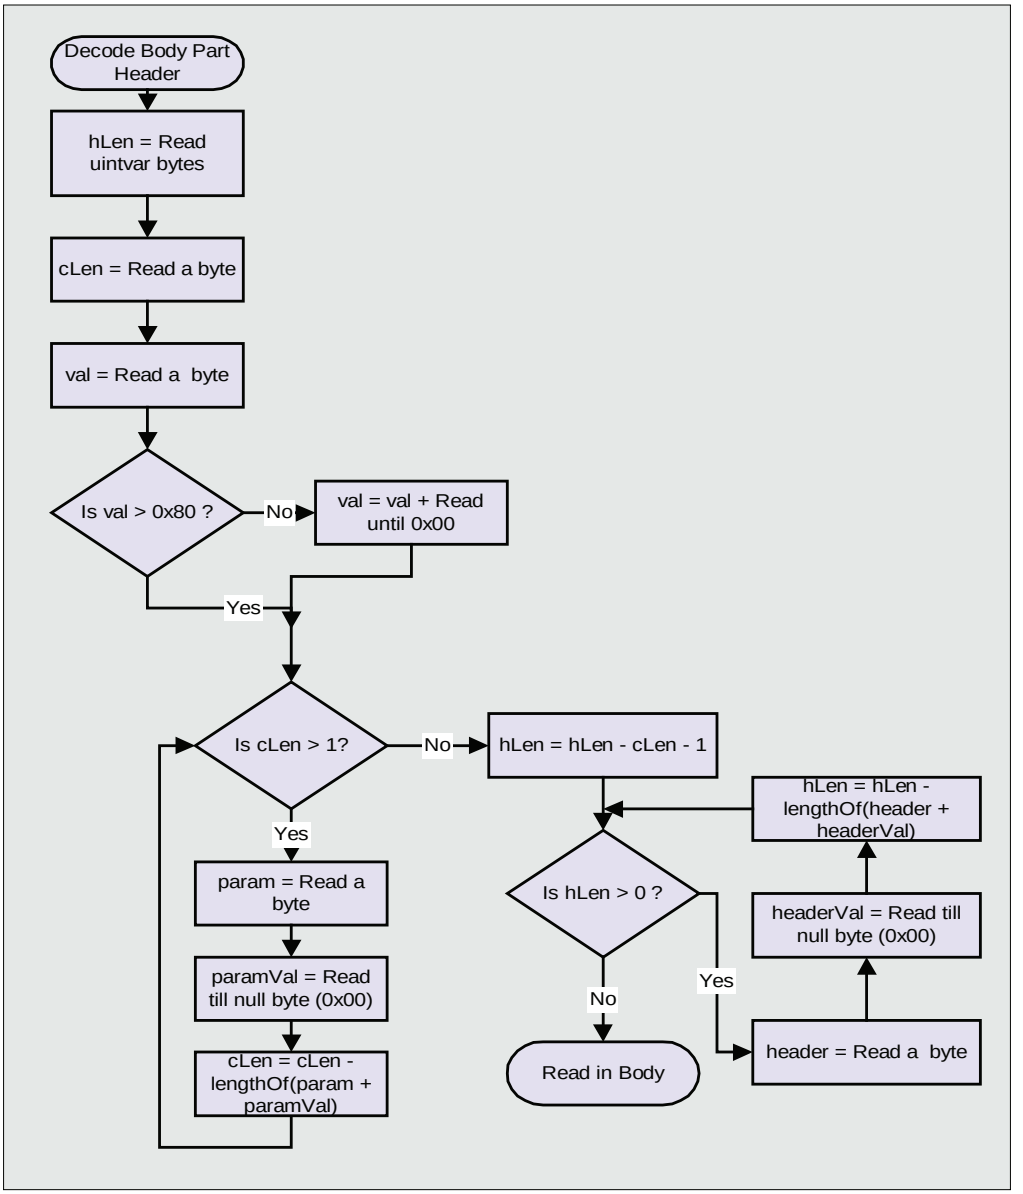

Currently the MMS client by itself works on the PDA. An MMS player and sharing of content were developed. The former was implemented while searching for a reasonably priced Bluetooth SDK for WinCE and trying various Bluetooth PCMCIA cards with the freely available Bluetooth stack called CStack (http://www.cstack.com).

The project will have a commercial value when shopping malls in Singapore install wireless networks or have wireless kiosks. This is the main driving force behind this project. Another driving force was to be able to pave a path to introduce multimedia messaging to students in Nanyang Technological University.

In conclusion, with the increase in memory and processing power of a plethora of mobile devices found in the market and the ongoing improvements in available bandwidth to the user, MMS

is a service to look forward to and more so with peer-to-peer technologies like Jxta, which will make it truly ubiquitous.

Chapter 1.13
Situated Multimedia for Mobile Communications

Jonna Häkkilä
Nokia Multimedia, Finland

Jani Mäntyjärvi
VTT Technical Centre of Finland, Finland

ABSTRACT

This chapter examines the integration of multimedia, mobile communication technology, and context-awareness for situated mobile multimedia. Situated mobile multimedia has been enabled by technological developments in recent years, including mobile phone integrated cameras, audio-video players, and multimedia editing tools, as well as improved sensing technologies and data transfer formats. It has potential for enhanced efficiency of the device usage, new applications, and mobile services related to creation, sharing, and storing of information. We introduce the background and the current status of the technology for the key elements constructing the situated mobile multimedia, and identify the existing development trends. Then, the future directions are examined by looking at the roadmaps and visions framed in the field.

INTRODUCTION

The rapid expansion of mobile phone usage during last decade has introduced **mobile communication** as an everyday concept in our lives. Conventionally, **mobile terminals** have been used primarily for calling and employing the short message service (SMS), the so-called text messaging. During recent years, the multimedia messaging service (MMS) has been introduced to a wide audience, and more and more mobile terminals have an integrated camera capable of still, and often also video recording. In addition to imaging functions, audio features have been added and many mobile terminals now employ (e.g., an audio recorder and an MP3 player). Thus, the capabilities of creating, sharing, and consuming multimedia items are growing, both in the sense of integrating more advanced technology and reaching ever-increasing user groups. The

introduction of third generation networks, starting from Japan in October 2001 (Tachikawa, 2003), has put more emphasis on developing services requiring faster data transfer, such as streaming audio-video content, and it can be anticipated that the role of multimedia will grow stronger in mobile communications.

The mobile communications technology integrating the **multimedia** capabilities is thus expected to expand, and with this trend both the demand and supply of more specific features and characteristics will follow. In this chapter we concentrate on describing a specific phenomenon under the topic of mobile multimedia—namely, integrating **context awareness** into mobile multimedia.

Context-awareness implies that the device is to some extent aware of the characteristics of the concurrent usage situation. Contextual information sources can be, for instance, characteristics of the physical environment, such as temperature or noise level, user's goals and tasks, or the surrounding infrastructure. This information can be bound to the use of mobile multimedia to expand its possibilities and to enhance the **human computer interaction**. Features enhancing context awareness include such things as the use of context-triggered device actions, delivery of multimedia-based services, exploiting recorded metadata, and so on.

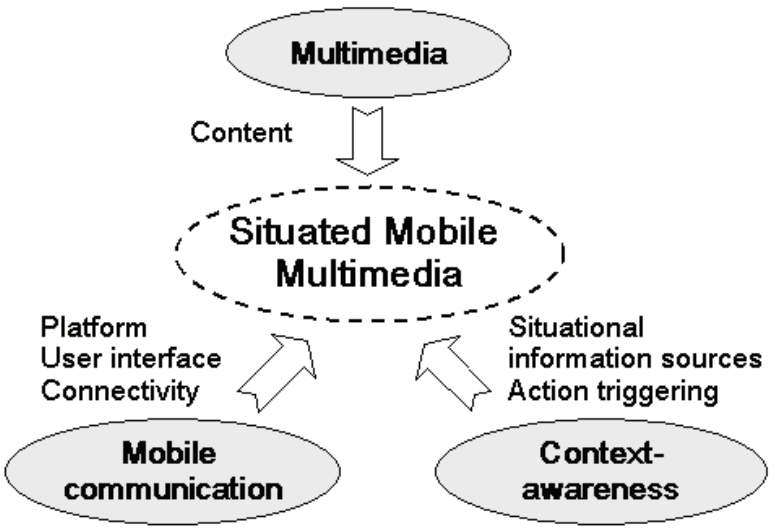
In this chapter we will look into three key aspects—mobile communications, multimedia, and context-awareness—and consider how they can be integrated. We will first look at each key element to understand the background and its current status, including identifying the current development trends. Then the future directions will be examined by looking at the roadmaps and visions framed in the field. The challenges and possibilities will then be summarized.

BACKGROUND

The development of digital multimedia has emerged in all segments of our everyday life. The home domain is typically equipped with affiliated gadgets, including digital TV, DVD, home theaters, and other popular infotainment systems. The content of the digital multimedia varies from entertainment to documentation and educative material, and to users' self-created documents. Learning tools exploiting digital multimedia are evident from kindergarten to universities, including all fields of education (e.g., language learning, mathematics, and history). Digital multimedia tools are used in health care or security monitoring systems. So far, the platforms and environments for the use of digital multimedia have been non-mobile, even "furniture type" systems (i.e., PC-centered or built around a home entertainment unit). The PC, together with the Internet, has been the key element for storing, editing, and sharing multimedia content. User-created documents have involved gadgets such as video cameras or digital cameras, from where the data needs to be transferred to other equipment to enable monitoring or editing of the produced material.

However, the role of mobile multimedia is becoming increasingly important both in the sense of creating, and sharing and monitoring the content. The increased flexibility of use following from the characteristics of a mobile communication device—it is a mobile, personal, and small-size gadget always with the user—has expanded the usage situations and created possibilities for new applications; the connection to the communication infrastructure enables effective data delivery and sharing. Adding the situational aspect to mobile multimedia can be utilized using context awareness, which brings information of the current usage situation or preferred functions, and can be used for action triggering for instance (Figure 1). Here, the multimedia content is dealt with in

Figure 1. Integrating multimedia, mobile communication technology, and context awareness



a mobile communication device, most often a mobile phone, which offers the physical platform and user interface (UI) for storing, editing, and observing the content.

In the following sections, we first look at the use of mobile communication technology and then the concept of context awareness more closely.

Mobile Phone Culture

During recent decades, mobile communication has grown rapidly to cover every consumer sector so that the penetration rates approach and even exceed 100% in many countries. Although the early mobile phone models were designed for the most basic function, calling, they soon started to host more features, first related primarily to interpersonal communication, such as phone-book and messaging applications accompanied by features familiar to many users from the PC world (e.g., electronic calendar applications and text document creation and editing). These were followed by multimedia-related features, such as integrated cameras, FM radios, and MP3 players, and applications for creating, storing, and sharing multimedia items.

Defining different audio alert profiles and ringing tones, and defining distinct settings for different people or caller groups, expanded the user's control over the device. Personalization of the mobile phone became a strong trend supported by changeable covers, operator logos, and display wallpapers. All this emphasized the mobile phone as a personal device.

The text messaging culture was quickly adopted by mobile phone users, especially by teenagers. The asynchronous communication enabled new styles of interaction and changed the way of communicating. Text messaging has been investigated both from the viewpoint of how it is associated with everyday life situations, the content and character of messaging, and the expression and style employed in messaging (Grinter & Eldridge, 2003). When looking at teenagers' messaging behavior, Grinter and Eldridge (2003) report on three types of messaging categories: chatting, planning activities, and coordinating communications in which the messaging leads to the use of some other communication media, such as face-to-face meetings or phone calls. Text messaging has also created its own forms of expression (e.g., the use of shortened words,

mixing letters, and number characters, and the use of acronyms that are understood by other heavy SMS users or a certain group).

Due to the novelty of the topic, mobile communication exploiting multimedia content has so far only been slightly researched. Cole and Stanton (2003) report that mobile technology capable of pictorial information exchange has been found to hold potential for a youngster's collaboration during activities, for instance, in story telling and adventure gaming. Kurvinen (2003) reports a case study on group communication, where users interact with MMS and picture exchange for sending congratulations and humorous teasing. Multimedia messaging has been used, for example, as a learning tool within a university student mentoring program, where the mentors and mentees were provided with camera phones and could share pictorial information on each other's activities during the mobile mentoring period (Häkkilä, Beekhuyzen, & von Hellens, 2004). In a study on camera phone use, Kindberg, Spasojevic, Fleck, and Sellen (2005) report on user behavior in capturing and sharing the images, describing the affective and functional reasons when capturing the photos, and that by far the majority of the photos stored in mobile phones were taken by the user him or herself and kept for a sentimental reason.

Context Awareness for Mobile Devices

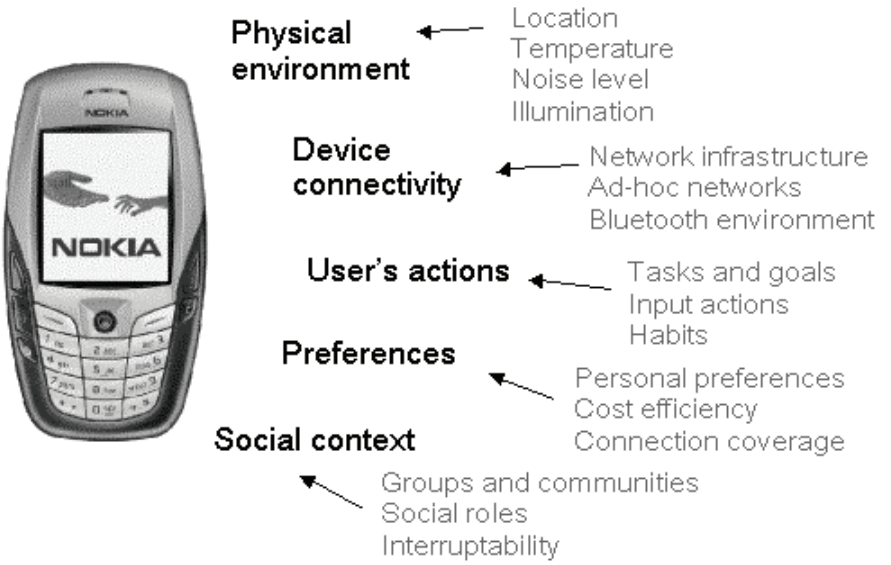
In short, context awareness aims at using the information of the usage context for better adapting the behavior of the device to the situation. Mobile handsets have limited input and output functionalities, and, due mobility, they are used in altering and dynamically varying environments. Mobile phones are treated as personal devices, and thus have the potential to learn and adapt to the user's habits and preferences. Taking these special characteristics of mobile handheld devices into account, they form a very suitable platform for context-aware application development. Context awareness has been proposed as a potential step in future technology development, as it offers the possibilities of smart environments, adaptive UI's, and more flexible use of devices.

When compared with the early mobile phone models of the 1990s, the complexity of the device has increased dramatically. The current models have a multiple number of applications, which, typically, must still be operated with the same number of input keys and almost the same size display. The navigation paths and the number of input events have grown, and completing many actions takes a relatively long time, as it typically requires numerous key presses. One motivation for integrating context awareness into mobile terminals is to offer shortcuts to the applications needed in a certain situation, or automating the execution of appropriate actions.

The research so far has proposed several classifications for contextual information sources. For example, the TEA (Technology for Enabling Awareness) project used two general categories for structuring the concept of context: human factors and physical environment. Each of these has three subcategories: human factors divides into information on the user, his or her social environment, and tasks, and physical environment distinguishes location, infrastructure, and physical conditions. In addition, orthogonal to these categories, history provides the information on the changes of context attributes over time Schmidt, Beigl, and Gellersen (1999). Schilit, Adams, and Want (1994) propose three general categories: user context, physical context, and computing context. Dey and Abowd (2000) define the context as "any information that can be used to characterize the situation of an entity."

In Figure 2, we present the contextual information sources as they appear from the mobile communication viewpoint, separating the five different main categories—physical environment, device connectivity, user's actions, preferences, and social context—which emphasize the spe-

Figure 2. Context-aware mobile device information source categories and examples



cial characteristics of the field. These categories were selected as we saw them to represent the different aspects especially important to the mobile communication domain, and they are briefly explained in the following. The proposed categories overlap somewhat and individual issues often have an effect on several others. Thus, they are not meant as strictly separate matters but aim to construct an entity of overall contextual information sources.

Physical environment is probably the most used contextual information source, where the data can be derived from sensor-based measurements. Typical sensor data used in context-aware research includes temperature, noise, and light intensity sensors and accelerometers. Location, a single attribute that has resulted in the most research and applications in the field of mobile context-aware research, can be determined with GPS or by using the cell-ID information of the mobile phone network. *Device connectivity* refers to the information that can be retrieved via data transfer channels that connect the device to the outside world, other devices, or the network infrastructure. This means not only the mobile phone network, such as GSM, TDMA, or GPRS connections, but also ad hoc type networks and local connectivity systems, such as Bluetooth environment or data transfer over infrared. A certain connectivity channel may enable different types of context-aware applications: for example, Bluetooth can be used as a presence information source due its short range. The category *user's actions* implies the user's behavior, which here covers a wide range of different aspects from single input events, such as key presses and navigation in the menus, to prevailing tasks and goals, and general habits typical of the individual user.

Contrary to the previous categories, which are more or less typical of the research in the field of context awareness, we propose that the last two categories have an important role when using a mobile communication device. By *preferences* and *social context*, we refer to the factors relating to the use situations especially important from the end-user perspective. The preferences cover such issues as cost-efficiency, data connection speed, and reliability, which are important to the end-user and which relate closely to the connectivity issues dealing with handovers and alternative data

transfer mediums. But, not only technical issues affect the usage. The user's personal preferences, which can offer useful information for profiling or personalizing mobile services, are also important. *Social context* forms an important information category as mobile terminals are still primarily used for personal communication and are often used in situations where the presence of other people cannot be avoided. This category forms a somewhat special case among the five classes (Figure 2) as it has a strong role both as an input and an output element of a context-aware application, so it can—and should—be taken into account both as an information source and in the consequent behavior of a context-aware system. By inferring the prevailing social context, one can not only gain information on the preferred functions but also vice versa–the social context also has an effect on how we wish the device to react in terms of interruptability or privacy.

Contextual information can be used for automating certain device actions: when specified conditions are fulfilled, the detected context information triggers a pre-defined action to take place. As an example, a mobile phone ringing tone volume could be automatically set to maximum if the surrounding noise exceeded 90 dB. In addition to automated device behavior, semi-automated and manual execution of actions has been suggested to ensure an appropriate level of user control (Mäntyjärvi, Tuomela, Känsälä, & Häkkilä, 2003). Previous work in the field of mobile context-aware devices has implemented location-aware tour guides and reminders (Davies, Cheverst, Mitchell, & Efrat, 2001), where accessing a certain location triggers the related information or reminder alert to appear on the device screen, or the automated ringing tone profile changes (Mantyjärvi & Seppänen, 2003), as does screen layout adaptation (Mäntyjärvi & Seppänen, 2003) in certain environmental circumstances.

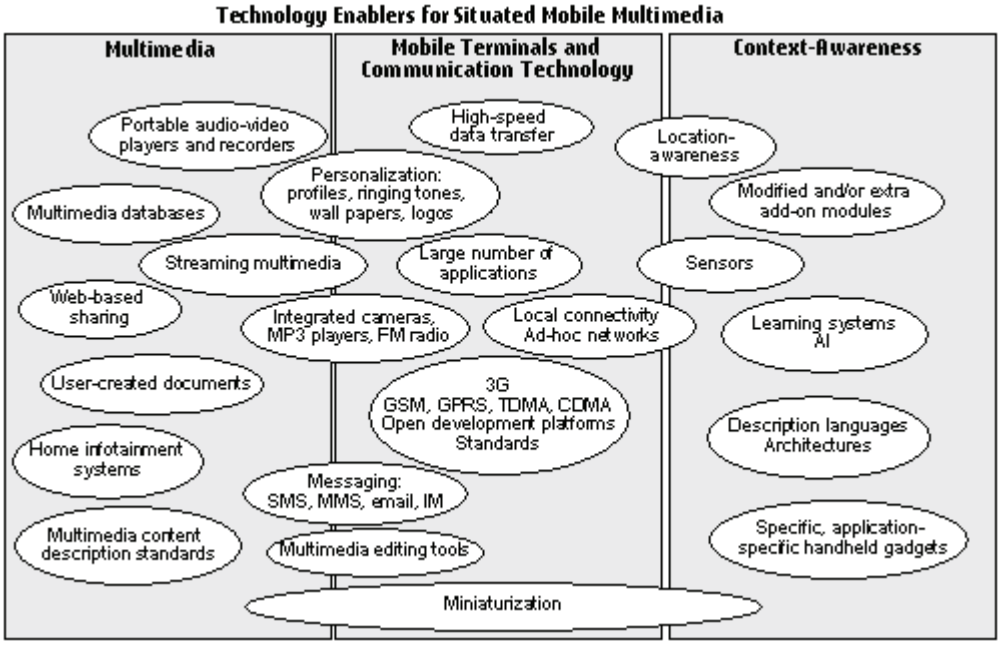
CURRENT STATUS

Technology Enablers

With the term "technology enabler," we mean the state-of-the-art technology that is mature enough and commonly available for building systems and applications based on it. When looking at the current status of the technology enablers for situated multimedia (Figure 3) it can be seen that there are several quite different factors related to the three domains of multimedia, mobile technology and context awareness that are still quite separated from each other. Recent developments have brought mobile technology and multimedia closer to each other, integrating them into mobile phone personalization, multimedia messaging, and imaging applications. Context awareness and mobile communication technology have moved closer to each other mainly on the hardware frontier, as GPS modules and integrated light-intensity sensors and accelerometers have been introduced for a number of mobile phones. Altogether, one can say that the areas presented in Figure 3 are under intensive development, and the features are overlapping more and more across the different domains. The development in hardware miniaturization, high-speed data transfer, data packaging, artificial intelligence, description languages, and standardization are all trends that lead toward seamless integration of the technology with versatile and robust applications, devices, and infrastructures.

A closer look at the current status of context awareness shows that the applications are typically built on specific gadgets, which include such device-specific features as modified hardware. However, the development is toward implementing the features on commonly used gadgets, such as off-the-self mobile phones or PDA's, so that platform-independent use of applications and services is possible. Also, applications utilizing location-awareness have typically concentrated on a defined, preset environment, where the beacons

Figure 3. Technology enablers and their current status for situated mobile multimedia



for location-detection have been placed across a limited, predefined environment, such as a university campus, distinct building, or certain area of the city. Thus, the infrastructure has not yet been generally utilized, and expanding it would require an extra effort. So far, the accuracy of GPS or cellular-ID-based recognition has often been too poor for experimenting with location-sensitive device features or applications requiring high location detection resolution. In mobile computing, it is challenging to capture a context, as a description of a current (e.g., physical situation) with a full confidence (==1). Various machine intelligence and data analysis-based methods such as self organizing neural networks (Flanagan, Mäntyjärvi, & Himberg, 2002), Bayesian approach (Korpipää, Koskinen, Peltola, Mäkelä, & Seppänen, 2003), fuzzy reasoning (Mäntyjärvi & Seppänen, 2003), and hidden Markov models (Brand, Oliver, & Pentland, 1997), to mention a few, have been studied to. In most approaches, quite good context recognition accuracies (~70-100%) are presented. However, it must be noted that all results are obtained with different and relatively limited data sets and results are quite subjective. The mobile context aware computing research, particularly context recognition, still lacks the systematic approach (e.g., benchmark datasets).

When examining the current technological status in mobile multimedia, the strongest trend during recent years has been the introduction of the multimedia messaging service (MMS), which has now established its status as an "everyday technology" with widespread use of so-called smart phones and camera phones. In Europe, it is estimated that people sent approximately 1.34 billion multimedia messages in 2005. This shows that MMS is a considerable potential technology that end users have become to adopt, although this is only a small fraction of the number of SMSs sent, which has been estimated to be 134,39 billion in 2005 (Cremers & de Lussanet, 2005).

Personalization of mobile phones, which so far has been executed manually by the user, has taken the form of changing ringing tones, operator

logos, and wallpapers. Multimedia offers further possibilities for enhancing the personalization of the mobile device — both from the user's self-expression point of view when creating his or her own items and as the receiving party when the user may access multimedia content via peer-to-peer sharing, information delivery, or mobile services.

Toward Situated Mobile Multimedia

The research in the area of situated mobile multimedia is still in its early development stage and many of the current projects are very limited, still concentrating mainly on textual information exchange. The most common contextual information source used in mobile communication is the location. In addition to the information bound to the physical location, information on the current physical location and distance may provide useful data for (e.g., time management and social navigation). E-graffiti introduces an on-campus location-aware messaging application where users can create and access location-associated notes, and where the system employs laptop computers and wireless network-based location detection (Burrell & Gay, 2002). InfoRadar supports public and group messaging as a PDA application, where the user interface displays location-based messages in a radar-type view showing their orientation and distance from the user (Rantanen, Rantanen, Oulasvirta, Blom, Tiitta, & Mäntylä, 2004). The applications exploiting multimedia elements are typically location-based museum or city tour guides for tourists (see e.g., Davies & al., 2001).

Multimedia messaging has become a popular technique for experimentation within the field since there is no need to set up any specific infrastructure and standard mobile phones can be used as the platform. The widespread use of mobile phones also enables extending the experiments to large audiences, as no specific gadgets need to be distributed. These aspects are used in the work of Koch and Sonenberg (2004) for developing an MMS-based location-sensitive museum information application utilizing Bluetooth as the sensing technology. In the Rotuaari project carried out in Oulu, Finland, location-aware information and advertisements were delivered to mobile phones in the city center area by using different messaging applications, including MMS ("Rotuaari," n.d.).

Use of context can be divided into two main categories: push and pull. In the push type of use, the context information is used for automatically sending a message to the user when he or she arrives at a certain area, whereas with the pull type, the user takes the initiative by requesting context-based information, such as recommended restaurants in the prevailing area.

Currently, most of the experiments concentrate on the push type of service behavior. This is partially due to the lack of general services and databases, which, in practice, prevents the use of the request-based approach. A general problem is the shortage of infrastructure supporting sensing, and the absence of commonly agreed principles for service development. Attempts to develop a common framework to enable cross-platform application development and seamless interoperability exist, but so far there is no commonly agreed ontology or standard.

In Häkkilä and Mäntyjärvi (2005) we have presented a model for situated multimedia and how context-sensitive mobile multimedia services could be set, stored, and received, and examined users' experiences on situated multimedia messaging. The model combines multimedia messaging with the context awareness of a mobile phone and phone applications categorized into three main groups, notification, reminder, and presence, which were seen to form a representative group of applications relevant to a mobile handset user. The composing entity (i.e., a person or a service) combines the device application information, the multimedia document, and the context information used for determining the message delivery

conditions to a situated multimedia message. After sending, the message goes through a server containing the storage and context inferring logic. The server delivers the message to the receiving device, where it has to pass a filter before the user is notified of the received message. The filter component prevents the user from so-called spam messages and enables personalized interest profiles.

FUTURE TRENDS

In order to successfully bring new technology to the use of a wide audience, several conditions must be fulfilled. As discussed before, the technology must be mature enough so that durable and robust solutions can be provided at a reasonable price, and an infrastructure must be ready to support the features introduced. The proposed technological solutions must meet the end users' needs, and the application design has to come up with usable and intuitive user interfaces in order to deliver the benefits to the users. Importantly, usable development environments for developers must exist. Usability is a key element for positive user experience. In the ISO 13407 (3.3), standard on human-centred design processes for interactive systems, usability has been defined to be the "extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" (Standard ISO 13407, 1999).

In this section, we discuss the near and medium-term future concepts focusing on situated mobile multimedia enabled by the development trends in context awareness, multimedia technologies, and mobile terminals.

Context Awareness

Context awareness has been recognized as one of the important technology strategies on the EC level (ITEA, 2004). The key factors for the human-system interaction of mobile devices recognized by ITEA are: simple, self-explanatory, easy to use, intelligent, context-aware, adaptive, seamless, and interoperable behaviour of user interfaces. The main driving forces for the development of context-awareness for mobile devices are that the user interface of mobile terminals is limited (by the small physical size), and there is an enormous expected growth in mobile applications and services to be accessed by terminals in near future. So, it can be said that the need for context-awareness is evident and the need is strongly market and industry-driven. The main enablers for the context-awareness of mobile devices are: ease of use and an open development environment for smart phones, architectures for mobile context-awareness enabling advanced context reasoning, miniaturized and low-power sensing technologies and data processing, and suitable languages for flexibly describing the context information. These main enablers are recognized in the research field and the research is rapidly advancing globally toward true context-awareness.

However, promising technological solutions often have some drawbacks. In context awareness, they are related to user experience. While the nice scenarios of context awareness provide a better tomorrow via intelligently behaving user interfaces—the right information in the right situation—the reality might be a bit different. For example, entering a new context may cause the adapted UI to differ radically from what it was a moment ago, and a user may find him or herself lost in the UI. On the other hand, the device may incorrectly recognize the situation and behave in an unsuitable manner. These are just examples of horror usability scenarios, but the idea is that the responsibility for the functionality of the device is taken away from the user, and when a user's experience of a product is negative, the consequences for the terminal business may be fatal.

There are ways to overcome this problem. One—and a careful—step toward successful context-awareness for mobile terminals is to

equip the devices with all the capabilities for full context-awareness and provide an application, a tool by which a user him or herself may configure a device to operate in a context-aware manner (Mäntyjärvi et al., 2003). Obviously, this is an opportunity to accomplish context-aware behavior, but on the other hand, the approach sets more stress on the user when he or she must act as an engineer (so-called end user programming), and continuous configuration may become a nuisance. However, this approach is more attractive for the terminal business when the user him or herself is responsible for any possible unwanted behavior of a device instead of the device manufacturers.

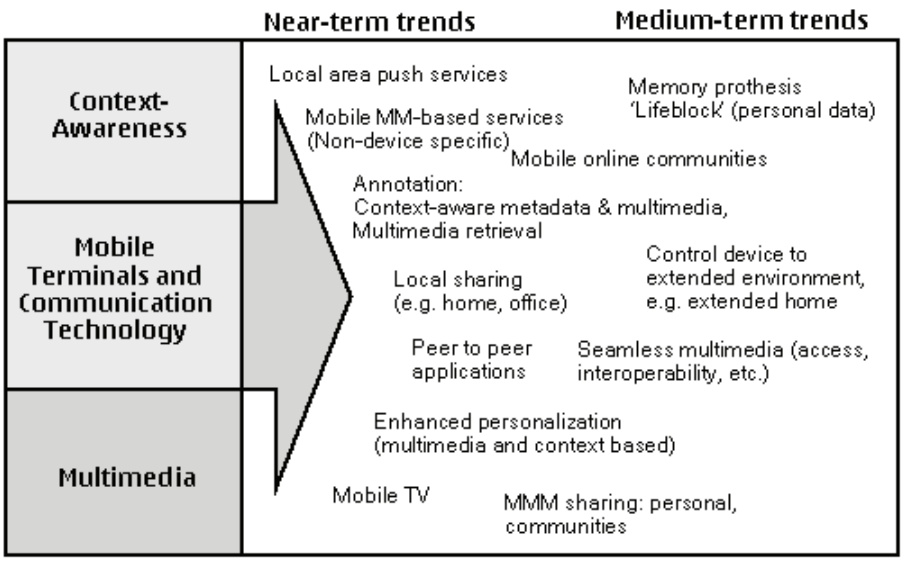
Future Development Trends

In the very near future, we are to witness a growth in basic wireless multimedia applications and services (Figure 4). By basic services and applications we refer to local services (push multimedia kiosks, mobile mm content, etc) and mobile multimedia services, including downloadable content: ringtones, videos, skins, games, and mobile terminal TV. Streaming multimedia is strongly emerging, and mobile TV in particular has raised expectations as the next expanding application area. At the moment, several broadcasting standards are dominating the development in different parts of the world: ISDB-T in Japan; DVB-H, particularly in Europe and the US; and DBM, especially in Korea, where several mobile terminals on the market already support it. Although the status of mobile TV is not reaching a wide audience of end users yet, a number of trials are in existence, such as a half-year trial in Oxford (UK) with NTL Broadcast and O2 starting in the summer of 2005, when 350 users will access several TV channels with the Nokia 7710 handset (BBC News, 2005).

The increased growth in MM services is supported by the maturation of various technologies, including 3G-networks, extensive content communication standards such as MPEG 7, multimedia players and multimedia editing tools for mobile terminals. In addition, an increase in the amount of mobile multimedia is expected to support the stimulation of the mobile service business.

The increase in the amount of personal multimedia is expected to be considerable, mainly

Figure 4. Future development trends enabled by context-awareness, mobile terminals, and communications technology and multimedia



because of digital cameras and camera phones. The explosion of mobile personal multimedia has already created an evident need for physically storing data—by which we mean forms of memory: memory sticks and cards, hard-drive discs, etc.

However, another evident need is end user tools and software for managing multimedia content—digital multimedia albums, which are already appearing in the market in the form of home multimedia servers enabling communication of multimedia wirelessly locally at home, and personal mobile terminal MM album applications.

The next overlapping step in the chain of development is the mobile online sharing of the multimedia content of personal albums. People have always had a need to get together (i.e., the need to form communities) (e.g., around hobbies, families, work, etc). Today, these communities are in the Web and the interaction is globally online. Tomorrow, the communities will be mobile online communities that collaborate and share multimedia content online.

In the near future, as the personal multimedia content is generated with context-aware mobile phones, the content will be enhanced semantic context-based annotations, with time, place, and social and physical situation. The created metadata will be sketched with effective description languages enabling more effective information retrieval in the mobile semantic web and more easily accessible and easy to use multimedia databases.

Even though we have only identified a few near-term concepts enabled by the combination of context awareness and mobile multimedia technologies, we can also see the effects in the long term. The role of the mobile terminal in creating, editing, controlling, and accessing personal and shared multimedia will emphasize. The emerging standards in communication and in describing content and metadata enable seamless access and interoperability between multimedia albums in various types of systems. The personal "My Life" albums describing the entire life of a person in a semantically annotated form are become commonplace.

CONCLUSION

In this chapter we have examined the concept of situated mobile multimedia for mobile communications. We have introduced the characteristics of the key elements — multimedia, context awareness, and mobile communications — and discussed their current status and future trends in relation to the topic. Linked to this, we have presented a new categorization for contextual information sources, taking account of the special characteristics of mobile communication devices and their usage (Figure 2).

Integrating context awareness into mobile terminals has been introduced as a potential future technology in several forums. The motivation for this arises from the mobility characteristics of the device, its limited input and output functionalities, and the fact that the complexity of the device and its user interface is constantly growing. Context awareness as such has potential to functions such as automated or semi-automated action executions, creating shortcuts to applications and device functions, and situation-dependent information and service delivery. In this chapter we have limited our interest to examining the possibilities of combining the multimedia content to the phenomenon.

Currently, most of the mobile devices employing context awareness are specifically designed for the purpose, being somehow modified from the standard products by adding sensor modules. The lack of commonly agreed ontologies, standards, and description languages, as well as the shortage of suitable, commonly used gadgets as application platforms, has hindered the development of generally available, wide-audience services, and applications.

Multimedia, especially in the form of camera phones and Multimedia Messaging Service, has become a solid part of mobile communication technology during recent years. MMS enables easy delivery of multimedia content to a broad audience in a personalized manner. With situated multimedia, this means information delivery with multimedia content, such as information on local services or current events. Context awareness can also be exploited for executing underlying actions hidden from the user, such as selecting the data transfer medium for lower-cost streaming or better connection coverage.

KEY TERMS

Camera Phone: Mobile phone employing an integrated digital camera.

Context Awareness: Characteristic of a device that is, to some extend, aware of its surroundings and the usage situations

Location Awareness: Characteristic of a device that is aware of its current location.

Multimedia Messaging Service (MMS): Mobile communication standard for exchanging text, graphical, and audio-video material. The feature is commonly included in so-called camera phones.

Situated Mobile Multimedia: Technology feature integrating mobile technologies, multimedia, and context awareness.

This work was previously published in Handbook of Research on Mobile Multimedia, edited by I. K. Ibrahim, pp. 326-339, copyright 2006 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 1.14
Current Status of Mobile Wireless Technology and Digital Multimedia Broadcasting*

Soldier Design LLC, USA

ABSTRACT

The purpose of this chapter is to present an overview of wireless mobile technology, its applications, with a focus on digital multimedia broadcasting (DMB) technology. The chapter also explores the research methodology regarding users' perception on DMB cellular phones and presents empirical findings. Implications for future research are presented. The report attempts to provide stimulating answers by investigating the following questions: (1) Do users perceive easy access to DMB applications as a satisfactory service offered by DMB service providers? (2) Do users perceive high-quality DMB program content as a satisfactory service offered by the DMB service providers? (3) Are there differences between different age groups in terms of their perception of DMB phone prices, phone usage time, program content, and services?

INTRODUCTION

Wireless mobile technology and handheld devices are dramatically changing the degrees of interaction throughout the world, further creating a ubiquitous network society. The emergence of these wireless devices has increased accuracy, ease-of-use, and access rate, all of which is increasingly essential as the volume of information handled by users expands at an accelerated pace.

Mobile TV broadcasting technology, as a nascent industry, has been paving a new way to create an intersection of telecommunication and media industries, all of which offers new opportunities to device makers, content producers, and mobile network operators.

There are currently various wireless connectivity standards (e.g., Wi-Fi, Bluetooth, Radio Frequency Identification [RFID], etc.), which have been expanding across all vertical industries, in an era of mobile and ubiquitous computing, which provides access to anything, anytime, and anywhere. Mobile TV technologies have been creating a buzz, as it adds a new dimension to the "on the go" mobility factor—simultaneous audio and video services are broadcasted in real-time to mobile devices in motion, such as mobile TV-enabled phones, PDAs, and car receivers.

There are currently three major competing standards: digital video broadcasting for handhelds (DVB-H), which is going through trial phases in Europe; digital multimedia broadcasting (DMB), which has been adopted in South Korea and Japan; and MediaFLO (QUALCOMM Inc., 2005), which is currently in trial phase in the United States with plans to launch by late 2007. The competition scheme is further intensified given the challenge of how quickly terrestrial and satellite DMB can be deployed and commercialized throughout countries such as Korea, Japan, and Europe. Additionally, there is pressure to recoup the costs with creating the network and catapult the technology to the ranks of industry standard.

The purpose of this chapter is to present an overview of wireless mobile technology, its applications, with a focus on DMB technology. The chapter also explores the research methodology regarding users' perception on DMB cellular phones and presents empirical findings from Study Phases I and II, along with actual DMB subscriber usage results. Implications for future research are presented.

Given that the research topic of DMB has not yet been covered extensively, the use of qualitative methods is considered advantageous when exploring the topic to develop theoretical variables, which may then be employed in quantitative research. Thus, with the difference found between the DMB cellular phone usage experience and traditional cellular phone usage, qualitative methodology was applied to Study Phase I. The project was then triangulated by the use of quantitative methodology in Study Phase II to develop an additional understanding of the DMB cellular phone users' experiences as identified in Study Phase I.

The report attempts to provide stimulating answers by investigating the following questions: (1) Do users perceive easy access to DMB applications as a satisfactory service offered by DMB service providers? (2) Do users perceive high-quality DMB program contents as a satisfactory service offered by the DMB service providers? (3) Are there differences between different age groups in terms of their perception of DMB phone prices, phone usage time, program contents, and services?

WIRELESS MOBILE TECHNOLOGIES: CURRENT STATUS AND CONCEPTS

Over the last decade, wireless technologies have attracted unprecedented attention from wireless service providers, developers, vendors, and users. These wireless technologies provide many connection points to the Internet between mobile phones and other portable handheld devices to earpieces and handsets. These technologies include Wi-Fi hotspots, Bluetooth, WiMAX, wireless broadband Internet (WiBRO), RFID, and others. Wi-Fi hotspots, with a distance and penetration of approximately 50 feet, are physical addresses where people can connect to a public wireless network, such as a cafe, hotel, or airport. WiMAX

is a metropolitan-scale wireless technology with speeds over 1Mbps and a longer range than Wi-Fi. WiBRO, the Korean version of WiMAX, allows users to be connected to the Internet while in motion, even in cars traveling up to 100 kilometers per hour. It is anticipated that users may one day seamlessly switch between networks multiple times per day, depending on the service offered by a specific network service provider.

Many industries have seen the benefits of these wireless technology applications, of which some will be described here. For local, federal, and state agencies, wireless connections provide for GPS functionality, along with real-time vehicle tracking, navigation, and fleet management. For automated logistics and retail industries, RFID tags will give information on just-in-time inventory or shipment location, security status, and even environmental conditions inside the freight. In the health care industry, the wireless applications include patient and equipment monitoring, and telemedicine through the monitoring of an outpatient's heart via continuous electrocardiograms (ECG). Other applications already on the radar: handsets that function as a blood pressure monitor, a blood glucose meter, and wireless pacemaker. One of the hurdles that wireless solution carriers have to overcome is the cost of the devices, and whether insurance companies are willing to cover or share the costs. The wireless technology allows government officials and emergency response teams to stay informed of critical information in the event of an emergency or a disaster that affects wire line services, much like Katrina; these include advanced warnings and public alerts, emergency telecommunications services, global monitoring for environment, and assistance with search and rescue (SAR).

PC World, an online technology magazine, recently reported that the number of Wi-Fi hotspots reached the 100,000 mark globally.[1] Businesses are realizing the value-added service by offering free or paid wireless services to attract customers. Analysts believe that locations such as school campuses and citywide deployment of WiMax technology will benefit users.

a. **United States:** Wi-Fi integration into retail, hospitality, restaurant, and tourism industries has been instrumental for marketing plans, particularly for franchise venues, including Starbucks and McDonald's.
b. **Asia/Pacific:** An article in *The Australian* (2003, March 4) described that 200 restaurants in Australia have migrated away from taking orders via pen and paper to using wireless handhelds to relay orders to the kitchen/bar staff. In addition to offering this type of service, Japan's NTT DoCoMo introduced its iMode Felica handset, enabling users to scan their handsets as their mobile wallets (m-wallets), eliminating the need to carry a credit card, identification, and keys. The feature allows for conducting financial transactions, purchasing services/products, or opening electronic locks.[2] The issue at hand is the different business models of the wireless carrier and that of the credit card companies.

DIGITAL MULTIMEDIA BROADCASTING: CURRENT STATUS AND CONCEPTS

Digital multimedia broadcasting (DMB) is a process of broadcasting multimedia over the Internet or satellite that can be tuned in by multimedia players, capable of playing back the multimedia program.[3] DMB is an extension of digital audio broadcasting (DAB), which is based on the European Eureka 147 DAB Radio standard. DMB technology has two sub-standards: satellite-DMB [S-DMB] and terrestrial-DMB [T-DMB]. While both S-DMB and T-DMB broadcasts television to handheld devices in motion, the difference lies in the transmission method: via satellite versus land-based towers. These real-time transmissions

allow users to view live TV programs, including news, reality shows, or sports games on their DMB cellular phones in the subway.

With mobile growth two or three times that of Europe and North America (Budde, 2002), Japan and Korea have been known for their cutting edge technological innovations and tech-savvy consumers. Korea is one of the world's most broadband-connected countries, with a high penetration rate (Lee, 2003; Shim et al., 2006a; Shim et al., 2006b). The government initiatives have been instrumental in this arena, as the government's hands-on style has created the IT infrastructure necessary to power the latest technological tools. The mobile markets in Japan and Korea have become optimal testing grounds for mobile operators and manufacturers before rolling out products in the rest of the world, given the consumers' insatiable appetite of acquiring the latest technologies, early acceptance behavior, and education fever.

In Asia-Pacific and Europe, considered to be the power houses of the mobile gaming industry, wireless gaming and instant messages have exceeded expectations. In North America, music downloads and e-mails have become essential. As the market for mobile applications, (including short message service [SMS], ring-tones, games, music, videos) is becoming more saturated, more wireless applications have become integrated into most consumer electronics devices, from digital cameras to video game consoles. With over 85% cellular phone penetration rate, Korea introduced the world's first DMB mobile-enabled phone, or "TV-on-the-go" in 2005.[4] While Japan currently provides S-DMB services designed for car receivers, Korea has been the only country to provide full-blown S-DMB and T-DMB services on cellular phones while in motion (including car receivers) by late 2006. With T-DMB and S-DMB services already launched in Korea, several countries in Europe, and the U.S. are planning to launch DVB-H services by the end of 2007. Informa, a consultancy, says there will be 125 million mobile TV users by 2010.[5]

The history of DMB began with the development of DAB services during the mid-1990s in the U.S. and Europe (Korean Society for Journalism and Communication Studies, 2003; Nyberg, 2004). The current status of Mobile TV services in the U.S., Europe, Japan, and Korea is shown in Table 1 (Shim, 2005b).

Table 1. Current status of mobile TV services in various countries

Country	USA		Europe		Japan	Korea	
Mobile TV technology	MediaFlo	DVB-H	DVB-H	T-DMB	S-DMB	S-DMB	T-DMB
Receiving device	Car receiver	Car receiver	Mobile TV- phone, Car receiver	Car receiver	Car receiver	Mobile TV- phone, Car receiver	Car receivers
Service launch date	2006	2006	2006	2006	2004	May 2005	Dec 2005

Sources: The Korea Times, (2005, January 18) "Korea's Free Mobile Broadcasting Faces Snag".
KORA Research 2003-10,. (2004, May). "A Market Policy Study on DMB".
M. H. Eom, "T-DMB Overview in Korea," (2006, April). Proceedings of 2006 Wireless Telecommunications Symposium, Pomona, CA,

As shown in Figure 1, DMB program producers provide a variety of programs and content to the DMB center, which broadcasts through either satellites or towers. Thus, the DMB cellular phone users receive content and programs through satellites, towers, or "gap-fillers" (small base stations) to ensure there are no reception problems, even in underground subways (Shim, 2005a).

Consumers are increasingly gravitating towards customized devices and features, as a miniaturized interactive entertainment center is packaged into the cellular phone, complete with an MP3 player, multi-megapixel camera, digital video recorder, CD-quality audio, and a selection of satellite broadcast television and audio channels (Olla & Atkinson, 2004) as they can choose from television and audio on-demand and simultaneously make phone calls. The mobile TV-enabled phone, equipped with these features, has become more than integrated into one's lifestyle, as it becomes an extension of the consumer's identity. The handset carriers are in the process of yet again trying to capitalize on producing fashion-forward phones and portable gaming consoles.

DMB data service is a framework of the following groups: data provider, audio/video content producer, DMB producer, advertiser, and customer. A schematic view of DMB data service and the components, shown in Figure 2, provides a basic understanding of the general structure of the DMB business model. The figure also shows interaction of the DMB producer with other groups of DMB data services.

For example, the DMB producer provides various content and programs to customers for a service fee. The DMB producer charges an advertising fee to the advertiser, from whom customers can purchase directly for advertised services via the DMB device. The audio/video content producer and data provider each provide various contents to the DMB producer for a fee. The perceived richness of the medium should have an impact on the use of the communication medium (Daft & Lengel, 1986; Smagt, 2000). The rich media is more appropriate in ambiguous communications situations, which emphasizes Daft and Lengel's valuable contribution of placing equivocality high in the business and information systems field.

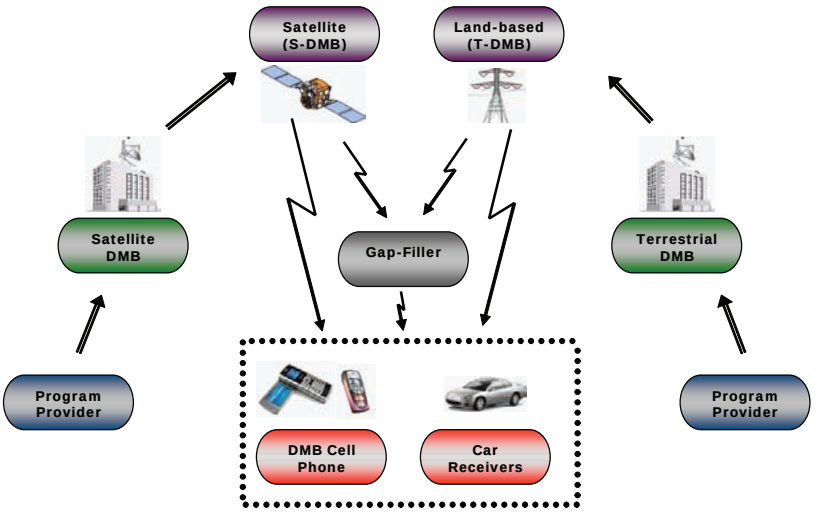

Figure 2. A schematic view of DMB data service business model

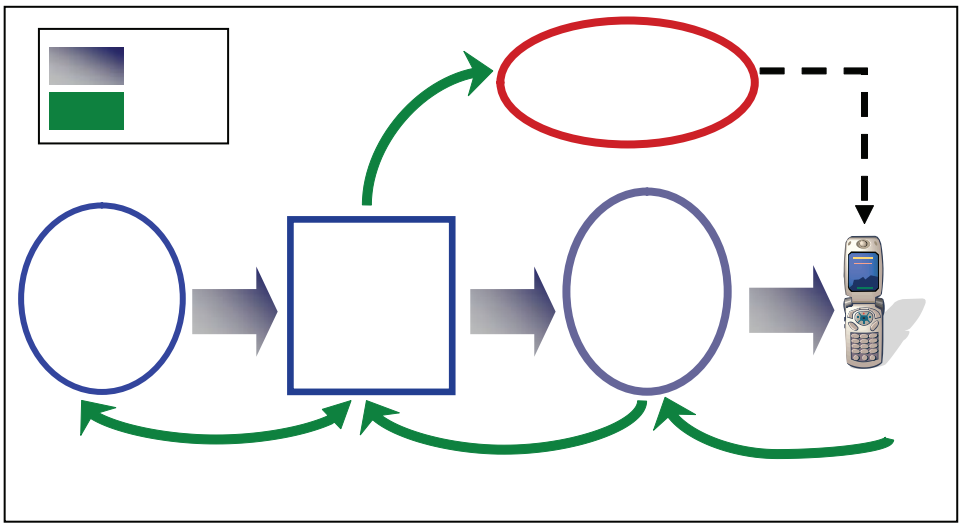


Source: Modified from KORA Research 2003-10. (2004, May). "A Market Policy Study on DMB," Research Report of Korea Radio Station Management Agency.

There exists a rich body of knowledge of technology adoption and diffusion, including the digital multimedia broadcasting technology. For example, several theoretical backgrounds, such as institutional theory, technology acceptance model (TAM) (Venkatesh & Davis, 2000), and diffusion of innovation theory (Gharavi, Love, & Cheng, 2004; Rogers, 1983) explain the DMB technology adoption at an individual, organizational, and industry level (Lee, 2003; Shim, 2005a, 2005b). Among the theories, Lee and Shim both describe the major factors behind Korea's information and communication technology diffusion such as: external factors (global economy, government policies), innovation factors (usefulness, ease of use, self-efficacy), and imitation factors (subjective norm of belongingness, word of mouth). The authors believe that either the diffusion theory (such as external, internal, and mixed influence models), or TAM (such as perceived usefulness and perceived ease of use), or the combination of both can be applied behind DMB cellular phone adoption and diffusion.

RESEARCH METHODOLOGY

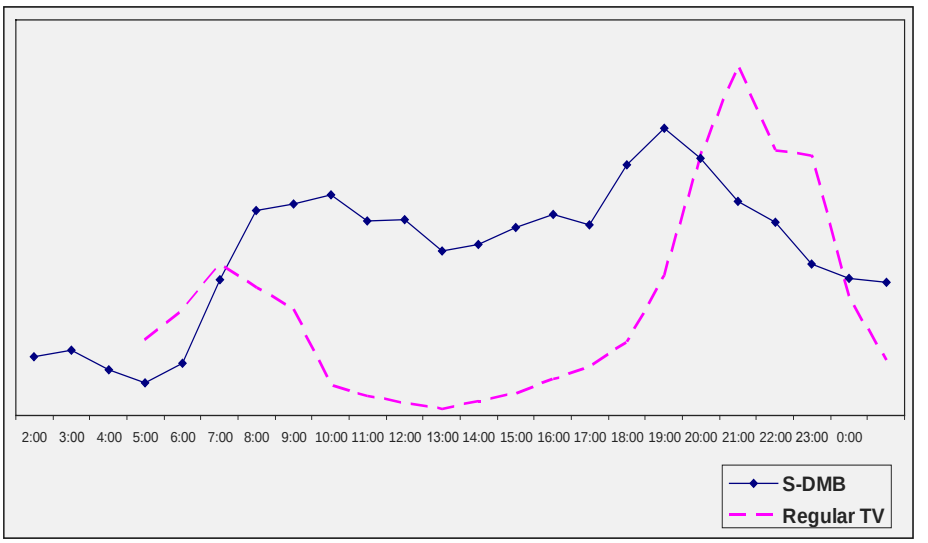
A recent study demonstrates a higher number of DMB viewers than regular TV viewers during the daytime (Figure 3). Since the DMB cellular phone captures the content-on-demand aspect, the DMB phone service (S-DMB) are optimal for the on-the-go daytime enthusiasts.

To determine how integral DMB phones have been and will be in consumers' daily lives, the authors conducted qualitative and quantitative analyses. Study Phase I describes the use of the qualitative research method, specifically the existential phenomenological method. Study Phase II describes the quantitative research methods including the survey questionnaire (Shim, Shin, & Nottingham, 2002).

STUDY PHASE I: QUALITATIVE ANALYSIS

Although quantitative instruments serve as valid methods to study the perceived use of DMB

Figure 3. The percentage of viewing on S-DMB vs. regular TV



Source: Suh, Y. (2005, November). "Current Overview of S-DMB," TU Media.

phones, qualitative research methods, such as interviewing, can reveal the function of variables perhaps overlooked by survey designers. The current project was designed to employ the qualitative technique of existential phenomenology. Thus, it develops an in-depth understanding of the new concept of DMB usage by investigating respondents' reports of their DMB phone usage experiences. With this data collection technique, the respondent is encouraged to describe in-depth the personally experienced phenomenon (Thompson, Locander, & Pollio, 1989).

Existential phenomenology was selected among various qualitative methods, such as case studies and ethnography, because of its attention to a respondent's individualistic, subjective expression of an actual live experience of the situation of interest. Such reflection on a single experience encourages the perceiver to focus on nuances that would likely escape the broader brush of a researcher's selection of choices among a pre-set list of quantitative dimensions or escape even the surface comparison of reports of respondents' experiences. Existential phenomenology encourages the respondent to consider specific and live events. The goal is to discover patterns of experiences (Thompson et al., 1989).

Since the purpose of existential phenomenology is to describe the experience as it is lived, the interview has been found to be a powerful tool for attaining in-depth understanding of another person's experience (Kvale, 1983). Research analysis of interview-derived information is considered valid because the respondents' own words are used to understand their experiences (Feagin, Orum, & Sjoberg, 1991). Accordingly, respondents in this research were presented with a set of open-ended questions designed to encourage them to discuss and describe their experiences with DMB phone usage. To determine a specific set of key factors that would be of critical concern to DMB users, 19 respondents in Korea were enlisted in Study Phase I.

A purposive sample is deemed appropriate for exploratory research designed to query respondents who have experienced a phenomenon of interest. Thus, the networking technique was utilized to obtain a purposive sample of individuals who had interacted with the DMB cellular phone services. These respondents were then

asked to name additional individuals who had experienced DMB services. Thus, aside from the requirement of the respondents' familiarity with the DMB services, demographic characteristics of the sample resulted by random chance.

The majority of respondents were well-educated young professionals with a zealous tech-gadget nature, affluent, computer proficient, and somewhat knowledgeable about DMB services. Although this sample clearly is not representative of the population at large, the sample profile corresponds with what the authors presumed to be identified as a typical DMB service user. Thus, the experiences relayed by these respondents are considered to be a reasonable representation of a random sampling of regular DMB cellular phone users. After respondents were assured of confidentiality and protection of their privacy, each tape-recorded interview lasted 20-30 minutes. Each interview began with open-ended questions posed in a conversational format to encourage the respondent to develop a dialogue with the interviewer, providing the context from which the respondent's descriptions of his or her own DMB service experience could flow freely and in detail. Participants were encouraged to discuss not only their DMB services experiences, but also their attitudes and perceptions regarding negative and positive aspects of DMB services.

Such in-depth descriptions have been found to be beneficial in revealing emotional and behavioral underpinnings of overt user behavior. In reality, the act of a respondent's description of a specific experience in-depth, frequently results in further personal insights that arise through the revival of the experience. The respondents were asked to describe their main reasons for purchasing DMB cellular phones, which varied: "to gain information access," "to spot the latest trends," "for education or entertainment," "to watch TV while commuting," and "for movies, dramas, and shopping." Their personal positive experiences were: "mobility—a deviation from a fixed location point," "high quality reception," "convenience," "accessible anytime/anywhere," "lifestyle change," "great for commuting," and "good for managing time." On the other hand, the negative aspects they experienced included: "expensive device," "reception problem," "low battery hours with limited usage time (e.g., 2-3 hours)." Most respondents reported that the following areas would have great potential for future DMB applications and content: information access, education/learning, e-trading, retail, tourism, and entertainment. In Study Phase II, these themes were reconstructed to set up independent variables for the quantitative analysis.

STUDY PHASE II: QUANTITATIVE ANALYSIS

To determine the extent to which DMB phones are being used as the latest multimedia product, the authors developed a questionnaire. DMB has a wide array of advantages: personalized, live media (television, radio, or data broadcasts) that can be viewed on-demand anytime; the mobility of the phone which receives satellite and terrestrial television broadcast signals even at high speeds or underground; and an interactive handset into which one can speak via the handset while watching TV programs. The research instrument underwent two pretests. The first pretest involved administering the questionnaire to 25 graduate and undergraduate students at a large university in Seoul, Korea. The questions, which concerned price, usage time, program content, and services were modified to reduce the effects of proximity bias on the responses, with several questions reworded for clarity. The second pretest was conducted at a DMB phone service provider company to ensure the content validity. A five-point Likert scale was used for recording the responses.

DMB will not be successful if content and service providers fail to provide high quality service, a variety of content, and reasonable prices for services and handsets (Teng, 2005).

Several research studies demonstrated that there are differences among age groups on factors such as technology adoption and usage (Larsen & Sorebo, 2005; Ventatesh, 2000). It is believed that older generations are more anxious about the use of technologies than the younger generations. A number of research studies have supported this belief (Gilbert, Lee-Kelley, & Barton, 2003). Based on the theories and research questions along with Study Phases I and II, the authors developed the following six hypotheses:

H_1: The user's easy access to DMB service is perceived as a satisfactory service offered by the DMB service provider.

H_2: Premium (excellent) content of DMB programs corresponds with a good quality DMB service provider.

H_3: There is a difference between different age groups and their perceived value of DMB handset price.

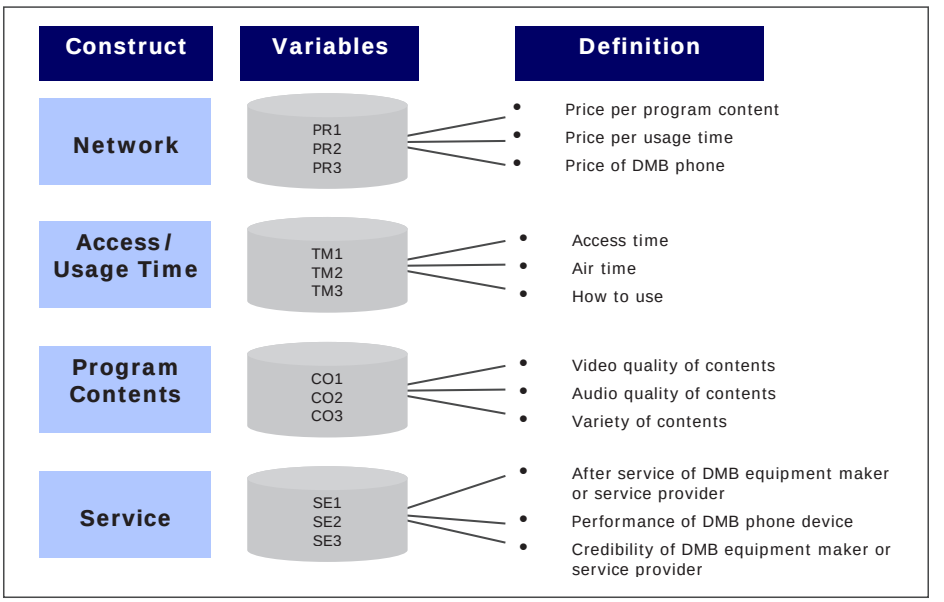
H_4: There is a difference between different age groups and their perceived value of DMB phone usage time.

H_5: There is a difference between different age groups and their perceived value of DMB program content.

H_6: There is a difference between different age groups and their perceived value of DMB services.

The authors and their research assistants distributed the questionnaire to 300 randomly selected individuals inside the Korea Convention Exhibition Center (COEX) and Korea World Trade Center during January and February 2005. Of the 300 randomly selected individuals' responses, 264 were valid. The two-page questionnaire was divided into three sections with a total of 32 questions. In Section 1, the authors asked the randomly selected participants about DMB services, such as information sources about DMB services, user satisfaction ratings, influential factors when choosing DMB services, DMB applications, and others. The questions in Section 2 covered the participants' perceived values of DMB application services. Section 3 inquired of participants' demographics.

Table 2. Model construct



DATA ANALYSIS AND FINDINGS

The 264 usable research instruments collected from the respondents were well represented in terms of gender, age, and occupation. Statistical Package for the Social Sciences (SPSS) was used to calculate descriptive statistics and perform a confirmatory factor analysis. The respondents' primary occupations included: students (51.9%), IT staff (15.2%), government employees (13.3%), professionals (7.6%), self-employees (4.1%), housewives (3%), and others (4%). Approximately 73.8% of the sample respondents indicated that they had either undergraduate (64%) or graduate school (9.8%) education.

The respondents were well represented in terms of gender and age. About 30% of the sample respondents had not heard about DMB. Of the 70% of respondents who had heard about DMB, the main sources included: TV (26%), newspaper (20%), Internet (15%), friends (6%), and others (33%). About one-fifth (20.1%) of the respondents were utilizing DMB services. Of those respondents, 62.2% were satisfied with their current DMB service whereas 30.3% were only satisfied on a mediocre level. In other words, only 7.5% of the current DMB users were not satisfied with their DMB services. The current users accessed their DMB phones for news and information; leisure and tourism; public relations (marketing); shopping; games; and education. The users believed that the DMB services would impact service industries such as tourism and retail.

The results also indicated that among the sample respondents, the non-users felt that the following major factors would be taken into consideration when choosing DMB services for the future: (1) pricing of DMB cellular handset, (2) video quality, (3) program content, (4) quality [of DMB cellular handset], (5) ease of use, and (6) others [e.g., customer service by the DMB cell phone manufacturer or service provider; brand image and perception]. The aforementioned results from the sample respondents were very astonishingly similar to the 19 interviewees' perceived values.

The independent variables that determine DMB services are: price, usage time, and program content. The dependent variable is DMB service. Table 2 provides a definition of each of these variables. The reliability measure (construct validity) for these constructs was Cronbach's coefficient (alpha). Even though the general rule of thumb for reliability is a value of 0.8 (alpha), values of 0.6 or 0.7 may be considered adequate in some cases (Hair, 1998). Overall, the model provides a valid representation of the data and the constructs are reliable. The reliability test generated Cronbach's coefficient alpha of .7343 for the 12 items. From the analysis, it was concluded that the measure of 12 items was reliable. Coefficient alphas for the four constructs are shown in Table 3.

A series of principal components factor analyses using a VARIMAX rotation were used to assess the unidimensionality in this study. Eigenvalues of at least 1.0 were used to assess the number of factors to extract. The dimensionality of each factor was assessed by examining factor loadings. Factor loadings on construct are shown in Table 4.

Assessing dimensionality involves examining the inter-correlations among the major constructs. A correlation matrix for the constructs is shown in Table 5. The inter-construct correlation coefficients were all positive and significant at less than 0.01 (see Table 5).

The *t* test was used in the quantitative analysis. The price factor of the DMB phone usage is not an issue if the user perceives the DMB program content to be valuable. Table 6 also showed that DMB service was affected by program content (beta=0.358, t-value=5.689). The users associate easy access/connection time to the DMB services with reliability provided by DMB equipment makers or service providers (beta=0.300, t-value=5.104). H_1 and H_2 were supported. ANOVA and Duncan test were used to evaluate hypotheses H_3, H_4, H_5, and H_6.

DMB PHONE PRICE AND RELATED FEES

The users were asked to rate the importance of price issues of the DMB handset and related service fees when selecting a DMB cell phone. These issues include price per program content, price per usage time, and price of the DMB handset. The mean response among the teens was 4.46 (on a scale of 1=unimportant and 5=very important); 4.23 for 20s, and 4.33 for 30s. The mean response among the older generations (40s and older) was 4.0. Table 7b showed that there were significant differences among teens and the other age groups (20s, 30s, 40s, and older). And the 20s and 30s age group perceived the DMB phone price and related fees differently, when compared with teens, and the 40s and older age group.

In an effort to explain this unexpected finding, the authors used analysis of variance (ANOVA) to see if there were any significant differences between the DMB handset price/related fees and age group. As shown in Table 7a, the difference is statistically significant (F=12.583, df=3, 260, p=0.000), which demonstrates that the younger generation is willing to pay the current market price for the DMB handset and related services, given that they perceive the content to be useful and worthwhile. This supports H_3, as it validates that there is a difference between the age groups and their perceptions of DMB phone price.

ACCESS/USAGE TIME

The users were asked to rate the importance of access/usage time issues of DMB services and handset when selecting a DMB cellular phone. These issues include access time, air time, and the time it takes to get familiarized with the DMB handset and services. The mean response among the teens was 4.02 (on a scale of 1=unimportant and 5=very important); 3.82 for 30s, 3.86 for 40s and older. Table 8b demonstrates a slight discrepancy between teens and those in their 20s, but no significant divergences among other age groups (30s, 40s and older). The ANOVA test showed that there was not a significant difference between age groups and their judgments of the importance placed on the DMB access/usage time (see Table 8a). This does not support H_4, as it validates that there is no difference between age groups and their percep-

tions of the DMB phone access/usage time. When focusing on strategic moves, the major players in the DMB market do not have to place as much emphasis on the end-users' access/usage time.

PROGRAM CONTENT

The users were asked to rate the importance of program content of DMB handsets when selecting a DMB cellular phone. These issues include video quality of content, audio quality of content, and a selection of content. As shown in Table 9a, the ANOVA test showed that there was a difference between various program contents and age groups ($F = 6.30$, $df = 3, 260$, $p=0.000$). The mean response among the teens was 4.69 (on a scale of 1=unimportant and 5=very important); 4.29 for the 20s age group, 4.30 for the 30s age group, and 4.32 for the 40s age group and older. Table 9b showed significant deviation between teens and the other age groups (20s, 30s, and 40s and older).

Sig.		.743	1.000

9b. Duncan Test

The perception on program content for each age group (20s, 30s, and 40s and older) differed from the teens' perceptions. This supports H_5.

SERVICE

The users were asked to rate the importance of DMB services when selecting a DMB cellular phone. These services include after-service of the DMB equipment maker or service provider, performance of the DMB phone device, and the credibility of the DMB equipment maker or service provider. As shown in Table 10a, the ANOVA test showed that there was a difference between the age groups and their approach to the importance of DMB services ($F = 3.355$, $df = 3, 260$, $p < 0.019$). The mean response among the teens was 4.54. Table 10b showed that there are significant differences among teens and other age groups (20s, and 40s and older). And each age group's (20s, and 40s and older) perception on services deviated significantly from the teens' perceptions. This supports H_6.

As shown previously, all hypotheses (except H_4) were supported.

ACTUAL USAGE AND IMPLICATIONS

Although the exploratory study's results showed teens and the 20s age group as heavy users of DMB services, the actual DMB statistical usage data (see Figure 4) differed. The actual usage data was recently released from TU-Media (S-DMB service provider), which revealed that those in their late 20s, 30s, 40s, and 50s represent a large percentage of users of the following DMB services: soap operas, sports, and music program content (Suh, 2005). The results in Figure 5 show a correlation between preferences across age and gender. While the sports channel was the only preferred program among males to spread across all age groups, soap opera programs were preferred by female teens and those in their 20s. The authors believe that there are several reasons as to why the younger consumers may not be currently subscribed to S-DMB services: (1) S-DMB handsets (which retails for $600-$800) are too expensive; (2) The teens lack the extra out-of-pocket money to pay for the S-DMB $13 monthly service fee (and $20 activation fee); and (3) The parents do not feel justified in purchasing a DMB handset for their

children's TV and gaming purposes. Additionally, most of the school-age children have little time to watch DMB program content due to the academic load. Furthermore, the actual usage results among various demographic groups for T-DMB services, once released, are expected to differ from that of S-DMB services given that T-DMB services are free and advertiser-supported.

CONCLUSION

The mobile TV standards (e.g., DMB, DVB-H, and MediaFLO) and wireless technologies will add a new dimension to the connectivity between enterprises and consumers as well as their access to information and entertainment. Given the demand for ubiquitous computing in an impatient,

technology-hungry, instant gratification-seeking population, the desire for mobile TV will continue to grow and soon mobile TV will be synonymous to today's radio in the long run (Kim, 2004). Similar to the interactive TV (iTV) (Tsaih, Chang, & Huang, 2005), the DMB has implications, which include: (1) service and content providers use the DMB as a vehicle for business-to-consumer (B2C) commerce via programs, content, and services; (2) consumers have real-time access to DMB services and programs on mobile phones, PDAs, and other mobile devices anytime and anywhere.

As mentioned earlier, the key issues for the DMB market include: (1) optimal capital investment levels to achieve adequate service coverage for T- DMB and S- DMB services; and (2) appropriate business models, with respect to advertising-supported vs. subscription services. The wireless mobile service industry has very complex issues, which span across technical, logistical, social, and cultural issues (Trappey, Trappey, Hou, & Chen, 2004). Thus, this requires cooperation among the cellular and network service providers, service developers, and equipment makers to collaborate with the government and users to create growth in the cellular telecommunications industry.

Although this research is based on exploratory methods, it still has its limitations. For example, the sample size was collected during the experimental/trial stages of S-DMB services in Korea. The authors reinforce the continuation of this research to solidify findings with an increased sample size of respondents collected during the actual stage of S-DMB and T-DMB services. In addition to this belief, the authors endorse the notion of longitudinal studies conducted to obtain more results. Furthermore, the authors strongly believe that the findings from this exploratory research will be valuable for the DMB service and content providers to gain insight into various age groups and their perceptions.

One of the implications of this paper of wireless mobile technologies and mobile TV is to demonstrate how important the government initiative can benefit less-developed and developing countries. For example, South Korea's Ministry of Information & Communication (MIC) established the "IT839" Strategy—"8" services; "3" infrastructures; "9" growth engines—as a roadmap for Korea's future IT development plan (MIC, 2005). The authors hope that this discussion will be beneficial for the mobile wireless industry and the academia for insight and understanding of the trends of the ubiquitous computing era.

Chapter 1.15
Motivations and Barriers to the Adoption of 3G Mobile MultiMedia Services:
An End-User Perspective in the Italian Market

Margherita Pagani
I-LAB Centre for Research on the Digital Economy, Bocconi University, Italy

Danilo Schipani
Valdani Vicari & Associati, Italy

ABSTRACT

This chapter provides an end-user perspective on mobile multimedia services that are likely to emerge with the roll out of Third Generation Mobile Services (3G). More specifically, the objectives of the study are:

- To provide an insight into current behavior in terms of attitudes towards, access and usage of multimedia mobile services by current end users;
- To establish main clusters of mobile users;
- To investigate the possible motivations and barriers of usage of new mobile multimedia services as viewed by current users.

The remainder of this chapter is organized into the following four sections. The first section provides a brief review of the literature on the technology acceptance model. Next we present our research model based on a qualitative exploratory survey conducted in six markets. Then we test the proposed model on the Italian market and present the analysis and results of our study. Finally we make conclusions by discussing the implications of our study, followed by presenting future research directions.

INTRODUCTION

As telecommunications move into an era where the distinction between voice, video and data will be

blurred, convergence of communications, information, entertainment, commerce and computing will lay the foundation for the development of an Information Society.

Over the last five years there have been a number of significant developments in multimedia computing power, CD-ROM technology, digital television, the Internet/Intranet, IP-based services, and terrestrial and satellite mobile communications, which could have a profound impact on our society. These technologies and systems may enable dramatic changes to take place in working practices, entertainment, education and health care.

Many organizations within the computing, entertainment, and communications industries are now looking to identify and capitalize on the promise of new market opportunities in multimedia created by these developments.

However, demand for multimedia services, should they be successful, is unlikely to be constrained to the fixed network. Greater pressure on time, and the need for flexibility and responsiveness in business, will lead to a growing demand for access to these services anytime, anywhere.

In order to meet the evolving needs of customers, and to capture the opportunity which this evolution represents, the mobile industry is looking to define and develop a third generation of mobile technology that will take the personal communications user into the Information Society by delivering voice, graphics, video and other broadband information direct to the user, regardless of location, network or terminal.

The purpose of the chapter is to provide an end-user perspective on mobile multimedia services that are likely to emerge with the roll out of Third Generation Mobile Services (3G).

The remainder of this chapter is organized into the following four sections. The first section provides a brief review of the literature on the technology acceptance model. Next we present our research model based on a qualitative exploratory survey conducted in six markets. Then we test the proposed model on the Italian market and present the analysis and results of our study. Finally we make conclusions by discussing the implications of our study, followed by presenting future research directions.

TECHNOLOGY ACCEPTANCE MODEL (TAM): THE THEORETICAL BACKGROUND

Information Systems (IS) researchers have made significant efforts in building theories to examine and predict the determinant factors of information technology (IT) acceptance (Agarwal & Prasad, 1998, 1999). Existing models of IT acceptance have their foundations from several diverse theories, most noticeably innovation diffusion theory, where individuals' perceptions about using an innovation are considered to affect their adoption behaviors (Agarwal & Prasad, 1998; Moore & Benbasat, 1991; Rogers, 1995). Other important theoretical models that attempt to explain the relationship between user beliefs, attitudes, intentions, and actual system use include the theory of reasoned action (TRA) (Ajzen & Fishbein, 1980), the theory of planned behavior (TPB) (Ajzen, 1991), and the technology acceptance model (TAM) (Davis, 1989; Davis et al., 1989). Although there are numerous studies in the field of adoption and diffusion of marketing-enabling technology (Daghfous, Petrof & Pons, 1999; Holak & Lehman, 1990; Labay & Kinnear, 1981; Plouffe, Vandenbosch & Hulland, 2001; Rogers, 1995), previous work has mainly focused on the adoption of products and technology (Au & Enderwick, 2000; Davis, 1989; Eastlick & Lotz, 1999; Verhoef & Langerak, 2001). In contrast, the perspective on services and service-enabling technologies is considerably less pronounced. Despite the fact that several trend studies have been conducted regarding the potential of wireless technology and 3G services (Durlacher, 2001; UMTS Forum, 2001), there

exists a need for more substantive, theory-based research, creating a more in-depth understanding of consumer behavior with regard to m-commerce. In the information system literature on IT adoption, researchers have conducted several studies to examine the relationship between perceived ease of use, perceived usefulness, and the usage of other information technologies (Adams et al., 1992; Chau, 1997; Davis, 1989; Davis et al., 1989, Hendrickson & Collins, 1996; Mathieson, 1991; Szajna, 1996). Their researches have supported the Technology Acceptance Model (TAM) proposed by Davis (1989), which posits that perceived ease of use and perceived usefulness can predict the usage of technology.

TAM was derived from the Theory of Reasoned Action (TRA). According to Davis (1989), perceived usefulness and perceived ease of use are the two determinants that influence people's attitude toward IT usage intention and actual IT usage. Perceived usefulness is defined as "the degree to which a person believes that using a particular system would enhance his or her job performance" and perceived ease of use is defined as "the degree to which a person believes that using a particular system would be free of effort" (Davis, 1989, p. 320). Davis and his colleagues (Davis, 1989; Davis et al., 1989, 1992) demonstrated that perceived ease of use affected usage intention indirectly via perceived usefulness.

In an extension to TAM, Davis and his colleagues examined the impact of enjoyment on usage intention (Davis et al., 1992). They reported two studies concerning the relative effects of usefulness and enjoyment on intention to use and usage of computers. As expected, they found enjoyment had a significant effect on intention. A positive interaction between usefulness and enjoyment was also observed.

Several recent empirical studies have validated adoption theory in relation to a wide range of products (Holak & Lehman, 1990; Labay & Kinnear, 1981; Ostlund, 1973; Rogers, 1995) and technology (Beatty, Shim & Jones, 2001; Plouffe et al., 2001). A large number of studies have investigated the use of electronic commerce, but the field of mobile commerce has been left virtually unexplored. In this research our goal is to extend the TAM model to study motivations and barriers to the adoption of 3G mobile multimedia services. In the following sections the research is divided into two stages: an exploratory qualitative stage followed by a quantitative stage focused on the Italian market.

RESEARCH FRAMEWORK

Methodology

Many factors positively or negatively influence users' adoption of multimedia mobile services. In this section we identify several variables that influence adoption of 3G mobile multimedia services. The variables are derived from two preliminary pilot studies realized on a sample of young people in Italy and USA followed by an exploratory qualitative study conducted by Nokia through 24 focus groups in six markets (Brazil, Germany, Italy, Singapore, UH, USA).

The second stage of the analysis concentrates specifically on a quantitative marketing research. Data were gathered by means of a questionnaire. The population consists of 1,000 Italian users of mobile services. It tries to describe behaviors, roles and test variables influencing adoption of mobile computing. We consider Italy because it is the European country with the higher penetration of mobile phones and profitability, and it is also prone to market innovation.

The main goal of this research is to identify a hierarchy of importance concerning the critical factors influencing the adoption of mobile services. To realize this research objective, conjoint analysis was seen as the appropriate statistical tool.

Table 1. Fieldwork details

Country	Sample	Field times
Brazil	Nationally representative o f adults aged 1 8-64 w ho a re e conomically active	6th – 20th March 2001
Germany	Nationally r epresentative of adults aged 14+	23rd March – 5th April 2001
Italy	Nationally r epresentative of adults aged 15+	23rd March – 5th April 2001
Singapore	Nationally representative o f adults aged 15-64	13th – 26th April 2001
UK	Nationally representative o f adults aged 15+	23rd March – 5th April 2001
USA	Nationally r epresentative of adults aged 18+	21st – 30th March 2001

Conjoint Analysis

Conjoint analysis is a technique that allows a set of overall responses to factorially designed stimuli to be decomposed so that the utility of each stimulus attribute can be inferred from the respondent's overall evaluations of the stimuli (Green, Helsen & Shandler, 1988). A number of (hypothetical) combinations of service elements can be formulated that will be presented to a sample of customers. According to Lilien and Rangaswamy (1997), the analysis comprises three stages.

The first stage is concerned with the design of the study, where the attributes and levels relevant to the product or service category will be selected. In the second stage customers rate the attractiveness of a number of possible combinations of customer service elements. Finally, in the third stage, ratings are used to estimate part-worth utilities, that is, the utility that is attached to the individual levels of each service element included in the research design. Consequently, an accurate estimate of customer trade-offs between services elements can be obtained.

The dependent variable in our study was the intention to make use of mobile services.

Exploratory Qualitative Stage

The fieldwork has been carried out face to face in the first and second quarters of 2001 through 24 focus groups conducted by Nokia Networks in six markets (Brazil, Germany, Italy, Singapore, UK, USA). The interviews focused in on the core target for the 3G offering, namely, teenagers, young adults and family adults, all currently using mobile phones for personal usage. The sample was segmented by age, 16-19, 20-29 and 30-45, and by life stage.

The research looked primarily at the following mobile multimedia services: photo messaging, mobile e-mail, video messaging and postcard messaging. However, the research also briefly touched on rich text messaging, and on video calling.

Of utmost importance in the study was to ensure that the respondents concentrated on the messaging format, and did not allow previous misconceptions about service or delivery of the service. They were therefore told to imagine that there would be no network problems, and not to concentrate on pricing.

The prompted statements offered to the sample as motivations for usage of the future multimedia mobile services can be classified to form eight broad segments of usage (Table 2):

Table 2. Motivation segmentation

1. Business
for business purposes
2. Formality
When I want to send a formal message
3. Urgency
When I need to know the message has arrived
When I want to send urgent communication
As a rapid way to stay in touch
4. Function
To send a long piece of text
To send an attachment
When I don't feel like talking
Practical reason (like to show something I want to buy)
5. Price
When I want to communicate cheaply
6. Discretion
Need to be discreet and quiet
When talking would disturb people around me
Might disturb the person I'm trying to contact
7. Personal contact
To keep in touch with friends/family abroad
To send an intimate message
To contact people I don't see very often
As a personalized way to send a message
To increase the feeling of contact
To share an experience
Nice for people to see me if they haven't done so for a while
For longer greetings
When I don't want to talk, but need to communicate
8. Fun
Joke or chit-chat with friends
As a novel way to message
To share an experience
As it is just great fun
To send pictures from my holiday
To show something like a view
To express creativity

1. Business
2. Formality
3. Urgency
4. Function
5. Price
6. Discretion
7. Personal Contact
8. Fun

The research model to be empirically tested in the Italian market is illustrated in Figure 1. The model is derived from the theories and hypothesis described in the preceding section. The relationship constituting the model also has support from prior theoretical and empirical work in the exploratory qualitative stage.

Exploratory Quantitative Stage

A following stage of analysis concentrates specifically on a quantitative marketing research conducted in the second quarter of 2002 through questionnaires on a sample of 1,000 Italian users of mobile (sampled among over 18 Italians).

One thousand interviews provide a sampling error (at 50%) of 3.1% (with a probability level of 95%).

The research, managed through telephone calls, tries to describe behaviors, roles and variables influencing adoption of mobile computing.

The results of the quantitative marketing research are now summarized. This research was structured in order to deepen the motivations and barriers towards the innovative services delivered through 3G mobile services, the eventual levels of demand and usage and the content types and formats that consumers express opinion for.

Key items in the questionnaire used for analyzing the survey are as follows:

1. **Degree of service innovation** perceived by consumers. Respondents selected their answers from a list of innovative services categories;
2. **Interest** for the services categories under scrutiny;
3. **Preference** for means/platforms through which selected services can be accessed (portables, phone and/or TV);
4. **Analysis** of key features of services (ease of use, speed, cost and usefulness);
5. **Ranking** of services features.

Figure 1. Adapted TAM model on the adoption of multimedia mobile services

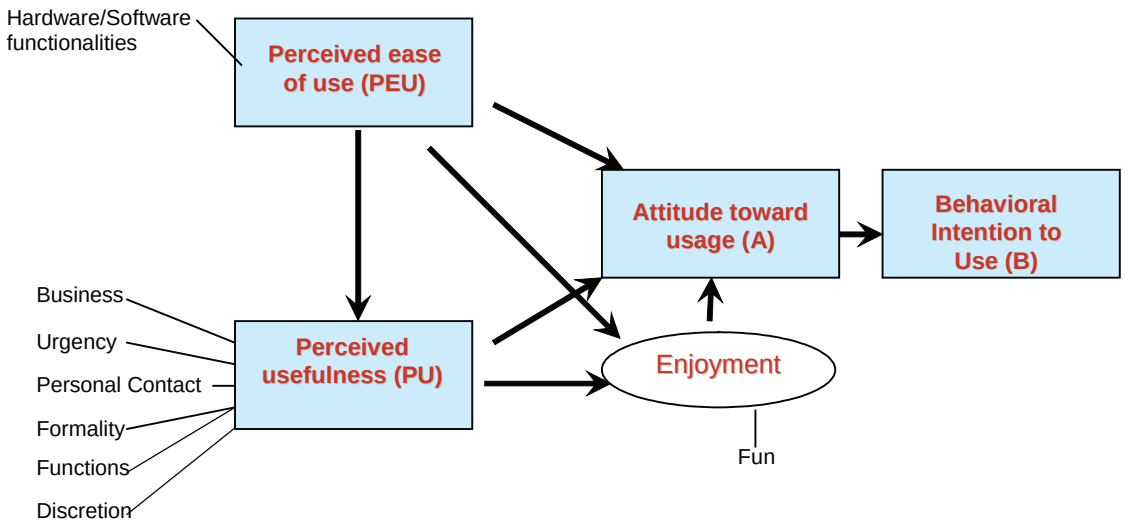

Figure 2. Composition of the sample

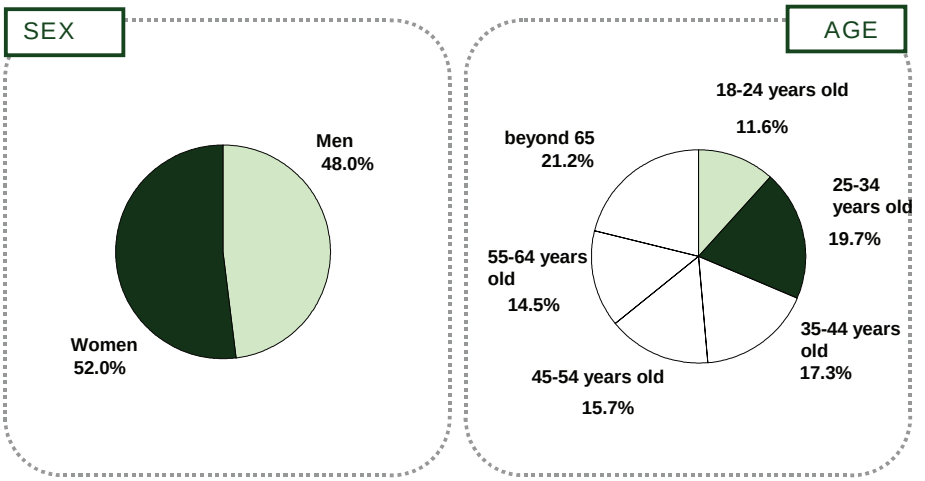

The services considered in the questionnaire are the following:

- Interactive and real-time entertainment;
- Data exchange among people and between people and various electronic devices;
- Contextual and real-time shopping;
- Portfolio and personal funds management;
- Safety-related services;
- Location-based services.

All the services have been considered rather innovative (the average is 7.1 on 1 minimum -9 maximum scale).

In terms of the interest expressed towards these services, the sample distributes are shown (see Figure 3).

Table 3 shows the main features preferred by the people to be attracted to use these services.

"Usefulness" and ease of use are considered the most important variables in order to access the segments of population and, as shown in Figures

Figure 3. Interest expressed towards multimedia mobile services

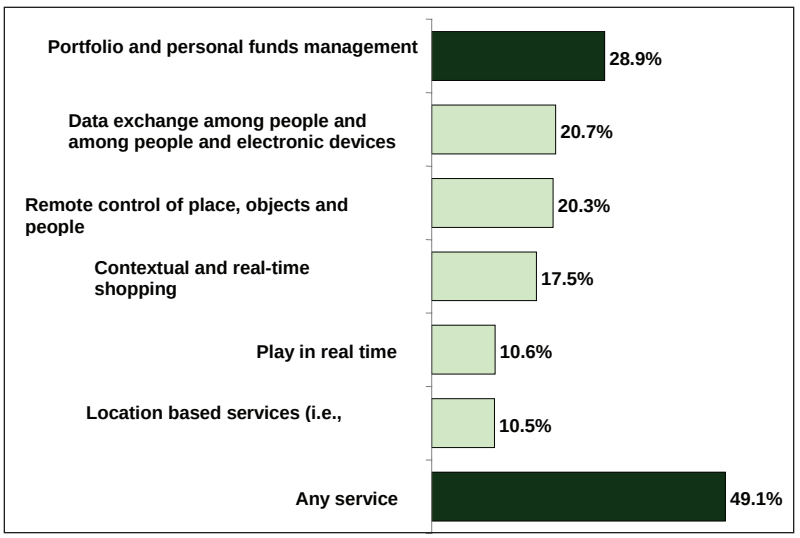

Table 3. Features preferred

	IMPORTANCE	
	Ranking	%
Usefulness	**1°**	31.3%
Ease of use	**2°**	26.7%
Price	**3°**	23.8%
Speed of use	**4°**	18.2%

4 and 5, there are different meanings assigned to these words.

The final objective of the research was to identify the key descriptive elements of homogeneous segments of the population. This is relevant in order to define the right strategies to offer the new services in the proper and differentiated way.

The most statistically powerful variable in order to distinguish the behaviors of people is the degree of interest towards the innovative services.

If we then clusterize the sample using this variable, and cross it with the socio-demo data, it turns out that the kind of activities performed in life by the consumers is the strong predictor of their future use of the new services.

In particular, it is possible to describe two different segments as indicated in the following figure:

- Cluster 1 is composed of people who declared they are not interested in the new services;
- The remaining 51% can be divided in two groups that are different in terms of the way firms should approach them to sell the new services.

The two segments are:

- The "professionals," that is, people who mainly are managers or entrepreneurs in life, who are 38% of the interviewed base;
- The "students," who account for the remaining 13%.

The purpose is now to identify the variables network operators can use to access the identified clusters. This is an essential piece of information for crafting the right strategies in order to "catch" the segments.

The "professional" segment is made of people who look for *usefulness* as the almost exclusive

Figure 4. Meaning of usefulness

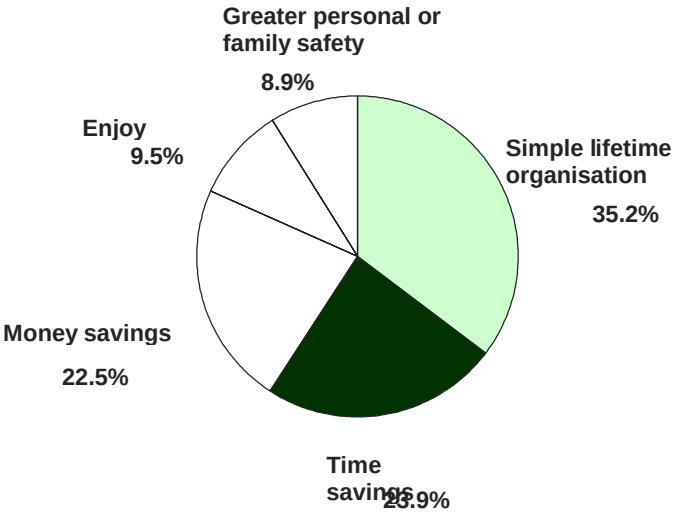

Figure 5. Meaning of ease of use

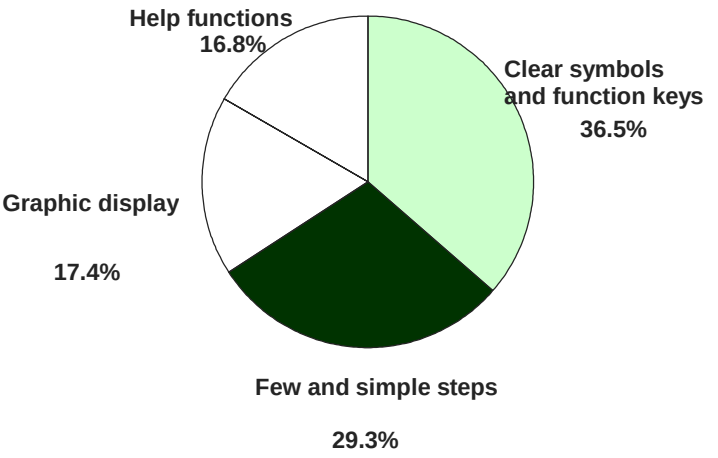


variable in order to access and pay for the service.

The "students" segment is made of people who look mainly for *low-cost* and *convenience*.

For the entire interviewed base, an interesting relationship emerges: the degree of interest is inversely related to the degree of knowledge of the service. In particular it has been noticed that people who declare a low level of interest in these services are those who actually know least the main features and potential outcomes of these services, even though the interviewer deeply explained the meaning of each service.

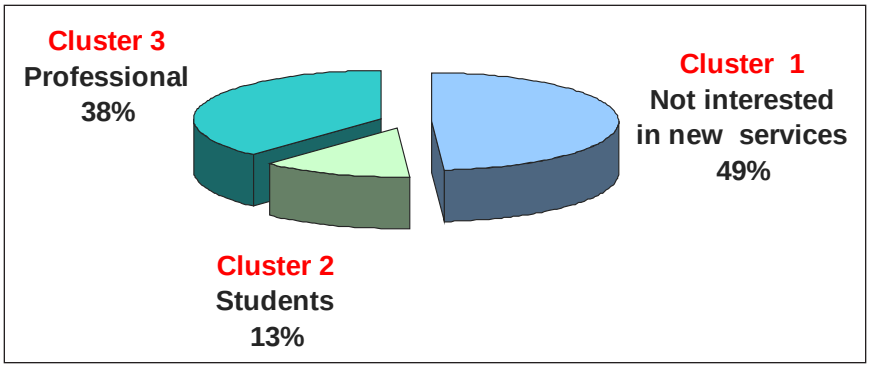
CONCLUSION

In this research, we attempt to identify valid factors that predict a user's adoption of 3G mobile multimedia services.

The findings show key characteristics and factors playing decisive roles in the development of strategies for the launch of multimedia mobile services.

The findings of this study have significant implications also in the perspective of research on mobile consumer behavior. Our study provides further evidence on the appropriateness of using the TAM model to measure the different dimensions of actual multimedia mobile usage and it

Figure 6. Main clusters of mobile users in the Italian market (base 1,000 Italian mobile users)



provides empirical evidence that PEU (perceived ease of use) and PU (perceived usefulness) are important factors that influence the user's adoption of 3G multimedia mobile services.

The findings of the study suggest important practical implications for businesses currently providing mobile multimedia services as well as those that are planning to do so. It is evident from this study that in order to influence adoption of 3G multimedia services, perceived ease of use (PEU) and perceived usefulness (PU) must be enhanced.

ACKNOWLEDGMENT

The authors wish to acknowledge Massimo Farioli for his cooperation in the data processing phase.

Chapter 1.16
A Proposed Framework for Mobile Services Adoption:
A Review of Existing Theories, Extensions, and Future Research Directions

Indrit Troshani
University of Adelaide, Australia

Sally Rao Hill
University of Adelaide, Australia

ABSTRACT

Mobile services are touted to create a significant spectrum of business opportunities. Acceptance of these services by users is, therefore, of paramount importance. Consequently, a deeper insight is required to better understand the underlying motivations leading users to adopting mobile services. Further, enhanced understanding would also help designing service improvements and appropriate adoption strategies. Most of the existing theoretical acceptance models available originate from organisational contexts. As mobile services bring additional functional dimensions, such as hedonic or experiential aspects, using extant models for predicting mobile services acceptance by individuals may be inadequate. The aim of this chapter is to explore and critically assess the use of existing acceptance theories in the light of evolving mobile services. Constructs affecting adoption behaviour are discussed and relevant extensions are made which culminate with a framework for mobile services adoption. Managerial implications are explored and future research directions are also identified.

INTRODUCTION

Mobile technologies and services are touted to create a significant spectrum of business opportunities. According to the International Telecommunications Union (ITU) mobile phone penetration rates have increased significantly in many countries in Northern Europe (e.g., Sweden—98.05%, Denmark—88.72%, Norway—90.89%) (Knutsen,

Constantiou, & Damsgaard, 2005). Similarly, Japan and Korea have consistently experienced very high diffusion rates of mobile devices and services (Carlsson, Hyvonen, Repo, & Walden, 2005; Funk, 2005). While experts predict that by 2010 online access via mobile channels is expected to reach 24% of homes in North America, 27% in Eastern Europe, and 33% in North-Western Europe (Hammond, 2001), the current penetration rate in many countries in the Western hemisphere and Asia-Pacific, including the U.S. and Australia lags behind the forerunners (Funk, 2005; Ishii, 2004; Massey, Khatri, & Ramesh, 2005). Given the difference between rapid growth rates in the adoption of mobile technologies and associated services in some countries and the relatively slow growth rates in others (Bina & Giaglis, 2005; Knutsen et al., 2005), it is important to identify the factors and predictors of further adoption and integrate them into a consolidated framework.

Mobile technology is enabled by the collective use of various communication infrastructure technologies and portable battery-powered devices. Examples of mobile devices include notebook computers, personal digital assistants (PDAs) and PocketPCs, mobile, "smart" and Web-enabled phones, and global positioning system (GPS) devices (Elliot & Phillips, 2004). There is a variety of communication infrastructure technologies that can enable these devices. Data networking technologies, such as GSM, GPRS, and 3G, are typically used for connecting mobile phones. WiFi (wireless fidelity) is used for connecting devices in a local area network (LAN). Mobile devices can be connected wirelessly to peripherals such as printers and headsets via the Bluetooth technology and virtual private networks (VPNs) enable secure access to private networks (Elliot & Phillips, 2004). Mobile devices are powered by mobile applications which deliver various services while enhancing flexibility, mobility, and efficiency for users within business and life domains. Despite the availability of technologically advanced mobile devices there is evidence that advanced mobile services which run on these have not been widely adopted (Carlsson et al., 2005; Khalifa & Cheng, 2002). The adoption of advanced mobile services is important for the mobile telecommunications industry because mobile services associated with technologically advanced devices constitute a massive source of potential revenue growth (Alahuhta, Ahola, & Hakala, 2005; Massey et al., 2005).

The adoption of advanced mobile technologies and services requires further research as most of the current technology acceptance models are based on research conducted in organisational contexts (Carlsson et al., 2005), and there has been only limited research from consumers' perspective (Lee, McGoldrick, Keeling, & Doherty, 2003). The features of mobile technologies and services, such as short message service (SMS), multimedia messaging service (MMS), e-mail, map, and location services, allow for single wireless devices, such as mobile phones, to be used seamlessly and pervasively across traditionally distinct spheres of life, such as work, home, or leisure, and with various levels of time commitment and self-ascribed roles (Dholakia & Dholakia, 2004). The interactions of these aspects are more intense than ever before (Knutsen et al., 2005). As mobile technologies and services add other functional dimensions, such as hedonic and/or experiential aspects (Kleijen, Wetzels, & de Ruyter, 2004; Mathwick, Malhotra, & Rigdon, 2001), applying extant theories outright to determine the acceptance and adoption by individual users may be questionable and inadequate (Knutsen et al., 2005).

Moreover, more research is called for in the adoption of mobile technologies because of the levels of complexity and diversity that may be encountered during their adoption. A number of factors contribute to this level of complexity and diversity. First, there is a strong relationship between the mobile devices and their users because the former always carries the identity of the latter (Chae & Kim, 2003). As a result,

spatial positioning and identification of users is easier in the mobile context than in the traditional innovation adoption (Figge, 2004). Second, most mobile devices have limited available resources including memory, processing power, and user interface, which have the potential to offset ubiquity benefits (Chae & Kim, 2003; Figge, 2004). Third, the lifecycle of mobile technologies is usually short, which increases adoption risks because new technologies become rapidly obsolete and may, therefore, need to be replaced by newer ones. During this process, a certain amount of consumer learning might be required before adopters can be confident and satisfied in using the mobile devices and services (Saaksjarvi, 2003). Again, this supports the argument that current models of technology acceptance may not be applied directly in predicting mobile adoption behaviour because they do not reflect the levels of complexity and diversity in the adoption of mobile technologies.

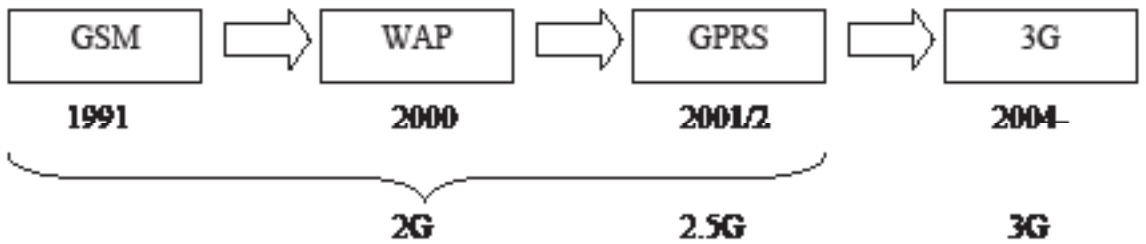
This chapter focuses on mobile phones and the associated services. Examples of mobile services include mobile e-mail, commercial SMS, and MMS services, downloads to portable devices, access to news through a mobile phone, mobile ticket reservations, mobile stock trading, as well other customised services which may be made available by mobile phone operators (Bina & Giaglis, 2005). Research shows that ownership of technologically advanced mobile phones is a main driver for advanced mobile services (Carlsson et al., 2005). Therefore, the adoption of mobile services should also be considered in the context and the technologies which enable them.

The aim of this chapter is to extend the existing models and to propose an integrated conceptual and parsimonious framework which explains adoption behaviour of users of mobile technologies and services. To accomplish this, we first provide an overview of recent developments of mobile technologies and services. Then, a critical assessment of existing acceptance models is made. Next, acceptance constructs and their relevance to mobile technologies and services are discussed. These constructs are then integrated into a new framework about mobile services adoption. In the last section, the implications of this model and future research directions are also discussed.

OVERVIEW OF MOBILE TECHNOLOGY EVOLUTION

In this section, an overview of the evolution of mobile phone technologies is provided. The recognition the evolution of these technologies is important because it puts the adoption constructs discussed later in the appropriate context. The diagram in Figure 1 summarises the evolution of the technologies.

Figure 1. Evolution of wireless technologies (Source: Carlsson et al., 2005)



Second Generation Wireless Devices

The second generation of wireless devices (2G) introduced the digitisation of mobile communication and encompasses several standards which incrementally introduced new services and improved existing ones. It was a big leap forward from the first generation wireless communication (1G) which used analog standards and was characterised by poor quality and narrow bandwidth which resulted in limited adoption by both businesses and individuals (Elliot & Phillips, 2004). The commonly used standards by 2G are the Global System for Mobile Communications, the Wireless Applications Protocol, and the General Packet Radio Service. These are explained in more detail in the following sections.

Global System for Mobile Communication

Launched in the early 1990s, the Global System for Mobile Communications (GSM) constitutes the world's fastest growing and most popular mobile telephony. Available through over 500 networks and serving almost a billion customers in 195 countries, GSM has been expanding exponentially (UMTS, 2003). Most countries, including underdeveloped and developing or even countries with a very low population density have at least two GSM network operators (Rossotto, Kerf, & Rohlfs, 2000). This has increased product and service offerings and competitiveness which has boosted GSM popularity even further.

One of the key advantages of the GSM technology is that it unified a range of different mobile communication standards into a single standard which constitutes a complete and open network architecture. This allows GSM-compatible mobile devices to be connected to any GSM network, therefore, enhancing interoperability. Further, GSM uses digital encoding which encrypts communications between a mobile phone and its base station, which makes interception more difficult. This results in improved security (Elliot & Phillips, 2004).

Another feature of the GSM technology is the automatic country-to-country communication, also known as global roaming. Because international travel for both business and pleasure has increased in recent years, roaming between mobile networks has become valuable as it generates as much as 15% of mobile operator's average revenue per user (ARPU) (UMTS, 2003). The subscriber identity module (SIM) card is another aspect of the GSM technology which is central to its popularity. The SIM card allows operators to manage information about their customers, including customer profile and billing, security access and authentication, virus intrusion and downloading capabilities (UMTS, 2003).

In addition to features such as caller ID, call forwarding, and call waiting, SMS emerged as the first unique mobile service and became the most popular mobile service after 1995 when adopters began using mobiles to send and receive limited amount of data in the form of short messages (Carlsson et al., 2005). While SMS later became the foundational platform for a variety of other services, it is considered to be cumbersome by many users because in addition to memorise service codes, users are also required to type text using the keypad of the mobile device (Carlsson et al., 2005).

Wireless Application Protocol

The Wireless Application Protocol (WAP) was introduced with the aim of providing advanced telephony and data access from the Internet using mobile terminals such as mobile phones, PDAs, smart phone, and other portable handheld devices (van Steenderen, 2002). With WAP, mobile devices can access Web sites specifically designed and built for them. WAP was, therefore, expected to provide the opportunity for connecting two of the fastest growing sectors of the telecommunications industry, namely, the Internet and mobile

communications. As a matter of fact, the hype generated by WAP reached such dizzying heights that from January to August 2000, the number of WAP-compatible Web pages increased from almost zero to 4.4 million (Teo & Pok, 2003).

The benefits of WAP were supposed to extend to several industries ranging from mobile operators, developers of WAP applications, manufacturers of mobile devices, and consumers in terms of various services, including banking, ticket reservations, entertainments, voice and fax mail notifications (Klasen, 2002; van Steenderen, 2002). Nevertheless, except for NTT DoCoMo's i-mode successful demonstration of mobile Internet, WAP has turned out to be a major disappointment with early adopters and other enthusiasts experiencing cognitive dissonance due to the relative oversell (Carlsson et al., 2005; Ratliff, 2002; Teo & Pok, 2003; Xylomenos & Polyzos, 2001).

Other challenges have also adversely affected widespread diffusion of WAP. Narrow bandwidth, low storage memory, and small screen limitations have resulted in slow communications; abridged Internet access has resulted in mediocre interfaces and almost no graphics. This has considerably limited Web site effectiveness (Klasen, 2002). By the end of 2000, only 12 million Europeans had WAP-compatible mobile devices, and of these, only 6% regularly used WAP functionality (Robins, 2003). Worldwide, only 10-15% of whom own WAP-compatible mobile devices would ever use WAP services, suggesting that "WAP had no future" (Klasen, 2002, p. 196). Nonetheless, the introduction of WAP constitutes a major step forward as it showed that Internet browsing is possible in mobile devices in general and phones in particular (Carlsson et al., 2005).

General Packet Radio Service

Simply known as the GPRS, the General Packet Radio Service constitutes an improvement over the GSM technology. GPRS uses packet-based data transfer mechanisms to provide continuous Internet accessibility (Elliot & Phillips, 2004; Hart & Hannan, 2004). With GPRS, users are not required to stay connected all the time in order to use a service. As a result, they are not charged on the basis of the connection time, rather, on the basis of the amount of downloaded data (Carlsson et al., 2005). Overall, GPRS is more efficient and cheaper than GSM, and yet, less widespread among users. Advancements associated with GPRS include the introduction of cameras, colour screens, multimedia messaging service (MMS), and video streaming (Carlsson et al., 2005). Because GPRS enhances 2G services, it is often referred to as the 2.5G technology (Elliot & Phillips, 2004).

Third Generation Wireless Devices

3G represents the next generation of mobile communication technologies, and it makes considerable improvements over its predecessors. These improvements include broad bandwidth which results in higher connection speeds, variety of multimedia capabilities and improved screen display, enhanced security features, and increased storage capacity (Elliot & Phillips, 2004). These enhancements enable users to receive digital photographs, moving video images, high quality sound in their mobile devices, and full unabridged e-mail and Internet access (Elliot & Phillips, 2004). Corporate users are also able to connect remotely to office computers and networks in order to access and download files quickly and easily (Robins, 2003). Because 3G technology mainly improves and enhances many existing services, it is considered to be an evolution rather than a revolution over the previous generation (Carlsson et al., 2005).

3G ensures that anybody, anywhere can access the same services (Grundström & Wilkinson, 2004). Further, 3G aims at integrating both the business and the social domains of the user's life which is the reason why 3G terminals are also referred to as "lifestyle portals" (Elliot & Phillips,

2004, p. 7). Another feature of the 3G technology is its capability to provide location-based services (LBS) which could support health, transport, entertainment, data mining, and so forth (Casal, Burgelman, & Bohlin, 2004; UMTS, 2003). There is evidence that there is demand for such services which constitutes the main economic incentive for the development of the 3G technology (Alahuhta et al., 2005; Repo, Hyvonen, Pantzar, & Timonen, 2004).

A CRITICAL REVIEW OF THEORETICAL MODELS OF TECHNOLOGY ACCEPTANCE

A review of technology acceptance literature revealed many competing theoretical models, each with different focus and tested in different contexts. A significant amount of research effort has been put into building theories to examine how and why individuals adopt new information technologies and predict their level of adoption and acceptance. While one stream of research focuses on individual acceptance of technology (Compeau & Higgins, 1995; Davis, Bagozzi, & Warshaw, 1989), other streams have focused on implementation success at the organizational level (Leonard-Barton & Deschamps, 1988).

Many of the previously empirically researched models have been drawn from social psychology, for example, theory of reasoned action (TRA), motivational model, theory of planned behaviour (TPB), and sociology, for example, social cognitive theory (SCT) and innovation diffusion theory (IDT). Others specifically apply to technology adoption, for example, technology acceptance model (TAM). While each of these models made unique contributions to the literature on technology acceptance and adoption, most of these theoretical models theorise behaviour intention and/or usage as the key dependent variable in explaining acceptance of information technology because behavioural intentions are motivational factors that capture how hard people are willing to try to perform a behaviour (Ajzen, 1991). For example, TPB suggests that behavioural intention is the most influential predictor of behaviour; after all, a person does what s/he intends to do. In a meta-analysis of 87 studies, an average correlation of 0.53 was reported between intentions and behaviour (Sheppard, Hartwick, & Warshaw, 1988). As mobile services and underlying technologies are emerging information technologies, it is appropriate to consider this as the point of departure and use it to form the basis of a theoretical framework in mobile services and technology acceptance and adoption. The models that have been most frequently quoted in the technology acceptance and adoption literature are discussed next.

Theory of Reasoned Action (TRA)

Theory of reasoned action models are considered to be the most systematic and extensively applied approaches to attitude and behaviour research. According to TRA, the proximal determinant of a behaviour is a behavioural intention, which, in turn, is determined by attitude. These models propose that an individual's actual behaviour is determined by the person's intention to perform the behaviour, and this intention is influenced jointly by the individual's attitude and subjective norm. Attitude is defined as "a learned predisposition to respond in a consistently favourable or unfavourable manner with respect to a given object" (Fishbein & Ajzen, 1975, p. 6). A person's attitude towards a behaviour is largely determined by salient beliefs about the consequences of that behaviour and the evaluation of the desirability of the consequences (Fishbein & Ajzen, 1975). Subjective norm is defined as "the person's perception that most people who are important to him think he should or should not perform the behaviour in question" (Dillon & Morris, 1996). In brief, TRA asserts that attitude and subjective norm and their relative weights directly influence behavioural intention.

Theory of Planned Behaviour (TPB) and Decomposed Theory of Planned Behaviour

TPB, which generalizes TRA by adding a third construct—perceived behavioural control (Ajzen, 1991)—has been one of the most influential theories in explaining and predicting behaviour, and it has been shown to predict a wide range of behaviours (Sheppard et al., 1988). TPB asserts that the actual behaviour is determined directly both by behavioural intention and perceived behavioural control. Behavioural intention is formed by one's attitude, subjective norm, and perceived behavioural control (Ajzen, 1991). Further, a decomposed TPB includes constructs such as relative advantage, compatibility, influence of significant others, and risk from the innovation diffusion literature, and decomposing the three perceptions in TPB into a variety of specific belief dimensions. This model offers several advantages over TPB and is considered more complete and management-relevant by focusing on specific factors that may influence adoption and usage (Teo & Pok, 2003).

Technology Acceptance Model (TAM)

TAM can be seen as an adaptation of the theory of reasoned action (TRA) and was developed to predict and explain individual system use in the workplace (Davis, 1989). This model further suggests that two beliefs—perceived usefulness and perceived ease of use—are instrumental in explaining the user's intentions of using a system. Perceived usefulness refers to the degree to which "a person believes that use of the system will enhance his or her performance" whereas perceived ease of use is the degree to which "a person believes that using the system will be free of effort". Simply put, a technology that is easy to use and is useful will lead to a positive attitude and intention towards using the technology.

The main advantage of this model over others is that the two related beliefs can generalize across different settings. Thus, some argue that it is the most robust, parsimonious, and influential model in explaining information technology adoption behaviour (Elliot & Loebbecke, 2000; Teo & Pok, 2003; Venkatesh, Morris, Davis, & Davis, 2003). Indeed, since its development, it has received extensive empirical support through validations, applications, and replications for its prediction power (Taylor & Todd, 1995, 1995a; Venkatesh & Morris, 2000a). A number of modified TAM models were proposed to suit new technologies including Internet and intranet (Agarwal & Prasad, 1998; Chau, 1996; Chau & Hu, 2001; Horton, Buck, Waterson, & Clegg, 2001). For example, TAM has been used to predict Internet purchasing behaviour (Gefen, Karahanna, & Straub, 2003; Kaufaris, 2002).

A major theoretical limitation of TAM is the "exclusion of the possibility of influence from institutional, social, and personal control factors" (Elliot & Loebbecke, 2000, p. 49). Thus the suitability of the model for predicting general individual acceptance needs to be re-assessed as the main TAM constructs do not fully reflect the specific influences of technological and usage-context factors that may alter user acceptance (King, Gurbaxani, Kraemer, McFarlan, Raman, & Yap, 1994; Taylor & Todd, 1995). In response to this, a number of modifications and changes to the original TAM models have been made. The most prominent of these is the unified theory of acceptance and use of technology (UTAUT), a unified model that integrates constructs across eight models (Venkatesh et al., 2003). UTAUT provides a refined view of how the determinants of intention and behaviour evolve over time and assumes that there are three direct determinants of intention to use (performance expectancy, effort expectancy, and social influence) and two direct determinants of usage behaviour (intention and facilitating conditions). However, both TAM and UTAUT have received criticisms with

the fundamental one being about the problems in applying these beyond the workplace and/or organisation for which originally created (Carlsson et al., 2005).

Motivational Theories

Motivation theories are rooted in psychological research to understand individuals' acceptance of information technology (Davis, Bagozzi, & Warshaw, 1992; Igbaria, Parasuraman, & Baroudi, 1996). These theories often distinguished extrinsic and intrinsic motivation. While extrinsic motivation refers to the performance of an activity in helping achieve valued outcomes, intrinsic motivation puts emphasis on the process of performing an activity (Calder & Staw, 1975; Deci & Ryan, 1985). For example, perceived usefulness is an extrinsic source of motivation (Davis et al., 1992) while perceived enjoyment (Davis et al., 1992), perceived fun (Igbaria et al., 1996), and perceived playfulness (Moon & Kim, 2001) can be considered intrinsic sources of motivation. Both sources of motivation affect usage intention and actual usage. Therefore, in addition to ease of use and usefulness, intrinsic motivators, such as playfulness, will also play an important role in increasing usability in a usage environment in which information technology applications are both used for work and play (Moon & Kim, 2001).

Innovation Diffusion Theory

The innovation diffusion theory is concerned with how innovations spread and consists of two closely related processes: the diffusion process and adoption process (Rogers, 1995). Diffusion is a macro process concerned with the spread of an innovation from its source to the public whereas the adoption process is a micro process that is focused on the stages individuals go through when deciding to accept or reject an innovation. Key elements in the entire process are the innovation's perceived characteristics, the individual's attitude and beliefs, and the communication received by individuals from their social environment. In relation to the factors pertaining to innovation, factors such as, relative advantage, complexity, trialability, observability, and compatibility, were considered important in influencing individual's acceptance of the innovation (Rogers, 1995).

TOWARDS AN ACCEPTANCE MODEL FOR MOBILE SERVICES

This section develops an acceptance model for mobile technology and services that may be empirically tested. This development begins with identifying the latent constructs in extant technology adoption literature. However, mobile services differ from traditional systems in that mobile services are ubiquitous, portable, and can be used to receive and disseminate personalised and localised information (Siau, Lim, & Shen, 2001; Teo & Pok, 2003). Thus, the models examined in the previous section and the constructs included in these models may not be applicable to mobile services adoption. In particular, we discuss the various antecedents of attitude towards mobile services and develop a new model based on the widely used TAM model to predict adoption of new mobile services.

User Predisposition

User predisposition refers to the internal factors of an individual user of mobile services. Personal differences strongly influence adoption. There is evidence that successful acceptance of innovations depends as much on individual adopter differences as on the innovation itself. Indeed, individual differences help identify segments of adopters who are more likely to adopt technology innovations than others, which in turn, helps providers address adopter needs more closely (Massey et al., 2005). Diffusion resources can also be used

more effectively and efficiently (Agarwal & Prasad, 1998). Early adopters, for example, can then act as opinion leaders or change agents to facilitate the diffusion of the technology further (Rogers, 1995). There are several dimensions used to capture individual differences, including personal innovativeness, perceived costs, demographic factors, psychographic profiles, and personality traits (Dabholkar & Bagozzi, 2002). In this chapter, we define user predisposition as the collection of factors including the individual's prior knowledge and experience of existing mobile services, compatibility, behavioural control, personal innovativeness, perceived enjoyment, and price sensitivity.

First, *prior knowledge* is essential for the comprehension of the technology and related services. According to Rogers (1995), knowledge occurs when a potential adopter learns about the existence of an innovation and gains some understanding concerning its functionality. Like other technologies, the mobile technology is comprised of both the hardware (i.e., the physical mobile device) and software domains (i.e., the applications consisting of the instructions to use the hardware as well as other information aspects) (Rogers, 1995). Thus knowledge from both hardware and software domains might be required for complete comprehension (Moreau, Lehmann, & Markman, 2001; Saaksjarvi, 2003). Prior knowledge consists of two components, namely, familiarity and expertise. For instance, the former constitutes the number of mobile services-related experiences accumulated by consumers over time, which includes exposure to advertising, information search, interaction with salespersons, and so on. The latter represents the ability to use the mobile services, and it includes beliefs about service attributes (i.e., cognitive structures) as well as decision rules for acting on those beliefs (i.e., cognitive processes) (Alba & Hutchinson, 1987). In any case, familiarity alone cannot capture the complexity of consumer knowledge (Alba & Hutchinson, 1987), which suggests the learning is required (Saaksjarvi, 2003).

With learning, consumers use the "familiar" component of existing knowledge as a means to understand and comprehend new phenomena in the innovation which is being adopted (Roehm & Sternthal, 2001). Specifically, existing knowledge in general and analogical learning in particular have been shown to be powerful and highly persuasive communication devices in acquiring in-depth understanding of innovation benefits and functionality (Moreau et al., 2001; Roehm & Sternthal, 2001; Yamauchi & Markman, 2000). An analogy compares and contrasts a known base innovation to an unknown target innovation. The base and the target share structural attributes, but are different in terms of surface attributes. A cellular phone versus a personal digital assistant (PDA) versus a "smart phone" are good examples. Research shows that "a message containing an analogy is better comprehended and is more persuasive when the recipient has expertise with regard to the base product [innovation]." (Roehm & Sternthal, 2001, p. 269). However, expertise alone is insufficient to ensure analogy persuasiveness. Substantial resources, training/usage instructions, and a positive mood are also required to facilitate learning (Roehm & Sternthal, 2001). However, while knowledge is important, by itself, it has limited usefulness, and therefore, "knowledge alone cannot determine the basis for adoption" (Rogers, 1995, p. 167) of a technology or service.

Adopters' previous positive or negative *experiences* with a technology or service can have a significant impact on their perceptions and attitudes towards that technology (Lee et al., 2003; Taylor & Todd, 1995a). Specifically, experience may influence adopters in forming positive or negative evaluations concerning innovations, which can boost or impair adoption of mobile technologies and services. Because of their greater clarity and certainty, direct prior experiences are likely to have a stronger impact on perceptions and attitudes towards usage than indirect or incomplete evidence (i.e., pre-trial) (Knutsen et al., 2005; Lee et al., 2003).

The second variable within the user predisposition construct is *compatibility*. Rogers (1995) defines compatibility as the degree to which an innovation is perceived to be consistent with existing values of potential adopters. In general, high incompatibility will adversely affect potential adopters of an innovation, which decreases the likelihood of adoption (Saaksjarvi, 2003). In contrast, high compatibility is likely to increase adoption propensity. In the context of wireless devices, lifestyle compatibility is the extent to which adopters believe mobile devices and services can be integrated into their daily lives. For example, adopters' lifestyle in terms of degree of mobility is likely to have a strong impact on their decision to adopt the technology (Pagani, 2004; Teo & Pok, 2003). For example, a person who leads a busy lifestyle, and is employed in an information-intensive job, and is always on the move is more likely to adopt a wireless device and its associated services compared to a person who leads a sedentary lifestyle.

Third, perceived *behavioural control*, a dynamic and socio-cognitive concept, has attracted a lot of attention in adoption literature. Earlier work by Ajzen (1991) considered it as a uni-dimensional variable. More recent empirical findings suggest that perceived behavioural control has two distinct components: self-efficacy, which is an individual's judgement of their capability to perform a behaviour, and controllability, which constitutes an individual's beliefs if they have the necessary resources and opportunities to adopt the innovation. It denotes a subjective judgment of the degree of control over the performance of a behaviour not the perceived likelihood that performing the behaviour will produce a given outcome (Ajzen, 1991). In the context of mobile service adoption, perceived behavioural control refers to the individual perception of how easy or difficult it is to get mobile services.

Fourth, *personal innovativeness* is the willingness of an individual to try out and embrace new technologies and their related services for accomplishing specific goals. Also known as technology readiness, personal innovativeness embodies the risk-taking propensity which exists in certain individuals and not in others (Agarwal & Prasad, 1998; Massey et al., 2005; Parasuraman, 2000). This definition helps segment potential adopters into what Rogers (1995) characterises as innovators, early adopters, early and late majority adopters, and laggards. Personal innovativeness represents a confluence of technology-related beliefs which jointly determine an individual's predisposition to adopt mobile devices and related services. The adoption of any innovation in general, and of innovative mobile phones and services in particular is inherently associated with greater risk (Kirton, 1976). Therefore, given the same level of beliefs and perceptions about an innovation, individuals with higher personal innovativeness are more likely to develop positive attitudes towards adopting it than less innovative individuals (Agarwal & Prasad, 1998).

Fifth, *perceived enjoyment* refers to the degree to which using an innovation is perceived to be enjoyable in its own right and is considered to be an intrinsic source of motivation (Al-Gahtani & King, 1999). Because the market for mobile innovations and services is comprised of both corporate users and consumers, factors focusing on perceived enjoyment constitute an important consideration (Carlsson et al., 2005; Pagani, 2004). That is, adopters use an innovation for the pleasure or enjoyment its adoption might bring and, therefore, serve as an end unto itself. Further, intrinsic enjoyment operates outside valued outcomes or immediate material needs (i.e., extrinsic motivations), such as enhanced job performance, increased pay, and so forth (Mathwick et al., 2001; Moon & Kim, 2001). Most research on enjoyment is based on the "flow theory" according to which flow represents "the holistic sensation that people feel when they act with total involvement" (Csikszentmihalyi, 1975). In a "flow state" individuals interact more voluntarily with innovations within their specific context, which determines their subjective expe-

riences (Csikszentmihalyi, 1975). Consequently, individuals who have a more positive enjoyment experience with an innovation are likely to have stronger adoption intentions than those who do not (Moon & Kim, 2001).

That is, intrinsic enjoyment can positively affect the adoption and use of innovative mobile services, and is therefore, a significant determinant of intention and attitude towards adoption (Kaufaris, 2002; Novak, Hoffman, & Yung, 2000). Further, upon adoption, individuals are more likely to use the mobile services that offer enjoyment more extensively than those which do not. As a consequence, perceived enjoyment is also seen to have a significant effect beyond perceived usefulness (Davis et al., 1989a). However, the complexity of a mobile innovation or service has a negative effect on perceived enjoyment, suggesting that the potential impact of enjoyment may not be fully realised (Igbaria et al., 1996).

The final variable that needs to be added to the existing technology adoption models is *price sensitivity*. In the original technology acceptance models, the costs of adopting an innovation were not considered to be a relevant construct because the actual users did not have to pay for the technology. In an organisational setting, the cost would be incurred by the organisation. However, in the context of individual private adoption, cost becomes a relevant factor. There is evidence showing that perceived financial resources required to adopt mobile technologies and services constitute a significant determinant of behavioural intention (Kleijen et al., 2004; Lin & Wang, 2005). However, evidence also shows that adopters of mobile devices and services also attempt to assess the value of adoption by comparing perceived costs against the benefits (Pagani, 2004). Perceived costs are directly related to income and socioeconomic status of potential adopters which are recognised to have a strong impact on technology adoption and diffusion (Lu, Yu, Liu, & Yao, 2003). For example, in Europe individuals earning income beyond certain levels were found to have a high propensity to embrace mobile technologies, such as WAP mobile phones, handheld computers, and so forth (Crawford, 2002). Similarly, there's evidence that in fast growing economies, individuals with higher income spend more on mobile devices (Lu et al., 2003).

Perceived Usefulness

Perceived usefulness is "the degree to which a person believes that using a particular system would enhance his or her job performance" (Davis, 1989, p. 320). Perceived usefulness is also known as performance expectancy (Venkatesh et al., 2003). An innovation is believed to be of high usefulness when a potential adopter believes that there is a direct relationship between use on the one hand and productivity, performance, effectiveness, or satisfaction on the other (Lu et al., 2003).

Usefulness recognition is important because it has been found to have a strong direct effect on the intention of adopters to use the innovation (Adams, Nelson, & Todd, 1992; Davis, 1989). In addition, potential adopters assess the consequences of their adoption behaviour and innovation usage in terms of the ongoing desirability of usefulness (Chau, 1996; Venkatesh & Davis, 2000). Although an innovation might provide at least some degree of usefulness, a potential reason not to adopt exists when adopters fail to see the "need" to adopt (Zeithaml & Gilly, 1987). Adopters may not be able to recognise their needs until they become aware of the innovation or its consequences (Rogers, 1995). Need recognition is, therefore, likely to drive potential adopters to educate themselves in order to be able to utilise the innovation fully before being able to recognise its usefulness. This in turn is likely to lead to a faster rate of adoption (Rogers, 1995; Saaksjarvi, 2003).

Perceived usefulness can be split into two parts. Near-term usefulness is perceived to have an impact on the near-term job fit, such as job performance or satisfaction (Thompson, Higgins, & Howell, 1994). Long-term usefulness is

perceived to enhance the future consequences of adoption including career prospects, opportunity for preferred job assignments, or social status of adopters (Chau, 1996; Thompson et al., 1994). Evidence shows that even though perceived near-term usefulness has the most significant impact on the behavioural intention to adopt an innovation, perceived long-term usefulness also exerts a positive, yet lesser impact (Chau, 1996; Jiang, Hsu, Klein, & Lin, 2000).

In the case of mobile technology and services, perceived usefulness is defined as the degree to which the mobile technology and services provide benefits to individuals in every day situations (Knutsen et al., 2005). The range and type of service offerings as well as the compatibility of the user's existing computing devices influence perceived usefulness (Pagani, 2004). In addition, Pagani (2004) also finds that usefulness emerges as the strongest determinant in the adoption of three generation mobile services which is consistent finds of research concerning the adoption of other innovations (Venkatesh et al., 2003).

Perceived Ease of Use

Perceived ease of use is the "degree to which a person believes that using a particular system would be free of effort" (Davis, 1989, p. 320). Other constructs that capture the notion of perceived ease of use are complexity and effort expectancy (Rogers, 1995; Venkatesh et al., 2003). Perceived ease of use may contribute towards performance, and therefore, near-term perceived usefulness. In addition, lack of it can cause frustration, and therefore, impair adoption of innovations. Nevertheless, "no amount of EOU [ease of use] will compensate for low usefulness" (Keil, Beranek, & Konsynski, 1995, p. 89).

In the mobile setting, perceived ease of use represents the degree to which individuals associate freedom of difficulty with the use of mobile technology and services in everyday usage (Knutsen et al., 2005). For example, there is evidence in the media that using certain services on a mobile device can be quite tedious, especially when browsing Internet-like interfaces on mobile devices is required (Teo & Pok, 2003). Together with relatively small screen sizes and associated miniaturized keypads, the overall usage experience may be adversely affected. This suggests that input and output devices are likely to influence perceived ease of use (Pagani, 2004). In addition, user-friendly and usable intuitive man-machine interfaces, including clear and visible steps, suitable content and graphical layouts, help functions, clear commands, symbols, and meaningful error messages are likely to influence adoption as well (Condos, James, Every, & Simpson, 2002). Further, Pagani (2004) argues the mobile system response time affects perceived ease of use suggesting that mobile bandwidth is important as well.

Social Influences

Social influence constitutes the degree to which individuals perceive that important or significant others believe they should use an innovation (Venkatesh et al., 2003). Venkatesh et al. (2003) believe that the social influence constructs may only become significant drivers on intention to adopt when users adopt an innovation in order to comply mandatory requirements. In these circumstances, social influence seems to be significant in the early phases of adoption and its effect decreases with sustained usage (Venkatesh & Davis, 2000). Conversely, in voluntary settings, social influence appears to have an impact on perceptions about the innovation (Venkatesh et al., 2003). Social influence is related to three similar constructs, namely, subjective and social norms, and image.

In Taylor and Todd's study (1995), subjective norms are defined to include the influence of other people's opinions otherwise known as reference groups. These include peers, friends, superiors, computer, and technology experts. Subjective

norms have a greater impact during the initial adoption phase when potential adopters have little or no experience or when the adoption behaviour is new (Thompson et al., 1994). Research shows that pressure from reference groups to adopt an innovation is effective because it contributes to reducing perceived risk associated with adoption (Teo & Pok, 2003).

Social factors constitute another construct of social influence. Social factors represent cues individuals receive from members of their social structure which prompt them to behave in certain ways (Thompson, Higgins, & Howell, 1991). For example, in Japan, teenagers regard smart phones as fashion items (Lu et al., 2003). Further, there is evidence that unique communications patterns determined by key social and cultural factors, such as group-oriented nationality, have positively affected adoption practices of using the Internet via mobile phones in East Asia (Ishii, 2004).

A third critical construct related to social influence is image. The adoption of an innovation can be seen to enhance one's status or image in their social system. For certain adopters a mobile device may be more of a lifestyle than a necessity (Bina & Giaglis, 2005; Teo & Pok, 2003). For example, early adopters of mobile computing devices might be image-conscious users who wish to be seen as trend-setters or technology savvy enthusiasts.

Facilitating Conditions

Facilitating conditions refer to external controls and catalysts in the adoption environment which aim at facilitating adoption and diffusion of new technologies (Terry, 1993). Facilitating conditions are important because they are considered to be direct usage antecedents, and are therefore, likely to make adoption behaviour less difficult by removing any obstacles to adoption and sustained usage (Thompson et al., 1994; Venkatesh et al., 2003). These conditions can be provided by both governments and mobile operators. For example, governments or the representative agencies can act as facilitators by bringing together the telecommunication industry, academia, and research community. Government agencies can also set up protocol standardization policies and regulations favouring the future growth of mobile communication systems (Lu et al., 2003). Likewise, mobile operators can encourage adoption by mass advertising campaigns and active promotion aimed at increasing awareness about mobile devices and related services (Teo & Pok, 2003). Further, promoting and enforcing appropriate interconnection agreements and adequate regulatory mechanisms among mobile operators help adopters of mobile devices take advantage of roaming services and consequently be conducive to adoption (Rossotto et al., 2000).

Facilitating conditions also capture the existence of a trusting environment that is external to the mobile operator's control. A trusting environment constitutes an important factor in the adoption of mobile technologies and services. It determines the user's expectations from the relationship with their service providers, and it increases their perceived certainty concerning the provider's expected behaviour. Generally, trust is essential in all economic activities where undesirable opportunistic behaviour is likely to occur (Gefen et al., 2003). However, trust becomes vital in a mobile environment, where situational factors such as uncertainty or risk and information asymmetry are present (Ba & Pavlou, 2002). On the one hand, adopters of mobile technology are unable to judge the trustworthiness of service providers, and on the other, the latter can also easily take advantage of the former by engaging in harmful opportunistic behaviours. For example, service providers can sell or share the transactional information of its users or their personal information.

There are two key elements in a trusting environment, namely, security and privacy (Lu et al., 2003). In a wireless environment, security encompasses confidentiality, authentication, and message integrity. Because mobile devices

have limited computing resources and wireless transmissions are more susceptible to hacker attacks, security vulnerabilities can have serious consequences (Galanxhi-Janaqi & Nah, 2004; Lu et al., 2003). There are several remedies against the dangers of insecurity, for example, public key infrastructure and certificate authority which use public key cryptography to encrypt and decrypt mobile transmissions and authenticate users.

Ironically, the same information practices which provide value to both users and providers of mobile technology and services also cause privacy concerns. Some of these concerns include: the type of information that can be collected about users and the ways in which it will be protected; the entities that can access this information and their accountability; and the ways in which the information will be used (Galanxhi-Janaqi & Nah, 2004). In mobile adoption research the trust environment has been encapsulated in a construct called perceived credibility (Lin & Wang, 2005; Wang, Wang, Lin, & Tang, 2003). Evidence shows that there is a "significant direct relationship between perceived credibility and behavioural intention" (Lin & Wang, 2005, p. 410) to use mobile services.

Moderating Variables

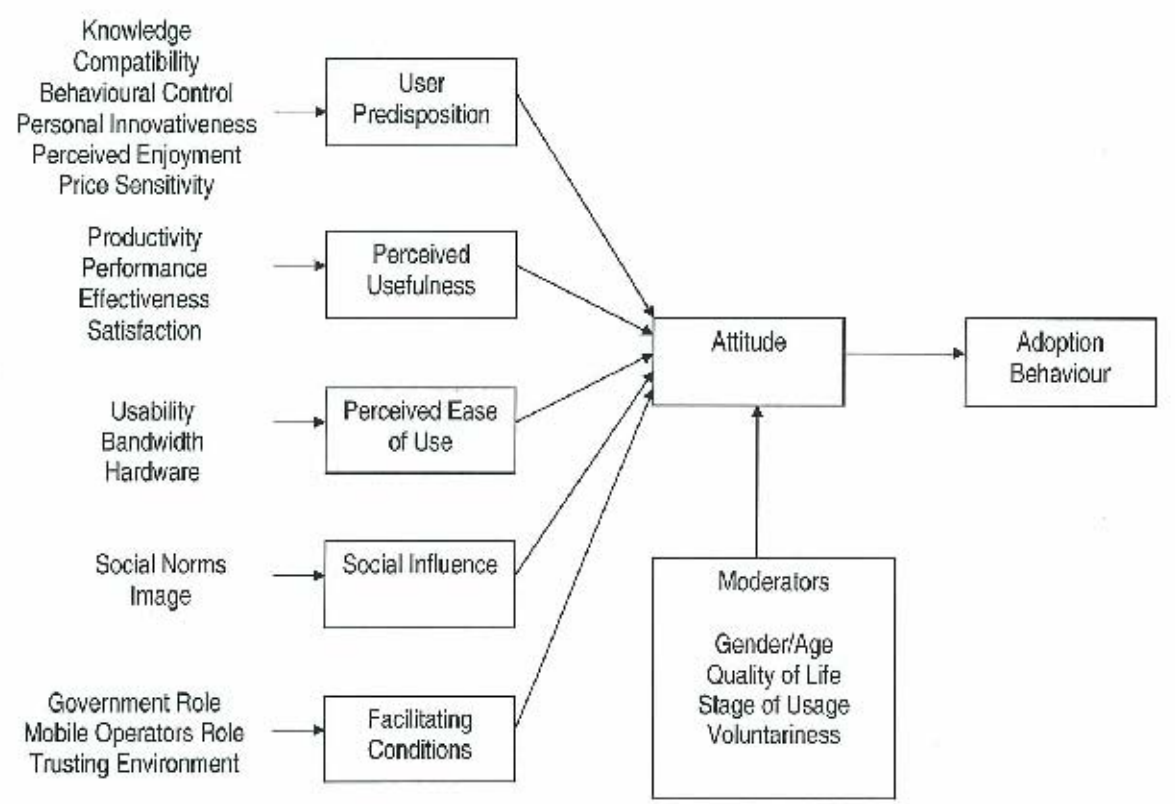
Evidence shows that gender and age might influence the adoption of technology and related services due to their moderating effects on other constructs (Venkatesh et al., 2003). In general, men tend to exhibit task-oriented attitudes suggesting that usefulness expectations might be more accentuated in men than women (Minton & Scheneider, 1980). This is particularly the case for younger men (Venkatesh & Morris, 2000a). On the other hand, ease of use expectations are more salient for women and older adopters (Bozionelos, 1996). Further, women are predisposed to be more sensitive to the opinions of members of their social structure. As a result women are more likely to be affected by social influence factors when deciding to adopt new mobile technologies and services (Venkatesh & Morris, 2000a). Similarly, because affiliation needs increase with age (Rhodes, 1983), older adopters are more likely to be affected by social influence.

Quality of life of potential adopters is another moderating variable which is likely to affect the adoption of mobile devices and services. "Quality of life" is an established social sciences notion which represents "a global assessment of a person's life satisfaction according to his chosen criteria" (Diener & Suh, 1997; Shin & Johnson, 1978). There is evidence which indicates that mobile technology and services have enhanced the perceived quality of social and work life of adopters (Jarvenpaa, Lang, Takeda, & Tuunainen, 2003). Bina and Giaglis (2005) present evidence that the reverse is also true. They indicate that adopters who are satisfied with specific life domains exhibit favourable attitudes towards the adoption of specific mobile services (Bina & Giaglis, 2005).

Further, evidence also shows that stage of use and voluntariness of usage have moderating effects on adoption attitudes through various constructs. For example, perceived ease of use is significant during the initial period of usage when process-related issues constitute obstacles to be overcome (Venkatesh et al., 2003). Perceived ease of use, however, becomes insignificant during periods of extended usage (Agarwal & Prasad, 1998; Davis et al., 1989a; Thompson et al., 1994). Similarly, ease of use has a significant positive effect on attitude toward use in both voluntary and mandatory usage contexts (Al-Gahtani & King, 1999; Keil et al., 1995; Venkatesh & Davis, 2000).

To summarise the constructs discussed in this section, Figure 2 portrays a proposed model of acceptance of mobile services. The implications of this model are discussed next.

Figure 2. Proposed model of acceptance of mobile services



PROPOSED METHOD

In order to validate the model discussed in the previous section, we propose a two-stage research design, consisting of both qualitative and quantitative approaches.

Qualitative Stage

This stage is the first round of the fieldwork data collection. Data collection at this stage would involve conducting face-to-face in-depth interviews in order to study the perceptions of all stakeholders who contribute directly or indirectly to providing mobile services. Stakeholder targets include mobile operators or carriers, industry and government associations, user groups, mobile application developers, content providers, aggregators, as well as manufacturers of mobile devices. The aim of these interviews is to gather an in-depth understanding of the perceptions and perspectives of all stakeholders involved in the adoption and diffusion of mobile services.

To ensure validity in this research design, several tactics may be used. Construct validity would be addressed by using the multiple sources of evidence as noted previously. The issue of internal validity would be considered by using the techniques of pattern matching the data to a predicted pattern of variables, and formulating rival explanations. In addition, an interview protocol should be developed to guide the data collection. A single pilot case study is recommended to be used in order to refine data collection procedures and improve conceptualisation of the model prior to finalising

the set of theoretical propositions developed from the literature.

The second round of the qualitative stage would involve focus groups with mobile users. Because the research phenomenon is contemporary and little prior research has been conducted, focus groups would be appropriate for generating ideas and obtaining insights from existing mobile service users and potential users (Carson, Gilmore, Gronhaug, & Perry, 2001). Focus groups are useful when investigating complex behaviour and motivations. By comparing the different points of view that participants exchange during the interactions in focus groups, researchers can examine motivation with a degree of complexity that is usually not available with other methods (Morgan & Krueger, 1993). The use of a focus group is more valuable many times over compared with any representative sample for situations requiring the investigation of complex decision-making processes, as is the case for this research. Based on demographic characteristics, we propose setting up homogeneous groups because discussions within homogeneous groups produce more in-depth information than discussions within heterogenous groups (Bellenger, Bernhardt, & Goldtucker, 1989). These groups would be selected based on main moderating variables identified in the literature, such as, gender/age, quality of life, stage of usage, and voluntariness.

We believe that at least two investigators should conduct all interviews and moderate the focus groups (Denzin, 1989; Patton, 1990). This kind of triangulation reduces the potential bias which is commonly cited as a limitation of interviews and focus gruops (Frankfort-Nachmias & Nachmias, 1996; Yin, 1994).

Quantitative Stage

The last stage of this project would involve an online survey. The collected data would help understand and confirm the determinants and the adoption intentions of the consumers of mobile services. Random sampling should be used to select the sample. We propose that two types of data analysis should be performed on the survey data: descriptive analysis and inferential analysis. Descriptive analysis should be carried out for transformation of raw data into a form that would provide information to describe a set of factors in a situation (Sekaran, 2000). For the inferential analysis, a structural equation model (SEM) should be used to test the refined model.

MANAGERIAL IMPLICATIONS

Mobile technologies and the associated services integrate both the business and social domains of the user's life (Elliot & Phillips, 2004; Knutsen et al., 2005). 3G services in general and location-based services in particular can provide anytime-anyplace tracking of adopters (UMTS, 2003). This creates the opportunity for developing accurate adopter profiles both in their work- and leisure-related domains. In addition, live video and location-based information can also be gathered (Robins, 2003). While such information can help address the needs of adopters better, it can also be misused by businesses for unethical direct business-to-consumer marketing (Casal et al., 2004), raising privacy concerns, overcontrol and overwork of individual adopters (Yen & Chou, 2000). For example, by reducing space and time constraints, mobile communications provide an immensely flexible work environment for some individuals while bringing about overwork or intrusion problems for others (Gerstheimer & Lupp, 2004). As a result, existing privacy protection policies and regulations about employees and consumers should reflect these new conditions. These policies should also account for overcontrol prevention that is likely to result from organisations' attempts to monitor individual performance (Yen & Chou, 2000).

Designing content suitable for mobile phones constitutes an important issue that affects the adoption and diffusion of mobile technology and associated services. This has implications

for service providers, developers, policymakers, and academics. Content providers must design content "for value-contexts specific for mobile use which provide users freedom from complicated configuration procedures, and ubiquitously serve and support current day-to-day individual social practices" (Knutsen et al., 2005a, p. 7). Developers of mobile applications need to recognise that mobile applications are quite different from PC applications (Funk, 2005). Developers should use established standards, such as HTML and Java. More importantly, the usage contexts, the adopters, and their evolving behaviour should be important considerations. Further, because "made-for-the-medium" content type and design may be required (Massey et al., 2005), the available technologies which determine screen size, display quality and processing speeds should be taken into consideration as well (Funk, 2005). The combined effect of these factors on navigation patterns, adopters' cognitive overload, and subjective perceptions about the usability and ease of use of mobile applications can have a critical impact on uptake (Chae & Kim, 2004).

Segmentation of mobile service adopters must not only be based on adopter type (e.g., pioneers, early adopters, majority adopters, and laggards) but also on individual differences. The basis of segmentation should constitute the foundation in developing marketing strategies. For example, individuals with high personal innovativeness or novelty seekers are likely to be willing to experiment with new mobile devices and services, in which case these should be marketed as technological innovations. For individuals who are reluctant to use the same devices and services and are likely to feel discomfort and insecurity while using them, lifestyle promotions may be more appropriate (Dabholkar & Bagozzi, 2002; Teo & Pok, 2003). In addition, endorsements by peers, famous celebrities, or other referent groups may be adequate if these individuals appreciate social norms and image (Hung, Ku, & Chang, 2003; Teo & Pok, 2003). Marketing mobile applications for adopters in one category is likely to frustrate adopters in the other. Therefore, developers and marketers should be prudent in recognising that the confluence of various individual characteristics with varying levels of prior experience, perceptions, and learning predispositions are all likely to influence adoption and retention patterns (Card, Moran, & Newell, 1983; Hung et al., 2003; Massey et al., 2005).

Further, the interface design of mobile applications should encompass both intrinsic and extrinsic motivation dimensions (Moon & Kim, 2001). Based on the proposed model, marketers should promote attributes such as usefulness, ease of use, and enjoyment as important aspects when attempting to persuade potential users in adopting specific mobile phones and services as well as to increase their loyalty and retention (Dabholkar & Bagozzi, 2002; Hung et al., 2003; Lin & Wang, 2005). In particular, personalisation is a well-suited and an achievable goal as mobile phones are identifiable. 3G phones also enable identification of the location of individual handsets, making location-specific marketing possible. Messages promoting the services of businesses, such as restaurants, hotels, grocery stores, and so forth, can be transmitted when users are detected within range (Robins, 2003). Evidence shows that despite privacy concerns, many users of mobile devices are happy to receive unsolicited promotional messages provided that such messages are relevant and personalised (Robins, 2003).

Governments and mobile operators should design appropriate and dedicated strategies to promote the relative advantages of mobile phones and services. Such promotion strategies are important because of their impact on the perceptions of potential adopters (Knutsen et al., 2005). Moreover, the development of wireless communication infrastructures and the provision of incentives are likely to contribute towards the minimisation of the digital divide which results from demographic factors such as varying income levels, education and experience, gender, and age (Lin & Wang, 2005). The digital divide not only prevents the exploitation of the full market potential, but it also

adversely impacts the maximization of benefits for current adopters due to limited network externalities effects (Katz & Shapiro, 1986).

CONCLUSIONS AND FUTURE RESEARCH

User acceptance of mobile technology and related services is of paramount importance. Consequently, a deeper insight into theory-based research is required to better understand the underlying motivations and barriers that will lead users to inhibit them from adopting these technologies and services. This in turn will also help designing technology and service improvements as well as appropriate adoption and diffusion strategies. There are several theoretical models in the literature which attempt to determine acceptance and adoption of new technologies. However, most of these models originate from organisational contexts. As mobile technologies and services add other functional dimensions such as hedonic or experiential aspects, applying extant theories outright to determine the acceptance and adoption of mobile services may be questionable and inadequate.

In this chapter, we have explored and critically reviewed existing technology acceptance theories. Relevant constructs of extant models were discussed in the light of evolving mobile technologies and services and then incorporated into a synthesised acceptance model of mobile services. The proposed model attempts to view acceptance of mobile services beyond traditional organisational borders and permeate everyday social life practices. The proposed model which can be tested empirically provides the foundation to guide further validation and future research in the area of mobile services adoption.

In addition, a plethora of mobile services have become available recently (Alahuhta et al., 2005). Because all services would be available to adopters through a single user interface of the current technology, the appropriation of these services by users may be interconnected and at different stages of maturity (Knutsen et al., 2005). These interconnections are temporal and are also likely to have mutually enhancing, suppressing, or compensating effects on each other (Black & Boal, 1994). This adds dynamism and complexity to acceptance and, therefore, cannot be explained by simply considering factors impacting individual or aggregate adoption at single points in time (Knutsen et al., 2005; Pagani, 2004). Consequently, future research should develop and test dynamism-compatible acceptance models because these models may provide a deeper understanding and help in explaining how and why technology acceptance perceptions change as the appropriation process progresses. Further, with a wide variety of mobile devices and services available and their applicability in distinct spheres of life, the definition of a unit of analysis in mobile services adoption has become a challenging task (Knutsen et al., 2005). Additional research in this aspect is also needed.

Chapter 1.17
Multimedia Databases

Mariana Hentea
Southwestern Oklahoma State University, USA

INTRODUCTION

The Internet and technologies such as high-capacity storage devices, broadband telecommunications systems, and multimedia development software systems have accelerated the development of new applications based on the use of multimedia database systems. A multimedia database is a repository of different data objects (text, numeric values, Boolean values, dates, graphical images, video clips, and sound files). Examples of applications based on multimedia databases include news and stock market information on demand; movies on demand; home shopping; medical systems; trademark, patent, and copyright databases; geographic information systems (GIS); weather forecasting; Computer Aided Design (CAD) systems; architectural design; fabric and fashion design; interior design; photographic libraries; art gallery and museum management; law enforcement; criminal investigations; military reconnaissance and surveillance; scientific experiments; and educational systems.

The real-time nature and different kinds, including the size of multimedia data, cause problems for the design, implementation, and management of multimedia databases. Multimedia data requires use of specific technologies to reduce the size of the media data so it could be stored within the database. For example, NASA's Earth Observation System generates a terabyte (1,000 gigabytes) of data a day. This data comprises images recorded from orbiting satellites by video and infrared cameras that are downloaded to earth. The software chosen by the National Library of Australia is the TeraText™Database System, providing a single access point to over 600,000 images from 18 Australian cultural institutions, including libraries, museums, archives, and galleries representing images related to Australia's cultural heritage from the late 18th century through to the present day. The TeraText™Database System is known for its scalability, flexibility, speed, and sophistication. The increasing importance of multimedia applications and the introduction of SQL3 in 1999 have favored changes to traditional relational databases. These resulted in the implementation of features to store and manipulate large objects within object-relational databases. One example is Oracle9i, which is an object-re-

lational database management system that offers capabilities for holding media data. Through the use of media data types, Oracle interMedia software enables the Oracle9i database management system to manage and deliver image, audio, video, and geographical location data in an integrated fashion with other enterprise information.

The creation, storage, and data modeling techniques for multimedia data objects and retrieval of objects are main issues in the development of multimedia databases. Other issues include authenticity, integrity, media metadata, automatic video capture and editing, mobile media applications, scheduling, and quality of multimedia delivery over a network (Bourbakis, 2004; Shu & Yu, 2004). The following section provides a brief overview of the multimedia retrieval methods.

MULTIMEDIA QUERIES

The representation, structure, and retrieval of objects evolved in time from simple conventional data to more complex multimedia data objects such as video and audio. At the beginning, the retrieval of objects was treated as a single data item using queries based on indexing approaches and identification of the attributes that describe an object. However, this method proved to be inefficient. Retrieval of images from a multimedia database is based on similarities. Modern computer technology can be used to extract images of objects from pictures and videos, but the ability to identify these objects semantically is beyond the capabilities of current research. Because computers cannot add semantic interpretation to images, this must be added manually. Visual queries based on recognizing objects on the basis of their color, shape, or texture and other graphical characteristics are possible. Objects can be indexed using feature values and retrieved based on the similarity to the feature values of other objects. Feature values can be derived for an entire media object or just a specific part of its content. Features that can be measured include shape, color, texture, initial position, and direction and speed of motion. Features can be difficult to quantify and their identification may require complicated and lengthy techniques for extraction. The measurement value for a feature may be a representation of the shape or a histogram representing the color distribution of the object. Several of the methods for the extraction of feature values require use of advanced algorithms based on artificial intelligence (AI) techniques such as data mining (Shih & Wang, 2004; Thuraisingham, 2001), artificial neural networks and fuzzy logic (Tsai, McGarry, & Tait, 2003), and computer vision (Dunckley, 2003). These techniques are explored to enhance the feature extraction and increase the quality of multimedia retrieval and processing.

If the retrieval of images is to be based on keywords, then either the images must be manually indexed, or the objects within the images must be automatically recognized and appropriate keywords added to the index. Whether automatic or manual indexing is used, the descriptive words added by the indexer may or may not conform to the keywords employed by the user. One approach utilizes two different keyword indexing systems, conceptual keyword and scene description keyword, to retrieve images from a database. However, the developed techniques for indexing and retrieval are abundant, but there are no universally accepted techniques for feature extraction, indexing, and retrieval (Deb & Zhang, 2004).

Currently, new methods are emerging and being implemented for retrieving multimedia data objects (e.g., audio and video) based on their content. Research of content-based retrieval of multimedia information started in the early ’80s with investigations into the retrieval of static images, which in turn was based on pattern recognition research of the ’70s. Research into the retrieval of images from video has received more attention during the ’90s. The approaches to aiding the retrieval of visual images from graphics or videos can be classified into the following categories:

- Keyword, in which the content of the images is described by an indexer using keywords or a textual abstract.
- Content-based image retrieval of features that can be automatically extracted from images. The features are selected according to certain criteria, such as color, texture, or shape; by allowing the user to sketch images and then retrieve similar images from the database; by discerning the motion path of an object; and by identifying one object from its position relative to another. There are a number of commercially available systems, such as IBM's QBIC and Virage products, which are based on the retrieval of images using their non-semantic features.
- Concept-based retrieval in which semantic interpretation of the objects is added, such as identifying an object as a named person, a type of vehicle, etc. There are a number of systems in this category such as Infoscope and WebSEEk. WebSEEk is a semiautomatic system for retrieving, analyzing, categorizing, and indexing visual images from the World Wide Web.

Many algorithms have been focused on content-based image indexing, but researchers have been investigating an indexing system based on the spatiotemporal characteristics of objects that appear in multimedia applications. Spatial positions are represented by two-dimensional coordinates while temporal relationships are represented by a single dimension, time.

Other systems have been developed for automatically indexing video streams received in real time. The source of the video may be, for example, television broadcasts or security cameras. The incoming video data stream is passed to an event detection module that detects scene changes, significant audio changes, camera operations, and the motion of objects in the video. The event detection module uses this information to define the boundaries of what the authors refer to as events. The event boundaries are specific to the application; in broadcast television these may be scene changes or the appearance of captions, and in security surveillance video the beginning of a new event may be signified by a new object entering the scene. The first frame of an event is used as its key frame. The key frame, the event itself (comprising both video and audio), and its time index will be stored for a certain period of time. The key frames provide a visual index for the viewer. The view of the index displayed can be changed to show a more global view, with an index that includes every key frame. Content-based queries are often combined with text and keyword predicates to get powerful retrieval methods for image and multimedia databases.

Hypermedia video links is another system for content-based retrieval of information from a video database. Raw video data is stored in the video storage. Video clips can be extracted from the video object database using video object software. Developers of hypermedia applications can also use the video object manager to retrieve and play video data objects. The video data structure for the hypermedia multimedia authoring environment is quite straightforward. Using the video object manager, the developer of an application can extract clips manually from a video to create primitive video data objects. Attributes, such as display size and frame rate, inherited from the video from which it is extracted can be associated with the clip or altered by the developer. Complex data objects can be created using combinations of primitive and existing complex video data objects. The clips within a complex video data object are arranged in the sequence in which they will be played back. The next section introduces known multimedia management products, examples of applications using these products, and significant standards.

KNOWN MULTIMEDIA MANAGEMENT PRODUCTS

Corporations such as IBM, Virage, Silicon Graphics, ARDA, Oracle, Autonomy, and ALPHATECH are major providers of multimedia database management, communication, and content management software for corporations, media and entertainment companies, universities, and government agencies worldwide.

The IBM's CueVideo project provides technologies to automatically summarize and index videos and to make them much easier to browse. One approach is using audio stream for search and using video stream for quick browsing in a complementary manner to provide the desired video search functionality (Brown et al., 2001). CueVideo is an ongoing research project to address the challenges of large video databases.

One example of a mobile multimedia application is MobiDENK (Krosche, Baldzer, & Boll, 2004) for monument conservation. The Hermitage museum's Web site uses an IBM product, QBIC (Query By Image Content), for searching archives of world-famous art. QBIC is a system developed by IBM to explore various content-based retrieval methods. Queries in QBIC can be based on color and texture patterns, user-drawn sketches, example images, camera and object motion, or other graphical information, such as the color balance; e.g., retrieve all images with 30% blue and 10% yellow colored pixels. The QBIC database can handle both still images and video clips. In common with other systems, videos are divided into shots, using techniques similar to those described above. One frame from each clip is extracted or generated as a representative frame for the clip. In a motion sequence there may not be a single frame that is representative of the entire shot. In this case, QBIC constructs an image of the complete background from the sequence of frames and on to this superimpose images of the foreground objects.

QBIC's capabilities are available in DB2 Image Extenders, which are components of IBM's scalable, multimedia, Web-enabled DB2 Universal Database. IBM developed different multimedia retrieval applications for the DB2 Universal Database as follows:

- DB2 Audio Extender enables audio retrieval.
- DB2 Image Extender enables image retrieval. Visual features such as color and texture patterns are used for search criteria. For example, a photographic database may be queried for thumbnail images of all pictures stored in GIF format, and the name of each picture's photographer can be listed. Then, Image Extender invokes a browser.
- DB2 Video Extender enables video retrieval. Video and traditional business data may be included in a single query.

For example, Image Extender is used to store print ads, Audio Extender for broadcast ads, and Text Extender for ad scripts. The user can retrieve all the objects in a single query and then preview video ads as video storyboards using the Video Extender.

Hillsborough County uses Virage's products to create a central digital archive of government proceedings, which automates a formerly manual workflow and provides real-time access to content. Virage products include capabilities as follows:

- IDOL provides the infrastructure for capturing, feeding, and delivering rich media through the enterprise.
- VS Archive is a software solution used by enterprises to store, categorize, manage, retrieve, and distribute video, audio, and other rich media content. It includes new features such as advanced conceptual retrieval and automated hypertext linking to enterprise information found in more than 300 different data types.

- VS News Monitoring is a real-time monitoring and content management solution used by enterprises and government agencies to automatically track content for time-sensitive, strategically significant events. New features within VS News Monitoring include real-time data access and advanced concept-based retrieval. Concept-based retrieval is especially important for monitoring and searching news feeds in foreign languages, because users may work in second languages or rely on transcriptions that may contain misspelled words. With IDOL, VS News Monitoring not only proactively alerts users to broadcast news but also delivers related internal content as well as information from Web sites.
- VS Webcasting is an enterprise software solution that simplifies and streamlines the entire workflow for producing live Webcast events and on-demand or rebroadcast presentations for large audiences.

Silicon Graphics and Virage combine products to create breakthrough media management systems. For example, Virage Media Management System and the Silicon Graphics StudioCentral asset management system enable companies to automatically and intelligently catalog large libraries of videotape and multimedia content into a compact, online database. The combined products provide users with a complete media management system to find and manage their media through a simple Web browser. The next section discusses main standards for multimedia applications.

MAJOR STANDARDS

Many aspects of the multimedia information life cycle are affected by regulatory compliance (Golshani, 2004), and requirements for latest object database management development standards are proposed (Cardenas, Pon, Panayiotis, & Hsiao, 2003). MPEG-7 and MPEG-21 standards have been essential for the development of multimedia applications. The MPEG-7 standard, formally named Multimedia Content Description Interface, provides a rich set of standardized tools to describe multimedia content. Both human users and automatic systems that process audiovisual information are within the scope of MPEG-7. MPEG-7 offers a comprehensive set of audiovisual description tools (the metadata elements and their structure and relationships, which are defined by the standard in the form of descriptors and description schemes) to create descriptions (i.e., a set of instantiated description schemes and their corresponding descriptors at the user's will), which form the basis for applications enabling efficient access (search, filtering, and browsing) to multimedia content (Chang, Kikora, & Puri, 2001).

MPEG-21 has established a work plan for future standardization. Nine parts of standardization within the multimedia framework have already started.

FUTURE TRENDS

Content-based retrieval is a very active area of research despite the advances that have been made. Recently, Virage announced its participation in the Video Analysis and Content Extraction (VACE) media communication and content program sponsored by ARDA. The research project will be focused on the development of video content extraction technology. The initial focus of the VACE program is to develop automatic detection and recognition technologies from various video-related sources, including indoor and outdoor activities, unmanned air vehicles, and television news broadcasts. Over time, VACE technologies aim to provide significant improvement in indexing and retrieval, understanding, image processing, data mining, filtering and selection,

and storage and forwarding mechanisms. In addition, research is occurring on new compression techniques, such as wavelet, vector, and fractal methods, to ensure multimedia delivery with high quality.

In the future it should be possible to automatically recognize and identify objects that appear in still images and video. To achieve this, it will almost certainly require significant developments in the application of artificial intelligence techniques to multimedia database systems. These developments will lead to automatic recognition and indexing of video footage and still images and result in the development of a wide range of applications relying on the content-based retrieval of multimedia data objects.

CONCLUSION

Multimedia is becoming present everywhere: at home, business, school, hospital, road, etc. Digital media has been acknowledged as a standard data type, allowing for increased personal communications, business-to-employee, business-to-business, and business-to-consumer applications. These applications require complex and large multimedia databases, causing changes in computing and solution architectures to be maintained by organizations. In addition, technologies pertaining to communication, coding, compression, content distribution, storage, mobile computing, media servers, cryptology and watermarking, and digital media management will grow in order to address solutions for multimedia services. While creating digital media is not expensive, it is generally expensive to manage and distribute it. Browsing large multimedia databases can become complex and will demand faster and more efficient algorithms for indexing and retrieval of structures. In addition, multimedia distribution in a mobile computing environment will continue to be the center of research for next-generation multimedia systems.

KEY TERMS

Content-Based Retrieval: Method for automatic multimedia content features extraction.

Feature: An attribute derived from transforming the original multimedia object by using an analysis algorithm; a feature is represented by a set of numbers (also called feature vector).

Feature Extraction: Use of one or more transformations of the input features to produce more useful features.

Feature Selection: Process of identifying the most effective subset of the original features.

Indexing: Mechanism for sorting the multimedia data according to the features of interest to users to speed up retrieval of objects.

Metadata: Information about multimedia data objects, applications, processing, and delivery requirements.

Multimedia Database: A repository of different data objects such as text, graphical images, video clips, and audio.

O. Kao
University of Paderborn, Germany

INTRODUCTION

Sensing and processing of multimedia information is one of the basic traits of human beings. The development of digital technologies and applications allows the production of huge amounts of multimedia data. The rapidly decreasing prices for hardware such as digital cameras/camcorders, sound cards and the corresponding displays led to wide distribution of multimedia-capable input and output devices in all fields of the everyday life, from home entertainment to companies and educational organisations. Thus, multimedia information in terms of digital pictures, videos, and music can be created intuitively and is affordable for a broad spectrum of users.

An important question in this context is related to the archiving of the acquired information. The old-fashioned albums with pictures from holidays, children, special occasions, and so forth are replaced by photo-CDs and DVDs. Analogously, digital videos are edited, valorised by including meta-information (occasion, place, date …) and archived on DVDs. If a particular scene, image, or sound file is needed, then one can use its memory to find the corresponding medium. This type of organisation is surely not applicable to large multimedia archives, which often exist in industrial and educational sectors and where Petabytes worth of multimedia data are produced year for year. All this information has to be systematically collected, registered, stored, organised, and classified. Therefore, in many branches professional archives for such multimedia information are established, such as document management systems, digital libraries, photo and video archives used by public authorities, corporations, broadcasting and TV companies, as well as archives for satellite and surveillance photos. The scope and spread of such systems grow day by day and lead to new demands for efficient retrieval of the archived information

based on user-specific description of the sought image, video or audio.

The search for a medium similar to the given one is, due to the complexity of multimedia information, a very challenging problem and requires a number of novel mechanisms. Beside the search procedures, also methods to formulate queries, and ways to visualise the results have to be provided. Moreover, the search has to be performed efficiently in order to achieve acceptable response times for the user. Therefore, a combination of modern multimedia archives with powerful parallel and distributed architectures described in this article is mandatory for the integration of multimedia retrieval into real-world applications.

BACKGROUND

The necessity for organisation and retrieval of multimedia data led to development of a large number of prototypes and operational multimedia database management systems, which manage the multimedia data in terms of storage, annotation, and retrieval. In the early years this task was tended to by existing database management systems (DBMS) with multimedia extensions. The basis for representing and modelling multimedia data in such systems is so-called Binary Large Objects (BLOBs), which store images, video and audio sequences without any formatting and analysis done by the system. The media are saved in the current form in the database and their additional information – called meta-information – is inserted into the database tables. Typically, the file name, categories and additional key words entered by the user serve as meta-information. Once the user submits a key word about the sought media, the blocks with meta-information are searched using the existing database functions and compared with the input. In case of a key word match, the corresponding media is presented.

These extensions reflect a certain aspect of multimedia database systems, but this approach does not satisfy the requirements of multimedia archives, as the manual annotation of the media is too time-consuming and not applicable in real-world applications. Furthermore, key words are not sufficient to represent content of images or videos entirely (*An image says more than 1000 words*). Therefore, the media annotation and retrieval has to be content-based; that is, features describing the multimedia content have to be extracted automatically from the media itself and compared to the corresponding features of the sample medium. The functionality of such a multimedia database is well defined by Khoshafian and Baker, (1996):

"A multimedia database system consists of a high performance DBMS and a database with a large storage capacity, which supports and manages, in addition to alphanumerical data types, multimedia objects with respect to storage, querying, and searching."

The DBMS is already provided by traditional databases and therefore will not be discussed in the following sections. Instead, the focus is set on the mechanisms for multimedia retrieval and high-performance implementation.

MULTIMEDIA RETRIEVAL

The content-based annotation of multimedia data requires the integration of additional information, which can be classified into the following categories:

- Technical information describes details of the recording, conversion, and storage. Examples: filename, resolution, compression, frame rate.
- Extracted attributes are features that are deduced by analysing the content of the media directly. Examples: average colour or colour histograms of an image, camera motion in videos, pitch in audio files.

Table 1. Prominent examples for image, video and audio databases.

• Image databases
  o Qbic (Flickner, Sawhney et al., 1995)
  o Photobook (Pentland, Picard & S claroff, 1994)
  o Surfimage (Nastar, Mitschke et al., 1998)
• Audio databases
  o VARIATIONS (Dunn & Mayer, 1999)
  o MUSART (Birmingham, Dannenberg et al., 2001)
• Video database s
  o VideoQ (Chang, Chen et al., 1998)
  o Virage Video Engine (Hampapur, Gupta et al., 1997)
  o CueVideo (Ponceleon, Srinivasan et al., 1998)

- Knowledge-based information links the objects, people, scenarios, and so forth detected in the media to entities in the real world.
- World-oriented information encompasses information on the producer of the media, the date and location, language, and so forth.

Technical and world-oriented information can be modelled with traditional data structures. The knowledge-based information assumes semantic analyses of the media, which is nowadays still not possible in general. However, many recent research efforts in this direction promise the applicability of semantic information in the future (Zhao & Grosky, 2002).

Most of the existing multimedia retrieval systems are specialised to work on media of a limited domain, for example news (Christel & Hauptman, 2002; Yang & Chairsorn, 2003), American football (Li & Sezan, 2002), or integrate general retrieval algorithms like face, speech or character recognition. They use features extracted from the media content to annotate and retrieve the multimedia objects, which are usually related to the colour, edge, texture, layout properties in case of images or consider object motion in case of videos or specific tone sequences for audios. Table 1 gives an overview of several prominent, specialised systems, which introduced main research retrieval concepts to the scientific community. Meanwhile, many of these systems became a part of commercial products or a part of a general multimedia archive. A survey is provided in Venters and Cooper (2000).

In the following, the retrieval workflow for multimedia data will be depicted by considering images as an example. The user has a specific image in mind and starts a query for this specific image or for similar samples. The user can for example browse the data set or give a suitable key word. However, for content-based similarity search, sophisticated interfaces are necessary:

- Query by pictorial example: the user supplies the system with a complete sample image, which is similar to the sought one.
- Query by painting: the user sketches the looked-for image with a few drawing tools (Rajendran & Chang, 2000).
- Selection from standards: lists of sample instances – called standards – can be offered for individual features.
- Image montage: the image is composed of single parts similar to a mosaic.

All approaches have individual advantages as well as shortcomings; thus a suitable selection depends on the domain. However, the query by pictorial example is one of the most often applied methods since it provides the greatest degree of flexibility.

In the next step the query image is compared to all archived images in the database based on the extracted features. Each feature emphasises one or more aspects of the image, usually related to colour, texture and layout. These features are extracted off-line (at creation time) for the archived images and online (at query time) for the given sample image. Thus, after the analytical phase, the images are represented by consistent feature vectors, which can be directly compared using similarity metrics or functions. For this purpose well-known metrics such as the (weighted) Euclidian Distance or specially developed and adapted metrics like Earth Mover Distance can be applied (Rubner & Tomasi, 2000).

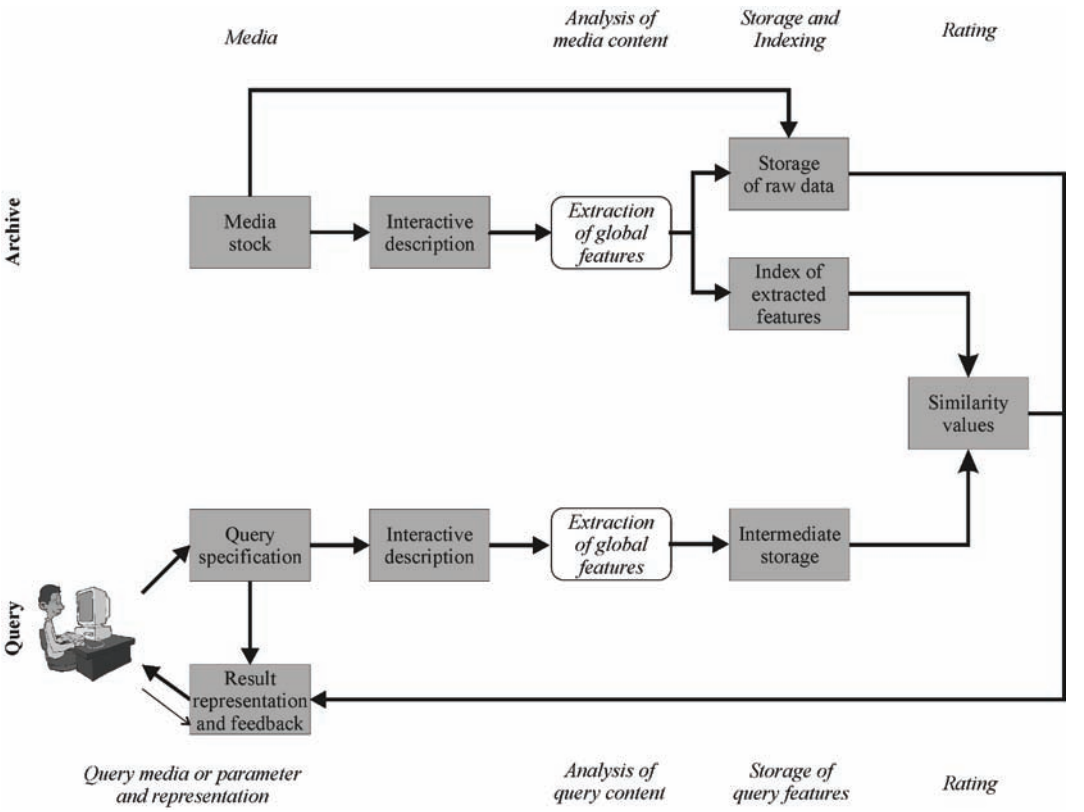
The result of this comparison is a similarity value for the query and the analysed image. The process is repeated for all n images in the database, resulting in a similarity ranking. The first k entries, k being a user-defined constant, represent the k best hits, whose raw data are then displayed. Figure 1 describes the global workflow.

The comparison process can be accelerated by using index structures. These contain a-priori extracted features and are organised in a way that the comparisons can be focused to a certain area around the query. A novel approach and an overview of often-applied index structures are provided in Tuncel and Ferhatosmanoglu (2002). A survey of specialised retrieval techniques is provided for example in Rui (1999).

HIGH-PERFORMANCE COMPUTING FOR MULTIMEDIA RETRIEVAL

The database architecture – software and hardware – is decisive for the efficiency and thus for

Figure 1. General retrieval workflow



the usability of a multimedia archive. Because of their high storage and computing requirements, multimedia databases belong to those applications which rapidly hit the limits of the existing technology.

The widespread client/server architectures are – in their usual form – not fit for multimedia database implementations. Firstly, a centralised organisation of a media server requires immense storage and computation resources. With a growing number of user queries and data to be organised, such a centralised system will quickly reach the borders of its capabilities and the quality of service is no longer fully sustainable.

One possible solution for this problem is offered by distributed and parallel architectures, where multiple processing elements (PEs) work cooperatively on an efficient solution of a large problem. The data and the programs are spread over several nodes, so that the processing is accelerated (parallel processing) or the path to the user is shortened (distributed processing, e.g., video-on-demand servers).

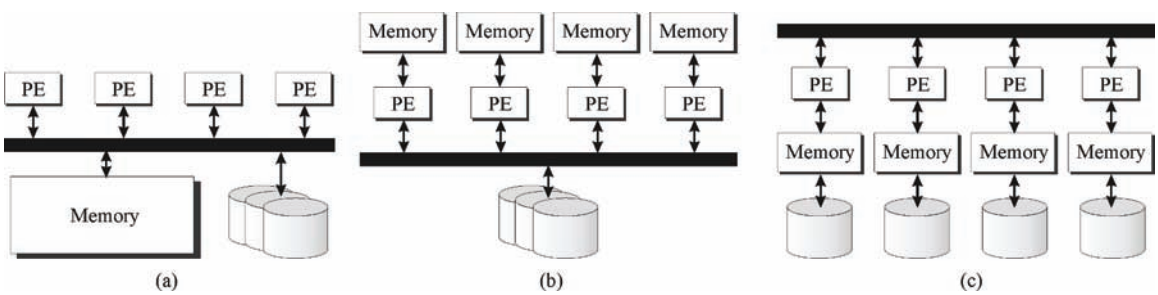
There are many possible ways for the organisation of such architecture; the well-known are shared everything, shared disk, and shared everything architectures shown in Figure 2.

Due to the shared utilisation of the hard disks, buses, and memory in case of shared disk and shared everything architecture respectively, the data throughput in these architectures is rather low and the response time long. Experimental measurements executed in Bretschneider, Geisler and Kao (2002) showed that shared nothing architectures – in particular cluster-based systems – with an appropriate data distribution across the multiple nodes are most suitable for the realisation of an efficient multimedia retrieval. A node is defined as an entity consisting of a PE, a memory, a storage resource, and a network adapter.

The database running on this architecture can be denoted as a parallel and distributed database: The data are distributed over all nodes, but logically combined in a single entity, making it look like a single database system from the outside. The only difference noticeable to the user is the performance improvement of the system, which results from utilising the parallelism in the computer network. Further characteristics concern the optimisation of queries, controlling parallelism, recovery, integrity, and security. All these aspects are already well defined for conventional database systems, and have been analysed in detail. However, the possibility of a geographically separated data distribution introduces new constraints and requires additional communication and synchronisation mechanisms. The problems grow more complex when heterogeneous computer architectures, long processing times per data set – as in multimedia applications –, hardware and software failures, and so forth have to be considered.

As already noted, the data distribution is a crucial efficiency aspect and has to fulfil numerous, sometimes even conflicting requirements: The

Figure 2. Classification of parallel architectures: a) shared everything; b) shared disk; c) shared nothing



data needed by an operation should – if possible – all be on one node (*data locality*). On the other hand, as many operations as possible should be processed in parallel, that is, the data should be distributed evenly among all available nodes. A drawback of the broad distribution is given by the time-consuming data transfer between the individual nodes, which affects the performance significantly. Thus a general distribution is not applicable; hence it has to be tailored for the current application. One possible solution will be presented in the following by considering the cluster-based multimedia database Cairo as an example (Kao & Stapel, 2001).

The general Cairo architecture shown in Figure 3 consists of:

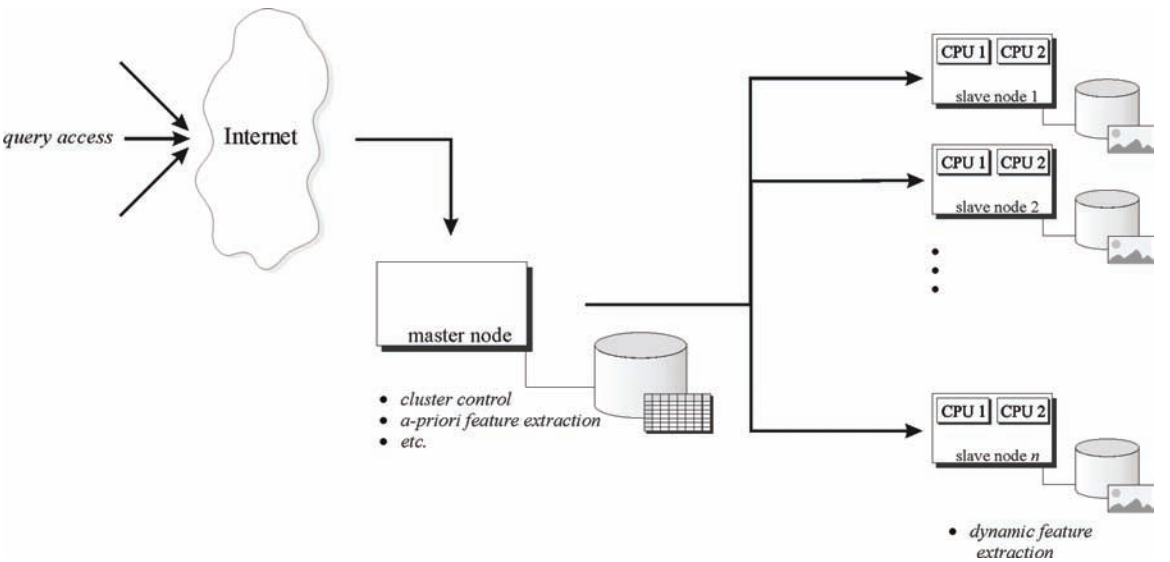
- Query stations host the Web-based user interfaces for the access to the database and for the visualisation of the retrieval results.
- Master node controls the cluster, receives the query requests and broadcasts the algorithms, search parameters, the sample media, features, and so forth to the compute nodes. Furthermore, it unifies the intermediate results of the compute nodes and produces the final list with the best hits.
- Compute nodes perform the image processing and comparisons. Each of these nodes contains at least one partition and executes all operations with the data stored on the local devices. The computed intermediate results are sent to the master node.

The distribution of the media stock across the individual cluster nodes is created according to the following requirements:

- Similar storage sizes of the partitions and thus an even distribution of the media across the individual nodes,
- Computation reduction for the retrieval, and
- Minimising the communication between the cluster nodes.

Cairo uses a content-independent, size-based strategy for the available media stock that creates a set of partitions $P = P_1 \cup P_2 \cup \ldots \cup P_n$ where $P_i \cap P_j = \varnothing$ and $size(P_i) \approx size(P_j)$ for all i,j, $i \neq j$. The

Figure 3. Schematic of the Cairo cluster architecture



current image under investigation is assigned to the node with the least storage space used. This process is repeated until all images are distributed to the partitions.

The processing of a partition P_i is executed per media instance. The individual operations are independent of one another, so the order of execution is irrelevant. This initial partitioning makes it possible for all nodes to have uniform processing times, assuming a homogenous, dedicated execution platform. The management overhead depends on the operator applied and the structure of the partial results. However, this time is usually neglectable, compared to the media processing times.

The advantage of a static distribution is that expensive computations and data transfers are not necessary during runtime and the partitioning can be manually optimised and adapted to a given application. On the other hand, short-term reactions to variable workloads among the nodes are not possible. A dynamic distribution of the data is done during runtime and considers the current workload of the nodes, as well as the number and the structure of pending queries. Idle times can be minimised by continuously re-distributing the data, and increasing the total throughput. Unfortunately, the long communication time for multimedia data often eliminates all performance advantages gained through the parallel processing.

After the partitions are created, these are distributed evenly over the cluster nodes, allowing parallel retrieval by executing the same operations on all nodes with the local media subset. The implementation is based on the following components:

- Transaction manager encompasses the analysis of the transformations to be executed and the order of the operations.
- Distribution manager receives a list of algorithms to be executed and a set of media instances as input. Then the programs for the analysis and comparison are compiled and sent to the computing managers.
- Computing manager controls the execution of the extraction algorithms with the local data. The process runs on each cluster node and supervises the communication with the master node.
- Result manager: The data partitioning in disjoint subsets results in a sub-ranking per node that need to be unified by the result manager.
- Update manager realises the media insertion in the database. The raw data are transformed in a uniform format and tagged with a unique identifier. All procedures for feature extraction are then applied. Finally, the cluster node, on whose hard disk the raw data are to be stored, is determined.

The described organisation was successfully implemented and evaluated in real-world scenarios. The minimised communication between the nodes allows a nearly full utilisation of the available compute resources and leads to a linear speedup; that is, the response time is shortened by a factor equal to the number of included nodes.

Other performance relevant parts of a multimedia database system are still the subject of research. Examples are given by the disk scheduler for multimedia storage (Huang & Huang, 2004) and scheduling for broadcasting videos and audios (Yoshihisa & Tsukamoto, 2003).

FUTURE TRENDS

Despite the immense development of multimedia in recent years, the efficient organisation and retrieval of multimedia data still remains a large scientific challenge. The growing number of multimedia data and new applications fields are the driving forces.

The consideration of semantic information is necessary to realise a human-like retrieval

approach for images, video and audio and to integrate multimedia components in the semantic Web for ubiquitous access. Furthermore, the current restriction of the most databases to a single media type will be eliminated by methods for multimodal retrieval. For example, the editor of a newscast needs access to videos from news agencies, images from photographs, audios files from radio and text from newspaper articles. Merging the information into a single database requires methods to classify all these media instances and measure the content-based similarity between them. Speech recognition for example can be used to compare audio or video files with textual information. Multimodal access accommodates different user profiles or device capabilities and can help to receive improved query results.

Not only different media types but also media data from different providers have to be merged to create a large distributed multimedia warehouse or a multimedia grid. MPEG-21 is designed for the content description and digital rights management. Load balancing, data distribution and quality of service considerations are necessary to achieve high performance and consumer satisfaction in a very heterogeneous environment. Finally, the multimedia information has to be accessible for mobile devices using standards such as UMTS.

CONCLUSION

Traditional databases offer a search for certain media instance based on describing key words. The main invention of multimedia databases is the possibility to search directly on the media content. However, this time-consuming process has to be performed in parallel to achieve acceptable response times. The cluster architecture scales well even for a high number of processing elements, but if and only if the underlying data partitioning strategy is suitable for the given application.

Further research is needed to give the user feedback on how to improve the query and how to supply the system with feedback about the relevance of delivered results. A further aspect is the improvement of the database design, especially data distribution in parallel environments. Furthermore, advanced methods for semantic content description have to be exploited.

KEY TERMS

A-Priori Feature Extraction: Analysis and description of the media content at the time of insertion in the database. The gained information is stored in a database and enables content-based retrieval of the corresponding media object without actually accessing the latter.

Cluster: Parallel architecture that contains multiple "standard" computers connected via a high performance network that work together to solve the problem.

Dynamic Feature Extraction: Analysis and description of the media content at the time of querying the database. The information is computed on demand and discarded after the query was processed.

Feature Vector: Data that describe the content of the corresponding multimedia object. The elements of the feature vector represent the extracted descriptive information with respect to the utilised analysis.

Load Balancing: Techniques to distribute the tasks over the single processors in parallel systems in a way that idle time is minimized.

Multimedia Database (after Khoshafian & Baker): A multimedia database system consists of a high performance database management system and a database with a large storage capacity, which supports and manages, in addition to alphanumerical data types, multimedia objects with respect to storage, querying, and searching (Khoshafian & Baker, 1996).

Quality of Service (QoS): The collective term for all demands on the recording and the replaying procedures, which refer to generating and maintaining a continuous data stream.

Query by Example/Sketch/Humming: Methods to formulate queries in multimedia databases. The user provides an example media file and the result of the database system is a set of similar media files. If no example is available the user can draw a sketch or hum a melody.

Retrieval: Accessing stored information from the database.

Chapter 1.19
Multimedia Information Filtering

Minaz J. Parmar
Brunel University, UK

Marios C. Angelides
Brunel University, UK

INTRODUCTION

In the film *Minority Report* (20th Century Fox, 2002), which is set in the near future, there is a scene where a man walks into a department store and is confronted by a holographic shop assistant. The holographic shop assistant recognises the potential customer by iris-recognition technology. The holographic assistant then welcomes the man by his name and starts to inform him of offers and items that he would be interested in based on his past purchases and what other shoppers who have similar tastes have purchased. This example of future personalised shopping assistants that can help a customer find shopping goods is not too far away from becoming reality in some form or another.

Malone, Grant, Turbak, Brobst, and Cohen (1987) introduced three paradigms for information selection, *cognitive*, *economic*, and *social*, based on their work with a system they called the Information Lens. Their definition of cognitive filtering, the approach actually implemented by the Information Lens, is equivalent to the "content filter" defined earlier by Denning, and this approach is now commonly referred to as "content-based" filtering. Their most important contribution was to introduce an alternative approach that they called social (now also more commonly called collaborative) filtering. In social filtering, the representation of a document is based on annotations to that document made by prior readers of the document.

In the 1990s much work was done on collaborative filtering (CF). There were three systems that were considered to be the quintessential recommender systems. The Grouplens project (Miller, Albert, Lam, Konstan, & Riedl, 2003) initially was used for filtering items from the Usenet news domain. This later became the basis of Movielens. The Bellcore Video recommender system (Hill, Stead, Rosenstein, & Furnas, 1995), which rec-

ommended video films to users based on what they had rented before, and Ringo (Shardanand & Maes, 1995), which later was published on the Web and marketed as Firefly, used social filtering to recommend movies and music.

BACKGROUND

Filtering multimedia content is an extensive process that involves extracting and modeling semantic and structural information about the content as well as metadata (Angelides, 2003). The problem with multimedia content is that the information presented in any document is multimodal by definition. Attributes of different types of media vary considerably in the way the format of the content is stored and perceived. There is no direct way of correlating the semantic content of a video stream with that of an audio stream unless it is done manually. A content model of the spatial and temporal characteristics of the objects can be used to define the actions the objects take part in. This content model can then be filtered against a user profile to allow granular filtering of the content, allowing for effective ranking and relevancy of the documents.

Filtering has mainly been investigated in the domain of text documents. The user's preferences are used as keywords, which are used by the filters as criteria for separating the textual documents into relevant and irrelevant content. The more positive keywords contained in a document, the more relevant the document becomes. Techniques such as latent semantic indexing have found ways of interpreting the meaning of a word in different contexts to allow accurate filtering of documents using different syntax, but allow the same semantics to be recognised and understood.

Text documents adhere to the standards of the language they are written in. Trying to do the same for AV data streams, you are faced with the problem of identifying the terms in the content itself. The terms are represented as a series of objects that appear in the content, for example, a face in an image file. These terms cannot be directly related to the objects as there is no method of comparison, or if there is, it is complex to unlock. The title of the document and some information might be provided in the file description, but the actions and spatial and temporal characteristics of the objects will not be described to a sufficient level for effective analysis of relevancy.

MAIN THRUST OF ARTICLE

Information-filtering techniques have been applied to several areas including American football (Babaguchi, Kawai, & Kitahashi, 2001), digital television (Marusic & Leban, 2002), Web applications (Kohrs & Merialdo, 2000), and ubiquitous and pervasive device applications (Tseng, Lin, & Smith, 2002).

Filtering multimedia information requires different approaches depending on the domain and use of the information. There are two main types of multimedia information filtering: collaborative and content based. If the user wants a subjective analysis of content in order to find a recommendation based on their individual preference, then they use collaborative filtering, also known as social or community-based filtering. If, on the other hand, they require an objective decision to filter information from a data stream based on their information needs, then they use content-based filtering.

All of the above systems use either collaborative or content-based filtering or a combination of both (hybrid) as the techniques for recommending predictions on candidate objects. There are existing information-filtering models outside these classic techniques such as temperament-based filtering (Lin & McLeod, 2002), which looks at predicting items of interest based on temperament theory. It works on the same principle as social filtering. Unlike social filtering, the users are grouped on temperaments of the users and not on similar item selection.

Content-Based Filtering

Content-based filtering is suited to environments where the user requires items that have certain content features that they prefer. Collaborative filtering is unsuitable in this environment because it offers opinions on items that reflect preferences for that user instead of providing filtering criteria that tries to disseminate preferred content from a data stream based on a user's preference. Personalised video summaries are the perfect domain to use content-based filtering. The reason for this is that a user will be interested in certain content only within any video data stream. For example, when watching a football game, the user may only be interested in goals and free kicks. Therefore, users can state what content features and other viewing requirements they prefer and then filter the footage against those requirements.

The content-based approach to information filtering has its roots in the information retrieval (IR) community and employs many of its techniques. The most prominent example of content-based filtering is the filtering of text objects (e.g., mail messages, newsgroup postings, or Web pages) based on the words contained in their textual representations. Each object, here, text documents, is assigned one or more index terms selected to represent the best meaning of the document. These index terms are searched to locate documents related to queries expressed in words taken from the index language. The assumption underlying this form of filtering is that the "meaning" of objects and queries can be captured in specific words or phrases. A content-based filtering system selects items based on the correlation between the content of the items and the user's preferences as opposed to a collaborative filtering system that chooses items based on the correlation between people with similar preferences (van Meteren & Someren, 2000).

The main problem with content-based filtering is that it does not perform well in domains were the content of items is minimal and the content cannot be analysed easily by automatic methods of content-based retrieval (e.g., ideas and opinions). Users with eclectic tastes or who make ad hoc choices are given bad recommendations based on previous choices. For example, Dad, who usually buys classic rock CDs for himself, purchases a So Solid Crew album for his 12-year-old son. He may start getting recommendations for hardcore garage dance anthems every time he logs in. CF does not suffer this problem as it will rank on other users' recommendations of similar choices. Comparative studies have shown that collaborative-filtering recommender systems on the whole outperform content-based filtering.

Collaborative Filtering

A purely content-based approach to information filtering is limited by the process of content analysis. In some domains, until recently, the items were not amenable to any useful feature extraction with content-based filtering (such as movies, music, restaurants). Even for text documents, the representations capture only certain aspects of the content, and there are many others that would influence a user's experience, for example, in how far it matches the user's taste (Balabanovic, 2000).

Collaborative filtering is an approach to overcome this limitation. The basic concept of CF is to automate social processes such as "word of mouth." In everyday life, people rely on the recommendations from other people either by word of mouth, recommendation letters, and movie and book reviews printed in newspapers. Collaborative filtering systems assist and augment this process and help people in making decisions.

There are two main drawbacks to using collaborative filtering: the sparsity of large user-item databases and the first-rater problem (Rashid et al., 2002). Sparsity is a condition when not enough ratings are available due to an insufficient amount of users or too few ratings per user. An example of sparsity is a travel agent Web site, which has

tens of thousands of locations. Any user on the system will not have traveled to even 1% of the locations (possibly thousands of locations). If a nearest-neighbour algorithm is used, the accuracy of any recommendation will be poor as a sufficient amount of peers will not be available in the user-item database. The first-rater problem is exhibited when a new user is introduced that has not enough ratings. If no ratings have been given for an item or a new user has not expressed enough opinions, choices, or ratings, no predictions can be made due to the insufficient data available or bad recommendations will be made. In contrast, content-based schemes are less sensible to sparsity of ratings and the first-rater problem since the performance for one user relies exclusively on his or user profile and not on the number of users in the system.

Hybrid Filtering

Both content-based and collaborative filtering have disadvantages that decrease the performance and accuracy of the systems that implement them. If these methods are combined, then the drawbacks of one technique can be counteracted by the techniques of the other, and vice versa. There have been various implementations such as the following.

- By making collaborative recommendations, we can use others' experiences as a basis rather than the incomplete and imprecise content-analysis methods.
- By making content recommendations, we can deal with items unseen by others.
- By using the content profile, we make good recommendations to users even if there are no other users similar to them. We can also filter out items.
- We can make collaborative recommendations between users who have not rated any of the same items (as long as they have rated similar items).
- By utilizing group feedback, we potentially require fewer cycles to achieve the same level of personalisation.

User Profiles

In information filtering, a user's needs are translated into preference data files called user profiles. These profiles represent the users' long-term information needs (Kuflik & Shoval, 2000). The main drawbacks of using user profiles are creating a user profile for multiple domains and updating a user profile incrementally. The user profile can be populated by one or more of the following.

- *Explicit profiling*: This type of profiling allows users to let the Web site know directly what they want. Each user entering the site will fill out some kind of online form that asks questions related to a user's preferences (Eirinaki & Vazirgiannis, 2003). The problem with this method is the static nature of the user profile once it has been created. The stored preferences in the user profile cannot take into account the changing user's preferences.
- *Implicit user profiles*: This type of user profiles is created dynamically by tracking the user's behaviour pattern through automatic extraction of user preferences using some sort of software agent, for example, intelligent agents, Web crawlers, and so forth (Eirinaki & Vazirgiannis, 2003). All these usage statistics are correlated into a usage history that is an accurate interaction between the user and the system. This usage history is then analysed to produce a user profile that portrays the user's interests. The user profile can be updated every time the user starts a new session, making implicitly made profiles dynamic. The downside of this method is that the user initially will have to navigate and explore the site before enough data can be generated to produce an accurate profile.

Table 1. Multimedia information filtering

	Description	Techniques Used	Advantages	Disadvantages	Future R&D
Information Filtering	filtering a dynamic information space using relatively stable user requirements	SDI systems recommender systems	allows user to constantly receive content they are interested in with minimal user effort	does not support ad hoc queries that are dynamic compared to the information space they are searching (information retrieval)	all of the below
Content-Based Filtering	filtering content from a data stream based on extracting content features that have been expressed in a content-based user profile	vector space model probabilistic/inference models latent semantic indexing	objective analysis of large and/or complicated (e.g., multimedia) sources of digital material without much user involvement	1. content dependent 2. hard to introduce serendipitous recommendations as approach suffers from "tunnel vision" effect	extracting semantics from the structure of the content automatically without human intervention
Collaborative Filtering	filtering items based on similarities between target user's collaborative profile and peer users/ group	same as above	1. content independent 2. proves more accurate than content-based filtering for most domains of use enables introduction of serendipitous choices	1. sparsity: poor prediction capabilities when new item is introduced to database due to lack of ratings 2. new user: poor recommendations made to new users until they have enough ratings in their profiles for accurate comparison to other users	solving the sparsity and new-user problem finding other types of ratings schemes that do not use comparisons between users tastes (e.g., filtering using users temperament)
Hybrid Filtering	combines two or more filtering techniques	simple or rule based stereotype collaborative content based	to reduce weak points and promote strong points of each of the techniques used	weak points can outweigh strong points if the hybrid is created naively	using hybrid systems in domains where using one technique presents a large disadvantage/problem
User Profiles	log file containing user's preferences for consumption of content	content-based profiles collaborative profiles	1. user does not need to state preferences each and every time they use the system 2. user can maintain and update preferences with minimal effort compared to ad hoc methods	needs frequent updating or user preferences become stagnant	user profiles that are as ubiquitous and pervasive as the devices/systems that use them standardisation

continued on following page

Table 1. continued

Explicit User Profiles	user manually creates user profile by means of a questionnaire	questionnaires ratings	preference information gathered is usually of high quality	requires a lot of effort from user to update	collecting new user preferences that reduces user effort
Implicit User Profiles	system generates user profile from usage history of interactions between user and content	machine learning algorithms	minimal user effort required easily updateable by automatic methods	initially requires a large amount of interaction between user and content before an accurate profile is created	new machine learning algorithms for better accuracy when creating implicit user profiles
Hybrid User Profiles	combination of user profile techniques used to create a profile	explicit/implicit user profiles	to reduce weak points and promote strong points of each of the techniques used	N/A	finding effective strategies for deployment and use of hybrid profiles

- *Hybrid of implicit and explicit profiling*: The drawbacks of explicit and implicit profiling can be overcome by combining both methods into a hybrid. This allows the strong points of one technique to counteract the shortcomings of the other and vice versa. The hybrid method works by collecting the initial data explicitly using an online form. This explicitly created data is then updated by the implicit tracking method as the user navigates around the site. This is a more efficient method over both pure methods. In some instances, this hybrid method is reversed and the implicit tracking methods are used initially to produce a profile.
- *Stereotype profiling*: This can be achieved by data mining and analysis of usage histories over a period of visits. This provides accurate profiling for existing users with legacy data that is accurate. The disadvantage of this method is that it suffers from the same static nature as explicit profiling as the profile is created from archive data that might be obsolete, and therefore some updating might be necessary. The predefined user stereotype is a content-based user profile that has been created for a virtual user or group of users who have common usage and filtering requirements for consumption of certain material. The stereotyped profile will contain additional information about the stereotyped user such as demographic and social attributes. This additional information is then used to place new users to stereotyped profiles that match similar demographic and social traits. The new user without the need of any implicit or explicit tracking automatically inherits preference information.

FUTURE TRENDS

Content-based filtering in multimedia information filtering has one innate problem that researchers

are trying to solve: How can we extract semantics automatically from structural content of the model? In collaborative filtering, the age-old problem of sparsity and the new-user problem are still the biggest hindrances to using this method of filtering. Sparsity is being solved presently by hybrid systems, and it appears that this will be favoured way of dealing with sparsity (Lin & McLeod, 2002). The most promising solutions appear to be collaboratively filtering, standardised content-based profiles, which allow flexibility for systems to use either pure content-based or collaborative filtering, or a hybrid of both interchangeably.

Current work on user profiles focuses on improving creation techniques such as improved machine learning algorithms that create implicit user profiles more rapidly so that they can be more reliable and accurate in a shorter amount of time. For explicit user profiling, there is the work on selecting items that increase the usefulness of initial ratings that we have already discussed. The main way forward here, though, appears to be hybrid user profiles that are initially explicitly created and then implicitly updated.

With the advent of digital television and broadband, consumers will be faced with a deluge of multimedia content available to them at home and at work. What they will require are autonomous, intelligent filtering agents and automated recommender systems that actively filter information from multiple content sources. These personalisation systems can then collaborate to produce ranked lists of recommendations for all purposes of information the user might require. The key to this kind of service is not in the implementation of these systems or the way they are designed, but rather on a standard metadata language that will allow systems to communicate without proprietary restrictions and aid in end-user transparency in the recommendation process.

CONCLUSION

In the coming years, as nearly all communication and information devices become digital, we will see the development of systems that will be able not only to recommend items of interest to us, but will be able to make minor decisions for us based on our everyday needs such as ordering basic shopping groceries or subscribing to entertainment services on an ad hoc basis. What is required is a model of the user that describes the user's preferences for a multitude of characteristics that define the user's information needs. This model can then be used to filter data and recommend information based on this complete view of the user's needs. This has been done for many years with text files using techniques such as content-based and collaborative filtering, but has always been a problem with multimedia as the content is diverse in terms of storage, analysis techniques, and presentation. In recent years, classical techniques used for text filtering have been transferred and used in the area of multimedia information filtering. New developments such as hybrid filtering and improved metadata languages have made filtering multimedia documents more reliable and closer to becoming a real-world application.

KEY TERMS

Collaborative Filtering: Aims at exploiting preference behaviour and qualities of other persons in speculating about the preferences of a particular individual.

Content-Based Filtering: Organizes information based on properties of the object of preference and/or the carrier of information.

Hybrid Filtering: A combination of filtering techniques in which the disadvantages of one type of filtering is counteracted by the advantages of another.

Information Filtering: Filtering information from a dynamic information space based on a user's long-term information needs.

Recommendation: A filtered list of alternatives (items of interest) that support a decision-making process.

Recommender Systems: Assist and augment the transfer of recommendations between members of a community.

User profile : a data log representing a model of a user that can be used to ascertain behaviour and taste preferences.

INTRODUCTION

In the late 1990s, the availability of powerful computing capability, large storage devices, high-speed networking and especially the advent of the Internet, led to a phenomenal growth of digital multimedia content in terms of size, diversity and impact. As suggested by its name, "multimedia" is a name given to a collection of multiple types of data, which include not only "traditional multimedia" such as images and videos, but also emerging media such as 3D graphics (like VRML objects) and Web animations (like Flash animations). Furthermore, multimedia techniques have been penetrating into a growing number of applications, ranging from document-editing software to digital libraries and many Web applications. For example, most people who have used Microsoft Word have tried to insert pictures and diagrams into their documents, and they have the experience of watching online video clips, such as movie trailers. In other words, multimedia data have been in every corner of the digital world. With the huge volume of multimedia data, finding and accessing the multimedia documents that satisfy people's needs in an accurate and efficient manner became a non-trivial problem. This problem is defined as multimedia information retrieval.

The core of multimedia information retrieval is to compute the degree of relevance between users' information needs and multimedia data. A user's information need is expressed as a query, which can be in various forms, such as a line of free text like, "Find me the photos of George

Washington"; a few key words, like, "George Washington photo"; or a media object, like a picture of George Washington. Moreover, the multimedia data are also represented by a certain form of summarization, typically called an index, which is directly matched against queries. Similar to a query, the index can take a variety of forms, including key words and features such as color histograms and motion vectors, depending on the data and task characteristics.

For textual documents, mature information retrieval (IR) technologies have been developed and successfully applied in commercial systems such as Web search engines. In comparison, the research on multimedia retrieval is still in its early stage. Unlike textual data, which can be well represented by key words as an index, multimedia data lack an effective, semantic-level representation (or index) that can be computed automatically, which makes multimedia retrieval a much harder research problem. On the other hand, the diversity and complexity of multimedia offer new opportunities for its retrieval task to be leveraged by the state of the art in various research areas. In fact, research on multimedia retrieval has been initiated and investigated by researchers from areas of multimedia database, computer vision, natural language processing, human-computer interaction and so forth. Overall, it is currently a very active research area that has many interactions with other areas.

In the following sections, we will overview the techniques for multimedia information retrieval and review the applications and challenges in this area. Then, future trends will be discussed. Some important terms in this area are defined at the end of this article.

MULTIMEDIA RETRIEVAL TECHNIQUES

Despite the various techniques proposed in literature, there exist two major approaches to multimedia retrieval; namely, text-based and content-based. Their main difference lies in the type of index: The former approach uses text (key words) as the index, whereas the latter uses low-level features extracted from multimedia data. As a result, they differ from each other in many other aspects, ranging from feature extraction to similarity measurement.

Text-Based Multimedia Retrieval

Text-based multimedia retrieval approaches apply mature IR techniques to the domain of multimedia retrieval. A typical text-IR method matches text queries posed by users with descriptive key words extracted from documents. To use the method for multimedia, textual descriptions (typically key word annotations) of the multimedia objects need to be extracted. Once the textual descriptions are available, multimedia retrieval boils down to a text-IR problem. In early years, such descriptions were usually obtained by manually annotating the multimedia data with key words (Tamura & Yokoya, 1984). Apparently, this approach is not scalable to large datasets, due to its labor-intensive nature and vulnerability to human biases. There also have been proposals from computer vision and pattern recognition areas on automatically annotating the images and videos with key words based on their low-level visual/audio features (Barnard, Duygulu, Freitas, Forsyth, Blei, D. & Jordan, 2003). Most of these approaches involve supervised or unsupervised machine learning, which tries to map low-level features into descriptive key words. However, due to the large gap between the multimedia data form (e.g., pixels, digits) and their semantic meanings, it is unlikely to produce high-quality key word annotations automatically. Some of the systems are semi-automatic, attempting to propagate key words from a set of initially annotated objects to other objects. In other applications, descriptive key words can be easily accessible for multimedia data. For example, for images and videos embedded in

Web pages, the text surrounding them is usually a good description, which has been explored in the work of Smith and Chang (1997).

Since key word annotations can precisely describe the semantic meanings of multimedia data, the text-based retrieval approach is effective in terms of retrieving multimedia data that are *semantically relevant* to the users' needs. Moreover, because many people find it convenient and effective to use text (or key words) to express their information requests, as demonstrated by the fact that most commercial search engines (e.g., Google) support text queries, this approach has the advantage of being amenable to average users. But the bottleneck of this approach is still on the acquisition of key word annotations, since there are no indexing techniques that guarantee both efficiency and accuracy if the annotations are not directly available.

Content-Based Multimedia Retrieval

The idea of content-based retrieval first came from the area of content-based image retrieval (CBIR) (Flickner, Sawhney, Niblack, Ashley, Huang, Dom, Gorkani, Hafner, Lee, Petkovic, Steele & Yanker, 1995; Smeulders, Worring, Santini, Gupta & Jain, 2000). Gradually, the idea has been applied to retrieval tasks for other media types, resulting in content-based video retrieval (Hauptmann et al., 2002; Somliar, 1994) and content-based audio retrieval (Foote, 1999). The word "content" here refers to the bottom-level representation of the data, such as pixels for bitmap images, MPEG bit-streams for MPEG-format video and so forth. Content-based retrieval, as opposed to a text-based one, exploits the features that are (automatically) extracted from the low-level representation of the data, usually denoted as low-level features since they do not directly capture the high-level meanings of the data. (In a sense, text-based retrieval of documents is also "content based," since key words are extracted from the content of documents.) The low-level features used for retrieval depend on the specific data type: A color histogram is a typical feature for image retrieval, motion vector is used for video retrieval, and so forth. Despite the heterogeneity of the features, in most cases, they can be transformed into feature vector(s). Thus, the similarity between media objects can be measured by the distance of their respective feature vectors in the vector space under certain distance metrics. Various distance measures, such as Euclidean distance and M-distance, can be used as the similarity metrics. This has a correspondence to the vector-based model for (text) information retrieval, where a bag of key words is also represented as a vector.

Content-based retrieval also influences the way a query is composed. Since a media object is represented by its low-level feature vector(s), a query must be also transformed into a feature vector to match against the object. This results in query-by-example (QBE) (Flickner et al., 1995), a new search paradigm where media objects such as images or video clips are used as query examples to find other objects similar to them, where "similar" is defined mainly at perceptual levels (i.e., looks like or sounds like). In this case, feature vector(s) extracted from the example object(s) are matched with the feature vectors of the candidate objects. A vast majority of content-based retrieval systems use QBE as its search paradigm. However, there are also content-based systems that use alternative ways to let users specify their intended low-level features, such as by selecting from some templates or a small set of feature options (i.e., "red," "black" or "blue").

The features and similarity metrics used by many content-based retrieval systems are chosen heuristically and are therefore ad-hoc and unjustified. It is very questionable that the features and metrics are optimal or close to optimal. Thus, there have been efforts seeking for theoretically justified retrieval approaches whose optimality is guaranteed under certain circumstances. Many of these approaches treat retrieval as a machine-learning problem of finding the most

effective (weighted) combination of features and similarity metrics to solve a particular query or set of queries. Such learning can be done online in the middle of the retrieval process, based on user-given feedback evaluations or automatically derived "pseudo" feedback. In fact, relevance feedback (Rui, Huang, Ortega & Mehrotra, 1998) has been one of the hot topics in content-based retrieval. Off-line learning has also been used to find effective features/weights based on previous retrieval experiences. However, machine learning is unlikely to be the magic answer for the content-based retrieval problem, because it is impossible to have training data for basically an infinite number of queries, and users are usually unwilling to give feedback.

Overall, content-based retrieval has the advantage of being fully automatic from the feature extraction to similarity computation, and thus scalable to real systems. With the QBE search paradigm, it is also able to capture the perceptual aspects of multimedia data that cannot be easily depicted by text. The downside of content-based retrieval is mainly due to the so-called "semantic gap" between low-level features and the semantic meanings of the data. Given that users prefer semantically relevant results, content-based methods suffer from the low precision/recall problem, which prevents them from being used in commercial systems. Another problem lies in the difficulty of finding a suitable example object to form an effective query if the QBE paradigm is used.

APPLICATIONS AND CHALLENGES

Though far from mature, multimedia retrieval techniques have been widely used in a number of applications. The most visible application is on Web search engines for images, such as the Google Image search engine (Brin & Page, 1998), Ditto.com and so forth. All these systems are text-based, implying that a text query is a better vehicle of users' information need than an example-based query. Content-based retrieval is not applicable here due to its low accuracy problem, which gets even worse due to the huge data volume. Web search engines acquire textual annotations (of images) automatically by analyzing the text in Web pages, but the results for some popular queries may be manually crafted. Because of the huge data volume on the Web, the relevant data to a given query can be enormous. Therefore, the search engines need to deal with the problem of "authoritativeness" – namely, determining how authoritative a piece of data is – besides the problem of relevance. In addition to the Web, there are many digital libraries, such as Microsoft Encarta Encyclopedia, that have the facilities for searching multimedia objects like images and video clips by text. The search is usually realized by matching manual annotations with text queries.

Multimedia retrieval techniques have also been applied to some narrow domains, such as news videos, sports videos and medical imaging. NIST TREC Video Retrieval Evaluation has attracted many research efforts devoted to various retrieval tasks on broadcast news video based on automatic analysis of video content. Sports videos, like basketball programs and baseball programs, have been studied to support intelligent access and summarization (Zhang & Chang, 2002). In the medical imaging area, for example, Liu et al. (2002) applied retrieval techniques to detect a brain tumor from CT/MR images. Content-based techniques have achieved some level of success in these domains, because the data size is relatively small, and domain-specific features can be crafted to capture the idiosyncrasy of the data. Generally speaking, however, there is no killer application where content-based retrieval techniques can achieve a fundamental breakthrough.

The emerging applications of multimedia also raise new challenges for multimedia retrieval technologies. One such challenge comes from the new media formats emerged in recent years, such as Flash animation, PowerPoint file and Synchro-

nized Multimedia Integration Language (SMIL). These new formats demand specific retrieval methods. Moreover, their intrinsic complexity (some of them can recursively contain media components) brings up new research problems not addressed by current techniques. There already have been recent efforts devoted to these new media, such as Flash animation retrieval (Yang, Li, Liu & Zhuang, 2002a) and PowerPoint presentation retrieval. Another challenge rises from the idea of retrieving multiple types of media data in a uniform framework, which will be discussed next.

FUTURE TRENDS

In a sense, most existing multimedia retrieval methods are not genuinely for "multimedia," but are for a specific type (or modality) of non-textual data. There is, however, the need to design a real "multimedia" retrieval system that can handle multiple data modalities in a cooperative framework. First, in multimedia databases like the Web, different types of media objects coexist as an organic whole to convey the intended information. Naturally, users would be interested in seeing the complete information by accessing all the relevant media objects regardless of their modality, preferably from a single query. For example, a user interested in a new car model would like to see pictures of the car and meanwhile read articles on it. Sometimes, depending on the physical conditions, such as networks and displaying devices, users may want to see a particular presentation of the information in appropriate modality(-ies). Furthermore, some data types, such as video, intrinsically consist of data of multiple modalities (audio, closed-caption, video images). It is advantageous to explore all these modalities and let them complement each other to obtain a better retrieval effect. To sum, a retrieval system that goes across different media types and integrates multi-modality information is highly desirable.

Informedia (Hauptmann et al., 2002) is a well-known video retrieval system that successfully combines multi-modal features. Its retrieval function not only relies on the transcript generated from a speech recognizer and/or detected from overlaid text on screen, but also utilizes features such as face detection and recognition results, image similarity and so forth. Statistical learning methods are widely used in Informedia to intelligently combine the various types of information. Many other systems integrate features from at least two modalities for retrieval purpose. For example, the WebSEEK system (Smith & Chang, 1997) extracts key words from the surrounding text of images and videos in Web pages, which is used as their indexes in the retrieval process. Although the systems involve more than one media type, typically, textual information plays the vital role in providing the (semantic) annotation of the other media types.

Systems featuring a higher degree of integration of multiple modalities are emerging. More recently, MediaNet (Benitez, Smith & Chang, 2002) and multimedia thesaurus (MMT) (Tansley, 1998) are proposed, both of which seek to provide a multimedia representation of a semantic concept – a concept described by various media objects including text, image, video and so forth – and establish the relationships among these concepts. MediaNet extends the notion of relationships to include even perceptual relationships among media objects.

Yang, Li and Zhuang (2002b) propose a very comprehensive and flexible model named *Octopus* to perform an "aggressive" search of multi-modality data. It is based on a multi-faceted knowledge base represented by a layered graph model, which captures the relevance between media objects of any type from various perspectives, such as the similarity on low-level features, structural relationships such as hyperlinks and semantic relevance. Link analysis techniques can be used to find the most relevant objects for any given object in the graph. This new model can accommodate

knowledge from various sources, and it allows a query to be composed flexibly using either text or example objects, or both.

CONCLUSION

Multimedia information retrieval is a relatively new area that has been receiving more attention from various research areas like database, computer vision, natural language and machine learning, as well as from industry. Given the continuing growth of multimedia data, research in this area will expectedly become more active, since it is critical to the success of various multimedia applications. However, technological breakthroughs and killer applications in this area are yet to come, and before that, multimedia retrieval techniques can hardly be migrated to commercial applications. The breakthrough in this area depends on the joint efforts from its related areas, and therefore, it offers researchers opportunities to tackle the problem from different paths and with different methodologies.

KEY TERMS

Content-Based Retrieval: An important retrieval method for multimedia data, which uses the low-level features (automatically) extracted from the data as the indexes to match with queries. Content-based image retrieval is a good example. The specific low-level features used depend on the data type: Color, shape and texture features are common features for images, while kinetic energy and motion vectors are used to describe video data. Correspondingly, a query also can be represented in terms of features so that it can be matched against the data.

Index: In the area of information retrieval, an "index" is the representation or summarization of a data item used for matching with queries to obtain the similarity between the data and the query, or matching with the indexes of other data items. For example, key words are frequently used indexes of textual documents, and color histogram is a common index of images. Indexes can be manually assigned or automatically extracted. The text description of an image is usually manually given, but its color histogram can be computed by programs.

Information Retrieval (IR): The research area that deals with the storage, indexing, organization of, search, and access to information items, typically textual documents. Although its definition includes multimedia retrieval (since information items can be multimedia), the conventional IR refers to the work on textual documents, including retrieval, classification, clustering, filtering, visualization, summarization and so forth. The research on IR started nearly half a century ago and it grew fast in the past 20 years with the efforts of librarians, information experts, researchers on artificial intelligence and other areas. A system for the retrieval of textual data is an IR system, such as all the commercial Web search engines.

Multimedia Database: A database system dedicated to the storage, management and access of one or more media types, such as text, image, video, sound, diagram and so forth. For example, an image database such as Corel Image Gallery that stores a large number of pictures and allows users to browse them or search them by key words can be regarded as a multimedia database. An electronic encyclopedia such as Microsoft Encarta Encyclopedia, which consists of tens of thousands of multimedia documents with text descriptions, photos, video clips and animations, is another typical example of a multimedia database.

Multimedia Document: A multimedia document is a natural extension of a conventional textual document in the multimedia area. It is defined as a digital document composed of one or multiple media elements of different types (text, image, video, etc.) as a logically coherent unit. A multimedia document can be a single picture or a single MPEG video file, but more often it is a complicated document, such as a Web page, consisting of both text and images.

Multimedia Information Retrieval (System): Storage, indexing, search and delivery of multimedia data such as images, videos, sounds, 3D graphics or their combination. By definition, it includes works on, for example, extracting descriptive features from images, reducing high-dimensional indexes into low-dimensional ones, defining new similarity metrics, efficient delivery of the retrieved data and so forth. Systems that provide all or part of the above functionalities are multimedia retrieval systems. The Google image search engine is a typical example of such a system. A video-on-demand site that allows people to search movies by their titles is another example.

Multi-Modality: Multiple types of media data, or multiple aspects of a data item. Its emphasis is on the existence of more than one type (aspects) of data. For example, a clip of digital broadcast news video has multiple modalities, include the audio, video frames, closed-caption (text) and so forth.

Query-by-Example (QBE): A method of forming queries that contains one or more media object(s) as examples with the intention of finding similar objects. A typical example of QBE is the function of "See Similar Pages" provided in the Google search engine, which supports finding Web pages similar to a given page. Using an image to search for visually similar images is another good example.

Chapter 1.21
Multimedia Capture, Collaboration and Knowledge Management

Subramanyam Vdaygiri
Siemens Corporate Research Inc., USA

Stuart Goose
Siemens Corporate Research Inc., USA

ABSTRACT

This chapter presents methods and technologies from Siemens Corporate Research that can assist in the process of creating multimedia collaborative knowledge bases: capture, querying, visualization, archiving, and reusability of multimedia knowledge bases. A selection of Siemens products in the healthcare and communication domains are introduced, above which novel multimedia collaboration and knowledge management technologies have been developed by the authors. With examples, it is explained how in concert these technologies can contribute to streamlining the processes within healthcare enterprises, telemedicine environments and home healthcare practices.

INTRODUCTION AND MOTIVATION

The networked healthcare enterprise is providing unprecedented opportunities for healthcare workers to collaborate and make clinical decisions in an efficient manner. Significant progress has been made to enable healthcare personnel to obtain answers to simple clinical questions by using medical databases of evidence-based answers. This approach allows reuse and sharing of knowledge to help healthcare professionals to save time and effort and help patients in an efficient manner. For situations where healthcare workers have simple questions with simple answers, this approach is perhaps overkill. However, when the questions are of a more complex nature, by capturing and archiving complex answers in a rich multimedia form they can be exploited multiple in the future

to explain solutions in a manner that can be easily digested by healthcare workers.

A contemporary healthcare enterprise involves complex media elements (images, videos, documents, etc.) and volumes of documentation both digital and on paper. The healthcare knowledge base should incorporate these media elements and easily allow users to search, extract, and reuse. Some of the modern knowledge management systems allow building of communities of practice around documents. But there is a need to move beyond regular office documents to address rich media and encompass specialized medical and clinical data.

The networked enterprise is also enabling a plethora of ways for healthcare personnel to communicate and collaborate. The next generation of communication technologies will bring converged voice and data solutions on a single network. This is helping integrate the healthcare IT (Information Technology) systems with Web-based communications. In recent years we have witnessed a proliferation of communication and data devices like GPRS cellular phones and PDAs, thus providing an opportunity for accessing clinical information anywhere/anytime and allowing users to collaborate over clinical information to reach decisions quickly.

The concept of presence and availability offered by various instant messaging tools is changing the manner in which people are communicating with each other. *Presence* enables a user to know who in their contact or buddy list is available or not at any given point in time. *Availability* options allow a user to signal whether they are available to be contacted and which form of communication they favor. Presence and availability information allow users to interact in various ways in offline, real-time or in near-real time modes. Mobile communication technologies are being developed that enables mobile location and presence. The integration of the healthcare enterprise content repository with a Web-based infrastructure and presence and availability represent the three pillars of modern unified, or converged, communication.

Although the potential for a rich communications and IT infrastructure is high, there remains a need to streamline the communications and collaborations between healthcare personnel to ensure that valuable knowledge gained from daily interactions between healthcare personnel is not lost. This chapter presents methods and technologies from Siemens Corporate Research that can assist in the process of creating multimedia collaborative knowledge bases: capture, querying, visualization, archiving, and reusability of multimedia knowledge bases. Throughout the chapter, a number of Web-based technologies are introduced that enable healthcare personnel to interact in a variety of modes regardless of whether they are mobile or sedentary.

BACKGROUND: STREAMLINING HEALTHCARE AND TELEHEALTH

Since the advent of Web-based workflows, there has been a growing emphasis in healthcare enterprises on methods to increase organizational efficiencies, reduce errors and focus on patient care. One such platform is Soarian (Siemens Soarian) from Siemens Medical (Siemens Medical) that offers an integrated workflow technology that can streamline the operational processes of healthcare. Soarian's infrastructure has been engineered based on clinical processes that enable physicians to focus less on administrative duties and more care by providing them with access to all clinical data in a single view. The goals being to offer actionable guidelines to clinicians based on best practices and to support them in reaching accurate, evidence-based decisions promptly.

A nascent area for which technology can be a significant enabler is that of telemedicine (Hibbert, Mair, May, Boland, O'Connor, Capewell, & Angus, 2004), where clinical needs are extended beyond the boundary of the hospital. A key re-

quirement to facilitate a telehealth consultation is to have medical personnel in remote locations to communicate and collaborate with each other in a quick, efficient, and effective manner.

Some of the issues that an integrated communications and healthcare medical IT infrastructure can help address are:

- Reducing time and effort wasted in daily communications (paging, phone calls) between clinicians, nurses, and patients
- Reducing the communication pathways by a combined infrastructure can streamline how users can be reached at a given point in time
- Complex solutions to questions can be assembled in multimedia fashion to succinctly convey the message
- Knowledge exchanged and gained from daily interactions between people can captured and archived with high granularity
- Reuse, by querying and retrieving relevant segments from past collaborative activities, can avoid recreating the wheel when a recurrent problem reappears
- Reduce paper work by having one consolidated IT-communications infrastructure
- Reduce cost by managing a single converged voice and data network

Remote communications in contemporary telehealth systems allows users to collaborate in two different modes: store & forward and in real time. The asynchronous mode, or store & forward method, allows for the sharing of medical information in an offline mode, but the absence of human interactivity prevents healthcare personnel from augmenting this with personal comments, insight and knowledge. The real time collaboration mode requires the session to be scheduled in advance, and all participants must be dedicated to the collaboration session for the duration.

The current mode of document/data sharing involves all users within telehealth WAN (Wide Area Network) cluster to upload documents, data and code to a central repository from where other users can extract materials of interest. This mode of collaboration among users is not sufficient for many users to exchange complex ideas and viewpoints regarding various images and other documents in intricate detail. For example, medical researchers frequently need to locate and reference information that is not only physically distributed across the sites of their collaborators, but also in an array of formats (images, reports generated based on experiments, or code execution).

Often users collaborate by exchanging e-mail messages along with data/documents downloaded from a central Web server. Although this allows individuals to participate at their own pace, users invest much time typing descriptive text to discuss a particular topic, especially when expressing complex thoughts within context of a document or image. The problem becomes particularly acute when users are collaborating using document attachments. This mode leads to large documents being exchanged as attachments back and forth between users, with the potential for inconsistencies to arise between successive versions. Moreover, with clinicians collaborating across time zones on documents or images, a need has been observed for conveying complex information via rich multimedia.

To anticipate and streamline the future communication and IT needs of healthcare enterprises and burgeoning telehealth market, the various requirements were distilled:

- **Communication**: It is clear that there exists a need to combine communications within the healthcare processes to optimize the clinicians' time to manage better the inexorable stream of phone calls, paging, exchange of paper and digital documents. Presence-based communications enables the healthcare personnel to communicate in a very effective manner.

- **Collaboration:** The tools should provide a consistent manner to collaborate irrespective of the mode, all online in a real time conference, or a single user making her analysis and comments on an image in offline mode. By allowing users to collaborate in different modes within a browser-based environment on diverse medical data can facilitate a seamless collaboration workflow. These technologies can enhance typical telemedicine scenarios and also extend conventional doctor-patient interactions to include web-based interactions such as chronic care or follow-ups.
- **Knowledge Management**: There should also be a consistent way to archive the multimedia annotations made on such documents. This would not only allow researchers to collaborate based on their time and schedule, but also to search, retrieve and filter all comments and analysis made previously by collaborators on any multimedia document.

The remaining sections describe ongoing efforts at Siemens Corporate Research to develop technological solutions driven by these anticipated future needs.

TECHNOLOGICAL BUILDING BLOCKS

OpenScape (Siemens OpenScape) from Siemens Communications Networks (Siemens Information and Communications Networks) is a suite of communication applications designed to increase the productivity of information workers. It aims to control the panoply of communication applications and devices, on both fixed and wireless networks, connected via local and wide area networks. OpenScape addresses the fragmented nature of communication modalities and their separation and provides a unifying framework for integrating, managing and streamlining communication in the enterprise.

It obviates redundant communication sessions, where a person calls multiple phone numbers and/or leaves duplicate voice, email, and instant messages in an effort to communicate urgent issues. Hence, it is possible to avoid:

- Unnecessary cell phone intrusions into client meetings, work sessions or personal time;
- Wasted time setting up conference calls, communicating call-in information, sending and synchronizing documents, and establishing separate sessions for voice, Web and video collaboration; and
- The difficulty of mobilizing all key colleagues that may be equipped with different applications, or because setting up a collaborative session is too complex and time consuming.

It provides healthcare personnel the experience of a single, synchronized set of communication resources, sharing common controls and shared communication rules and intelligence. These capabilities can be accessed via a wide range of devices and interfaces to serve the constantly changing needs of mobile employees. OpenScape provides personal and workgroup communications portals for multiple healthcare domains. OpenScape makes extensive use of presence-based communication. There are different ways of showing presence and the user's status:

Device Presence: indicates the presence of an application or communications device. The user could be online or off-line. For example:

- Off hook/on hook status of an IP desk phone or mobile phone
- Instant Messaging (IM) application presence
- Collaboration application presence indicating whether an individual has signed on to the application or not
- On which terminal can the user be reached

User Presence: associates presence with an individual rather than the user's device

- The willingness of the user to be reached
- The activity that the user is currently engaged
- The location of the user—working remotely, out of office, and so on.
- Mood—happy, good or bad tempered or even annoyed

Device presence or terminal status will become less important as terminals become more advanced and intelligent, with the ability to handle a multitude of multimedia content adaptively. A mobile phone or PDA, for instance will be able to negotiate with the remote communication party the type of information it can support, for instance video, audio, and so on.

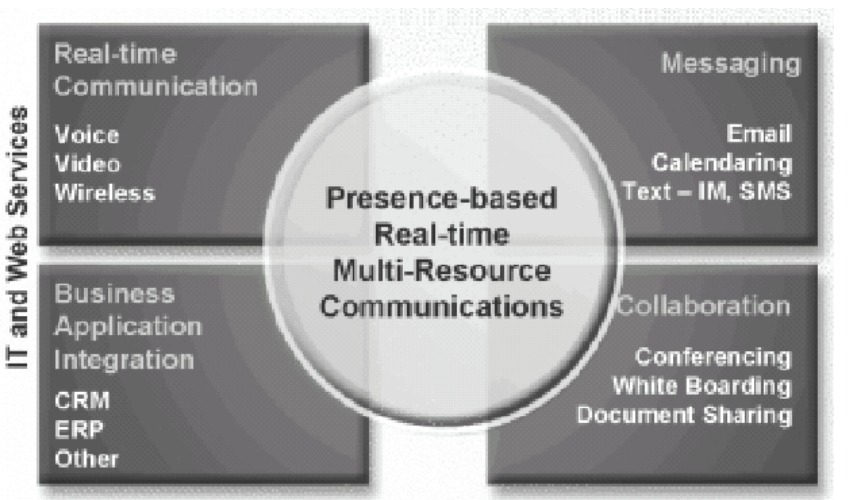
IMS (Siemens IMS) from Siemens Communications Mobile (http://www.siemens-mobile.com) provides new presence and communications platform for mobile devices and networks. The IMS platform was standardized for new multimedia applications and services that could be rapidly deployed by mobile network operators, such as audio/video conferencing, chat, and presence services over new mobile devices. Moreover, IMS is positioned to voice and multimedia communication. Different from the legacy circuit-switched voice/data communication in regular phone calls, IMS is based on IP technology that can control real-time and non-real-time services on the same IP network.

Together OpenScape, IMS and Soarian provide the core technological building blocks that enable the integration of the healthcare enterprise content repository with a Web-based infrastructure and presence and availability. Our research work is layered above these three pillars and the following sections illustrate the benefits of a converged communication healthcare enterprise.

ENRICHING COLLABORATIVE CONSULTATIONS

During a telehealth consultation between patient and clinician various medical documents might be used including laboratory reports, photos of injury/skin lesions, x-rays, pathology slides, EKGs, MR/CT images, medical claim forms, prescriptions, clinical results, case reports, and other documents. Some of the documents like photos and images

Figure 1. OpenScape: A way of communication



might have been captured using camera during patient visits, while other clinical (lab reports) or financial information (insurance claim) were gleaned from other information systems. Face-to-face video conferencing is commonly used in telemedicine not only for personalized remote communications, but also for regulatory reasons as evidence of a consultation the costs for which can subsequently be reimbursed.

It would be convenient if a clinician could combine, interface, convert, and extract disparate medical information such as those listed above from peripheral devices like photo cameras, video conferencing session, content management systems, PACS, and regular office documents into a Web-based *composite* document. Thereafter, it would be convenient if this composite document could be used as the basis for browser-based collaboration (whether it is offline or real time) between various participants. Such a composite document generated should combine all relevant information needed for a particular collaboration session into one seamless document so that effective offline or real time collaboration can occur.

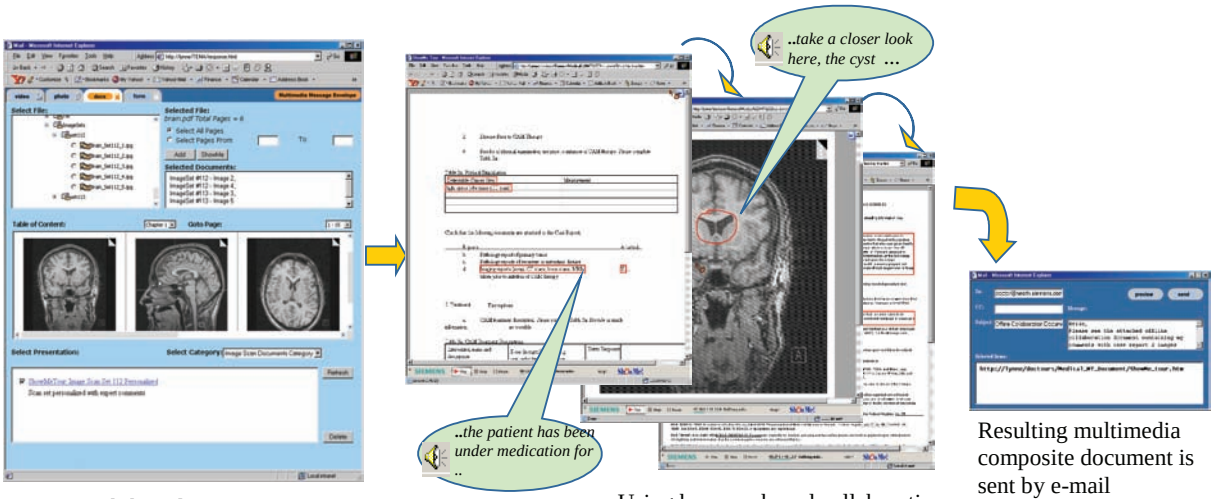
Let us now look at some of the details involved in realizing our solution. A user could choose specific pages from document(s) stored locally and automatically have the selected pages converted to HTML format and hyperlinked with each other to form a composite document. Then, he or she could highlight important parts of the document and add personal comments with the help of voice and graphic annotations using our multimedia presentation software, called *ShowMe* (Sastry, Lewis, & Pizano, 1999). The multimedia annotation technology developed is unique as it not only captures the spatial nature but also the temporal aspects. For instance, the multimedia annotation on a document would capture a synchronized temporal voice, graphic and mouse pointer annotations. Finally, the user could save the composite document along with the annotations on the local web server, and this document is referred to as the collaboration document. Associated with this collaboration document is some metadata in the form of an XML schema that describes this document. This metadata is finally uploaded to the central server and its URL on this central server can then be sent to other participants.

Participants can view the collaboration document via the URL of the metadata stored on the central Web server using a lightweight Web-browser player. As the collaboration documents are stored locally, they are amenable to document management tasks, including deleting, moving, and so on. However, any such document management task must be accompanied by making an appropriate change in the metadata located at the central Web server. The above process allows various users to collaborate over documents quickly and easily by only sharing information relevant to the topic in question. In addition, there is increase in productivity as users can quickly exchange information without having to exchange e-mail to explain problem/solution.

Figures 2, 3, and 4 show a particular workflow implemented to demonstrate the spectrum of modes of browser-based collaboration using office documents and Web content. The components can be re-used in several other collaboration workflows and processes. As only specific parts of different documents might be needed for a particular collaborative session, participants are able to combine, on the fly, specific pages from several documents with different formats into one seamless Web-based composite document. Using synchronous voice and graphic annotations along with mouse as a pointer, a clinician can continuously narrate a patient's case history across the entire composite document while using the mouse to gesture or annotate on different parts of the aggregated document.

These modes of collaboration—whether offline, IM-based, or real-time—take place using a regular web browser with the requisite collaboration plug-ins. This allows the participants to collaborate within the familiar environment

Figure 2. Multimedia Enhanced Store & Forward Collaboration: A clinician can quickly create one seamless web-based composite multimedia document by combining various medical information segments like images, photos, EKGs together. Synchronous voice, graphic and mouse annotations can then be easily added on top of the composite document before sending it via regular e-mail. The recipient needs only a web browser to view the composite document along with the voice and graphic annotations.



Web-based Composite Document Creation

Using browser based collaboration tools, the user narrates and annotates

Resulting multimedia composite document is sent by e-mail

Figure 3. Instant Messaging Based Document Collaboration: This uses presence and availability of different participants to setup collaboration. Also, this allows asynchronous messaging of voice and graphic annotations within a real-time collaboration session. This enables users to exchange information at one's own pace and yet participate in a near real-time collaboration session.

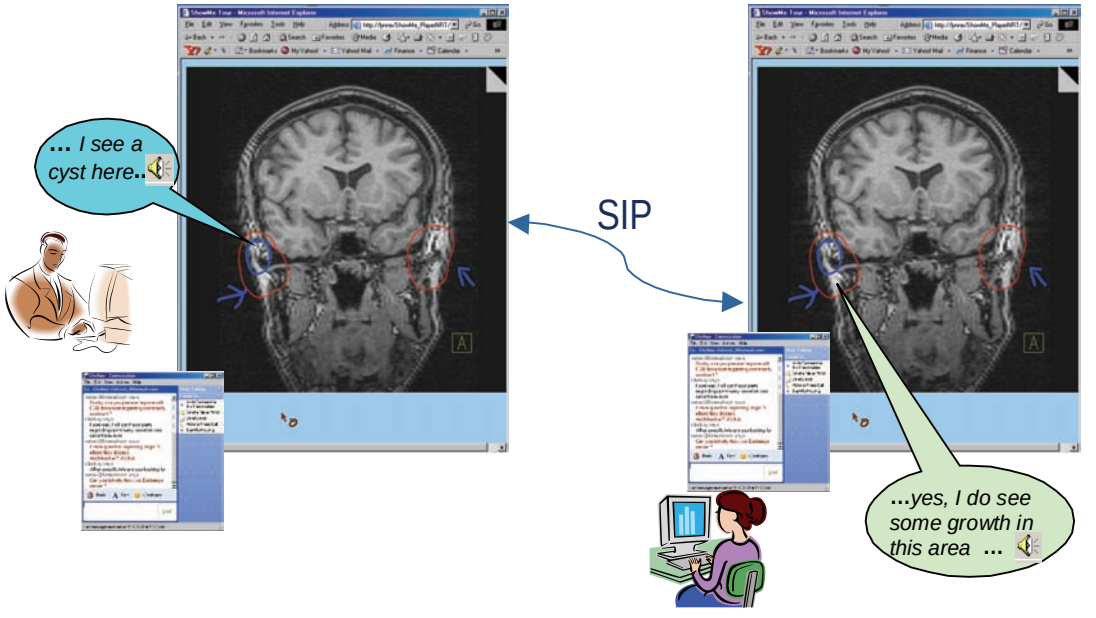


Figure 4. Multi-participant Real-Time Collaboration: Several remote participants using their web browser can collaborate on the generated composite medical document. The collaboration is accompanied by a voice conference.

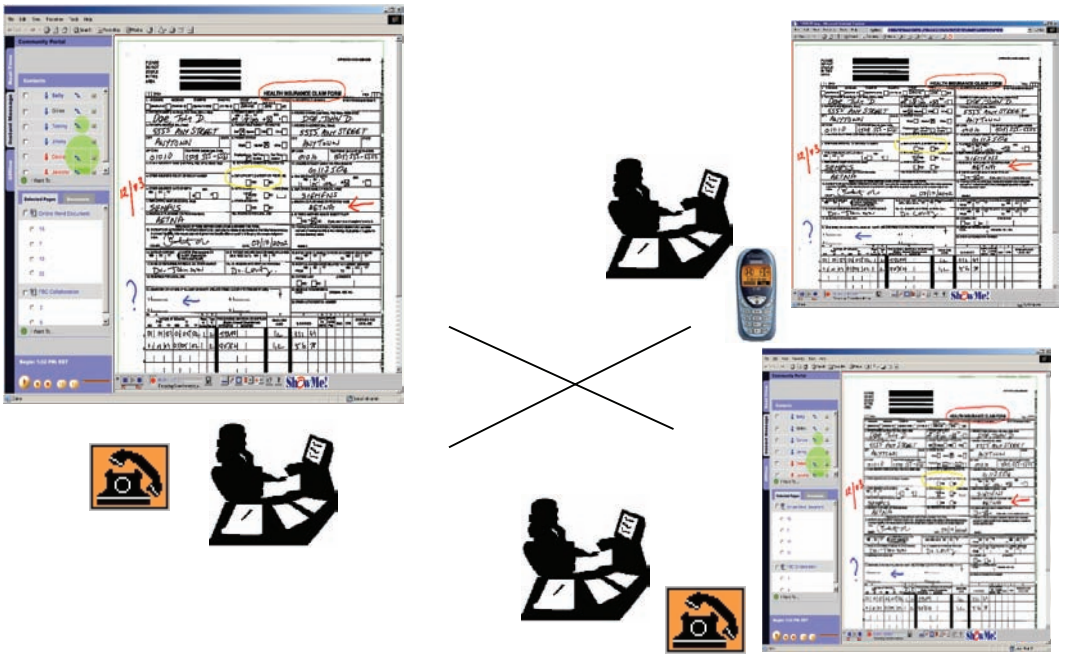


of a Web browser. The annotations by various participants during a collaboration session on composite medical documents can be archived into a database in a very lightweight manner. The voice and graphic annotations along with the composite document can be archived with high granularity along with meta-data describing the various annotations. This would allow for searching and retrieval of not only medical information/documents exchanged during collaboration sessions, but also to obtain information regarding comments, interactions and dialogue between various participants. For instance, one can query and retrieve specific comments/annotations made by particular participant from a past collaboration session on a specific medical document. In addition, one can easily follow the changes in the medical condition of the patient by comparing the medical documents and associated annotations made during successive patient visits.

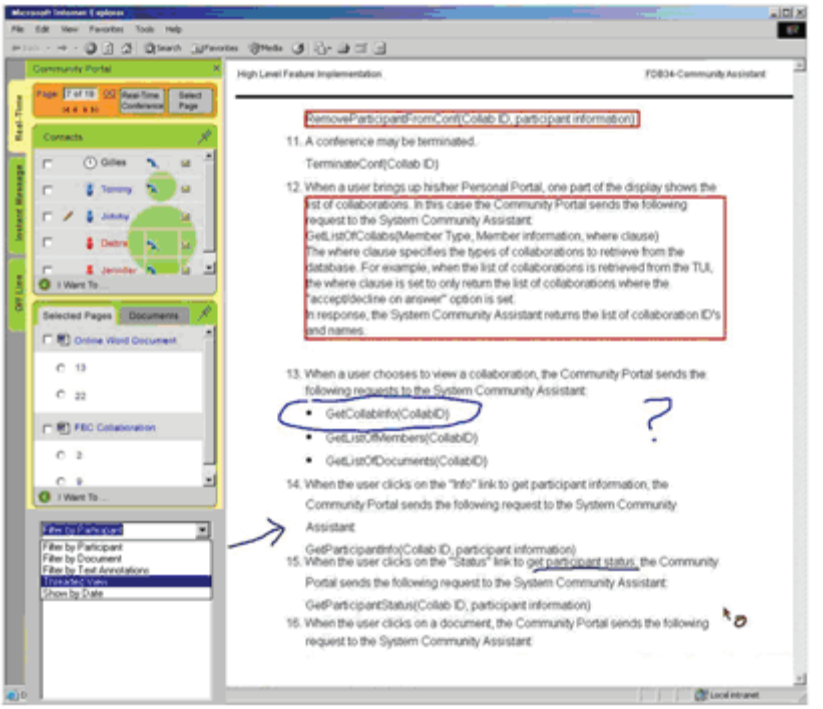
COLLABORATION KNOWLEDGE ACCESS AND MANAGEMENT

Access to and the management of the knowledge contained within the collaboration documents introduced above is reviewed in this section.

Filtering Collaboration Annotations

The ability to save annotations from a real time, offline or IM based document collaboration enables participants to filter and view a conference in several different ways. The figure below illustrates how an archived conference may be viewed in different ways by applying different filters. For example, the filters can be to show the conference view by participants, by documents collaborated on, by threaded view, by type of annotations, by session, and so on. New filters can be easily created based on the use case scenario.

Figure 5. The clinician can filter and quickly access specific segments from past collaborative sessions and reuse to address the current problem.



Navigation, Access and Reusability of Knowledge Documents

The ability to archive annotations (both temporal and spatial) allows the users to retrieve and reuse segments of existing annotated documents from any mode of collaboration. For example, during a real time conference, several participants collaborated on different composite pages (where the composite pages might have come from different original documents). A user can select a particular page from an existing collaboration document, filter annotations based on any criteria (as described above), add any more composite pages, add more temporal/spatial annotations and collaborate in off-line, IM, or real time mode. This allows the enterprise to preserve the knowledge gathered during several collaboration sessions performed in any mode, while still enabling users to select parts of annotated documents from previous sessions for further reuse in future collaboration sessions.

Multimedia Response and Discussion Boards

The structure of the collaboration archive allows one user to respond to any particular comment or annotation made by another user. The response could be in the form of a temporal or spatial annotation, or both. One scenario is that a sender can compose a composite document, make his or her annotations and send to the recipient(s). The annotated document could be sent as an attachment, or accessed from a central server. In the latter case, the annotated document is sent as a URL link. The recipient(s) can overlay their replies (annotations) and send back the annotated document, or the annotated document can be further annotated by other users (forwarding via e-mail.) By quickly overlaying temporal or spatial annotations it allows users to imbue information and temporal context to their responses.

Figure 6. A multimedia threaded discussion board

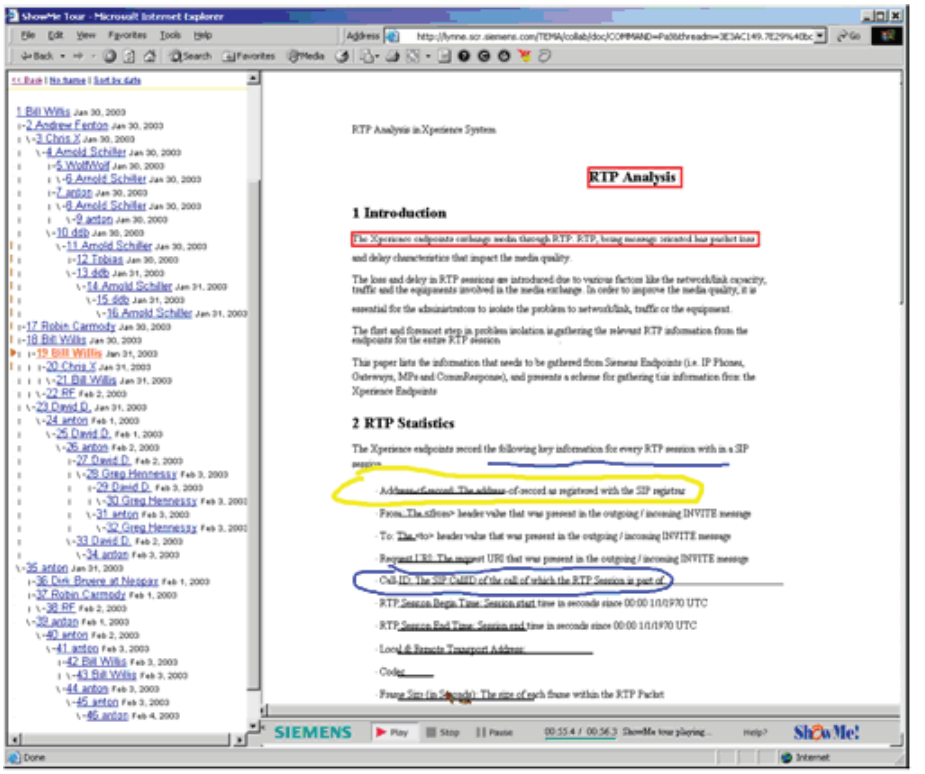


Figure 6 shows document(s) being collaborated upon by several users in different collaboration modes using a threaded approach. These annotations could have been made in offline mode by different users or some of the annotations could have happened in a real time or IM conference and then imported into the discussion thread. For example, a user creates a composite document, adds various annotations in offline mode and sends it to her workgroup. The workgroup meets later and discusses in real time conference mode where annotations are captured as temporally with high granularity. During the real-time conference, they add more composite pages and perform collaborations above them. When finished, one user adds the resulting composite document with the temporal and spatial annotations to the discussion group. Subsequently, participants can add/edit/delete more comments (or annotations), or respond to any particular comment—hence a rich threaded discussion is facilitated. This scenario illustrates how group of users can work in a newsgroup discussion manner and leverage rich multimedia to express their thoughts.

Query and Retrieval of Multimedia Knowledge Base

As reported in the previous sections, the collaboration archive of interactions—voice, graphic, text, or mouse pointer annotations—between participants over several documents in different collaboration modes being captured and archived in a structured manner over time. As knowledge in the form of annotations is captured and reused in high granularity, there is a need for a simple search mechanism to locate appropriate segments of annotated documents from a large archive of annotated composite documents.

Queries to the knowledge base can be based on various criteria, for example, using metadata captured during collaboration session, the annotations using voice, text and the document content, and also by using feature relative annotations one can get the textual content of the document on which annotations were overlaid.

Representation, Visualization and Browsing of Collaborations

To leverage the knowledge contained within archived collaboration sessions, we have also explored various approaches for representing, visualizing and browsing archived collaboration sessions. As collaborations often involve two dimensional documents and are by nature temporal, we are investigating representing the structure and content of collaborations in a three dimensional space. Arguably the most prevalent standard in the 3D graphics arena is VRML: a high-level textual language for describing the geometry and behavior of 3D scenes. Fortunately, a plethora of browser plug-ins are readily available. Following an iterative design/evaluation cycle, we converged on the design of a single VRML model with an interface that embodied and combined many of the characteristics that we sought:

- A viewpoint providing a visual overview/ summary of the session
- A viewpoint providing a detail view of the session
- Interactivity and browsing capabilities at both overview and detail levels

Figures 7 and 8 show two viewpoints on the same VRML model, with each viewpoint having a distinct purpose.

The viewpoint shown in Figure 8 conveys the structure of the session (three topics were discussed), the documents used in the course of the discussion (indicated by the thumbnail icons on the right of the timeline), and that two action items were assigned (the red columns on the right of the timeline).

The viewpoint shown in Figure 8 exposes more detail regarding the content of the session. An audio waveform running along the timeline illustrates the presence of noise and is also color-indexed to the participants. An exploded view of the current document under discussion is show in the middle of the visualization. A small portrait image of the current speaker is shown in the corner of the current document, along with an icon that can be clicked on to initiate a phone call, e-mail, or instant message to that person. In addition, red columns along the left side of the timeline indicate assigned action items with a portrait image of the person responsible.

A VCR metaphor is provided to assist with navigation, and a VCR control panel can be seen at the right of the interface. When the play button is activated, the exploded view of the current

Figure 7. A visual overview of a session that conveys structure, documents used, and action items assigned

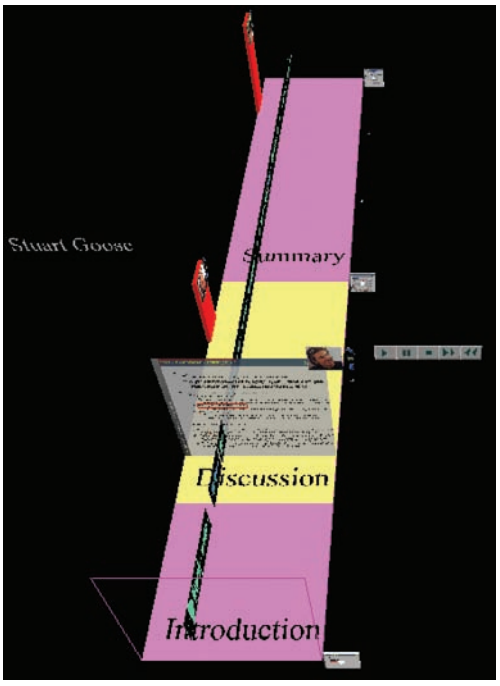

Figure 8. The detail view of a session

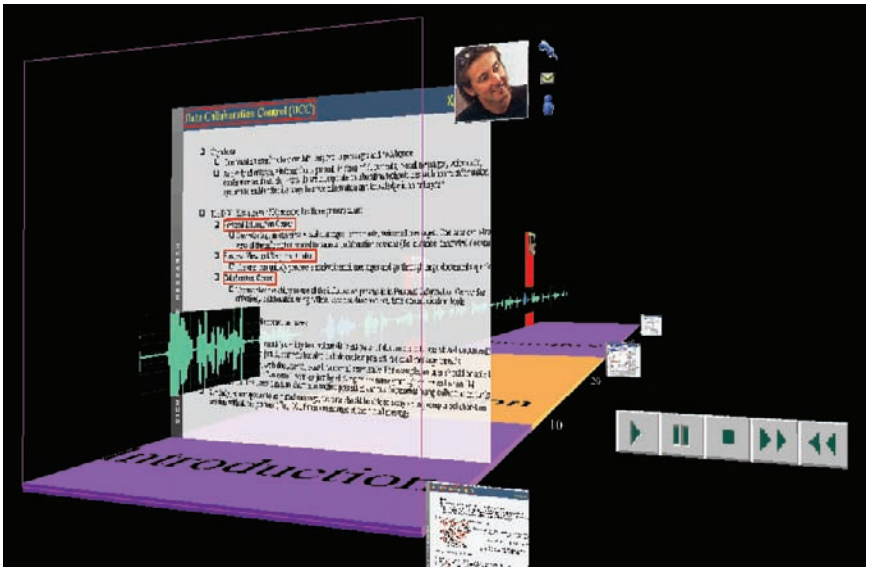

document begins to glide backwards through time in synchrony with the audio stream played at normal speed. The forward and rewind buttons move the current position to the beginning of the respective session topic.

IN SUPPORT OF HOME HEALTH: NOMADIC NURSE

Home healthcare nursing is an increasingly widespread type of healthcare that typically involves a nurse driving to a patient's place of residence to provide the necessary monitoring and treatment. There are a wide variety of cases in which home healthcare is recommended by physicians, and recent years have seen a steady increase in the need for this type of care (Giles, 1996). While many industry observers believe home healthcare will increase in the future, many current home healthcare providers are either non-profit agencies or operate with conservative profit margins. In addition, as nurses' time is a scarce resource and IT spending limited, any new technologies that are not economically priced or that require nurses to increase the time spent with patients have a high probability of being passed over or abandoned.

Home healthcare nursing is by nature a peripatetic profession, and as such nurses need to transport their equipment from one home to the next. From our studies described previously, it was observed that the preponderance of nurses used paper and pencil notes augmented by their memory to record the interactions with their patients throughout their working day. The written and memorized notes were entered into the computer-based system upon their return home or to the office. There were a plethora of reasons as to why some nurses chose to operate in this mode. For example, some asserted that anything that breaks the contact between the clinician and the patient breaks the treatment involved in the visit. "There is a healing involved in the physical touch between the nurse and the patient" was the expression used. To avoid breaking this important connection, the application would need to use less obtrusive techniques that still provide for sterile-hands operation. In addition, the application would need to integrate well with the nurses'

workflow and their frequent need for non-linear information access.

Hardware and Software Selection

The hardware selection was influenced by the following factors:

- Laptops were identified as the device of choice for the majority of home healthcare clinicians interviewed during the study. Lowering costs of laptops make them relatively affordable even for low-budget agencies; lightweight of the devices is appropriate in context of patient visits.
- The study revealed that clinicians were open to the idea of using a PDA for reasons of size, weight, and no boot-up latency. However, concern was expressed as to whether the screen size would be adequate for their needs.
- New government regulations (HIPPA) place significant emphasis on ensuring secure access to sensitive patient information in order to preserve patient privacy. Towards satisfying the HIPPA regulations, a Siemens biometric mouse was incorporated (Siemens Biometric Mouse).
- To reduce the impact of the interaction upon the nursing tasks, a discreet wireless Bluetooth earpiece was incorporated. This enables the nurse to issue spoken commands, but also to receive spoken feedback without the patient hearing. The absence of wires was crucial so as not to inhibit the nursing duties.

The software technology selection was influenced by the following factors:

- Clinicians may access the application from a variety of different locations, including the office, their homes, patient homes, from the car while driving, etc.
- Administering clinical care requires sterile conditions, which makes traditional input devices unsuitable. This requirement indicates a multimodal interface (Multimodal Interaction Working Group), which, if necessary, can be controlled entirely by voice.
- Home healthcare practitioners would prefer continuous access to the patient database, however the existing wireless coverage of rural areas remains too fragmented to be reliable. The application needs to be able to work in either offline or online modes of connectivity.

Collectively, these requirements led us to conclude that a WWW-based solution was feasible, and that recent advances in multimodal technologies provide support on various devices. As such, the user interface was developed using a combination of HTML, Java and Javascript.

Notebook Design: Capturing Patient Vital Signs

The goal of our prototype is to show how cost-effective technology can be integrated into the workflow of a nurse to prove that patient vital signs can be captured unobtrusively. If successful, this could obviate the need for the nurse to enter this data into a computer system upon returning to the office.

In order to address the majority of agencies that expressed interest in notebook and PDA platforms, our design sought to offer a similar user experience while attempting to leverage the respective advantages of each. To provide hands-free operation, the nurse's notebook computer is equipped with a Bluetooth (Bluetooth) capability. Bluetooth wireless headset (Bluetooth headset from Siemens) supports mobile speech interaction with the application within an adequate radius. The initial implementation was developed for a notebook, as seen in Figure 9.

As can be seen from Figures 10 and 11, a multimodal interface allows the nurse to use the keyboard/mouse and/or speech to navigate and enter values into the visualization. For the laptop, SALT (SALT Forum) was selected as the technology used to develop the multimodal interface. In the classical SALT paradigm, speech recognition is initiated using either a keyboard or a mouse, but to offer truly hands-free operations we introduced some novel approaches to support continuous recognition and pause/resume functionality. This enables nurses to use verbal commands to indicate to the application that they are about to start dictating commands, or whether they are engaged in the conversation with a patient. Additionally, after temporarily deactivating the speech recognition, the nurse can resume working by simply issuing a voice command.

Figure 9. Nurse's laptop, Bluetooth PCMCIA card and Bluetooth enabled headset

PDA Design: Less is More

The notebook implementation was heavily leveraged for the subsequent implementation for the Pocket PC PDA. While the functionality was preserved, the HTML was simplified and modified for appropriate consumption and interaction on the PDA form factor, as can be seen in Figure 12.

Although SALT technology can be demonstrated using a Pocket PC PDA, the speech processing is not performed locally on the mobile device but redirected to a server machine on the LAN. While this is not practical for deployment, it enabled us to experiment with the approach. It is anticipated that speech processing on the PDA will become available in the near future.

Figure 10. While taking measurements from the patient, the nurse can speak the clinical measurements via the Bluetooth enabled headset directly into the HTML form

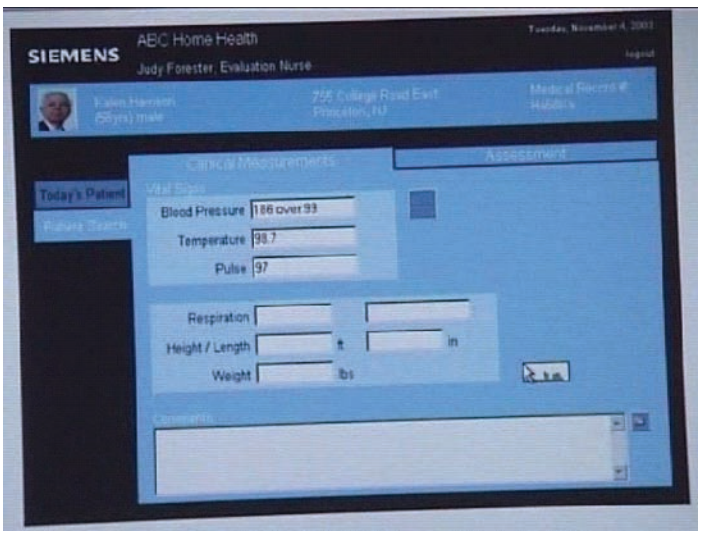

Figure 11. While interviewing the patient, the nurse can speak the diagnosis and functional assessment data via the Bluetooth enabled headset directly into the HTML form

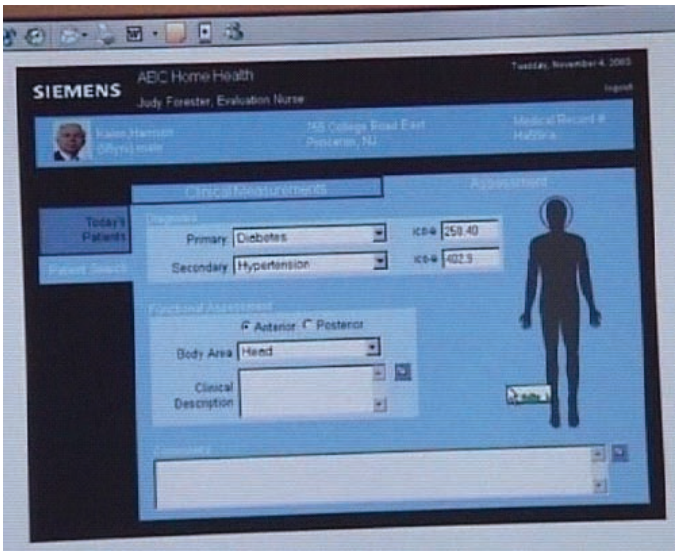

Figure 12. Leveraging handwriting recognition to capture vital signs into an HTML form

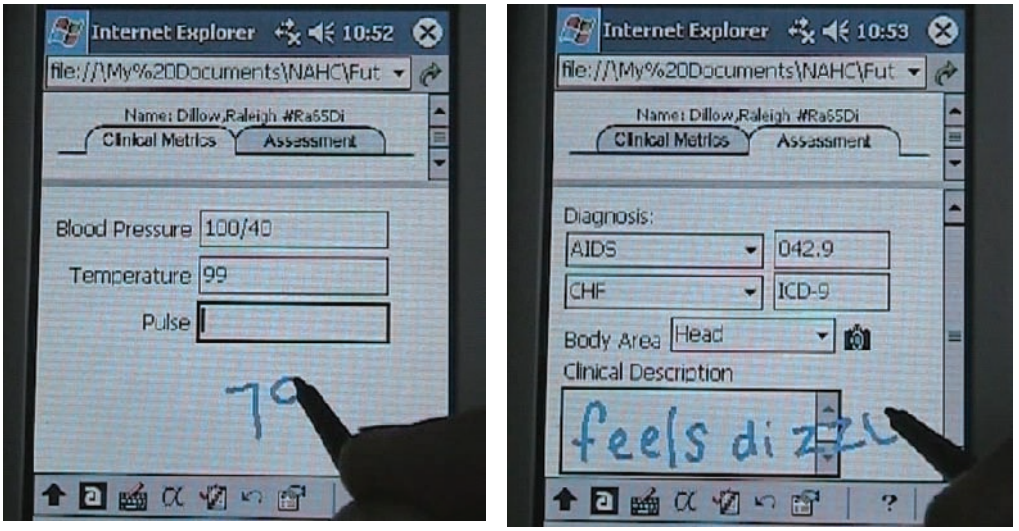
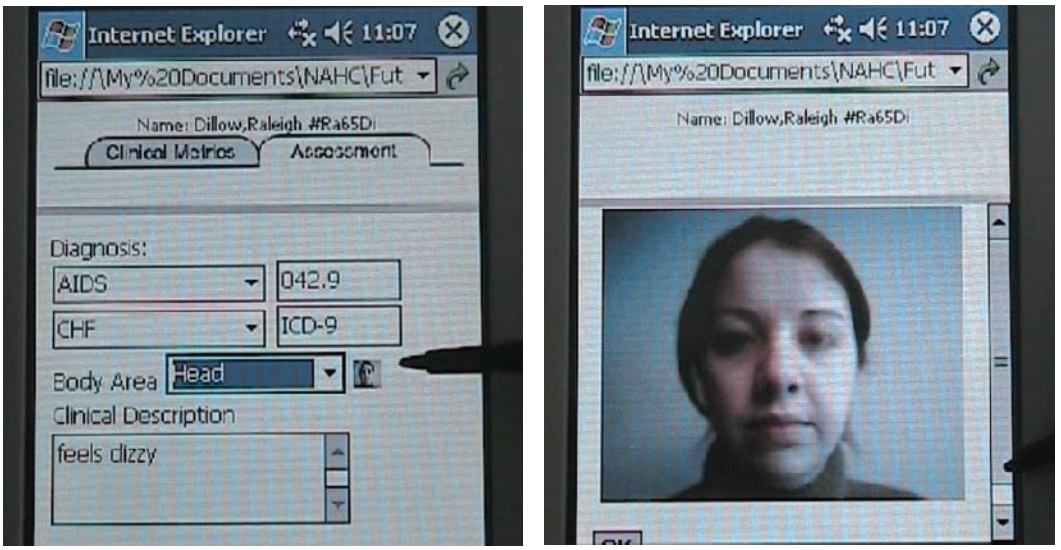


Speech is not the most appropriate input mechanism for every occasion, but one tool in the palette of a multimodal interface designer. As many of the nurses that we studied rely on paper and pencil to record patient notes, we sought to exploit handwriting recognition technology as a means to harness this activity and increase nurses' productivity by capturing this text and entering in directly into HTML form fields. This approach can be seen in Figure 12.

In our interviews we found that the old adage of a picture capturing a thousand words is not lost on nurses. Hence, we sought to offer in our prototype the seamless support for capturing

Figure 13. Convenient image capture is seamlessly integrated into the patient record

Figure 14. A thumbnail icon of the captured image can simply be clicked-on for closer inspection



images and integrating them directly into the patient information. A small and inexpensive digital camera peripheral connected via the SDIO port can be used for this purpose. The process of capture, abstraction through a thumbnail representation, and the viewing of the image can be seen in Figures 13 and 14.

In addition to capturing an image, it is often desirable to be able to augment an image with a synchronized audio commentary and associated pen markings to describe specific aspects of the patient's condition. Hence, a multimedia annotation capability is offered that can support this requirement and be stored along with the patient record.

Current and future work includes conducting formal user studies with nursing practitioners from two home healthcare agencies to evaluate the usability and efficacy of the devices and approaches described above to inform the subsequent iteration of the prototype design.

CONCLUSIONS

The manner in which a networked enterprise can facilitate a plethora of ways for healthcare personnel to communicate and collaborate was explored within this chapter. The next generation of communication technologies augurs well for converged voice and data solutions on a single network. We anticipate a closer union between healthcare IT systems and web-based communications. Technology innovation has spawned a proliferation of communication and data devices, such as GPRS cellular phones and PDAs, and with it a significant opportunity for accessing clinical information anywhere, anytime, allowing healthcare practitioners to collaborate upon clinical information and reach conclusions more effectively.

Throughout the chapter a selection of technologies has been presented that can enable healthcare personnel to interact in a variety of styles. These approaches demonstrated how multimedia technologies can be harnessed to capture information and enable users to collaborate in range of modes in an effective manner. It was also described how the knowledge captured during collaboration interactions can be saved and archived for future search, reference and reusability. In addition, technology support for home healthcare nurses is presented that shows potential for streamlining the capture and entry of information into the patient record.

ACKNOWLEDGMENTS

The authors would like to thank our team members at Siemens Corporate Research for their contributions to the technologies described.

Chapter 1.22
Multimedia Systems and Content-Based Image Retrieval

Sagarmay Deb
University of Southern Queensland, Australia

ABSTRACT

In this chapter, we present a basic introduction of the two very important areas of research in the domain of information technology, namely, multimedia systems and content-based image retrieval. The latter is still a widely unresolved problem. We discuss some of the works done so far in content-based image retrieval in the context of multimedia systems.

INTRODUCTION

Research on multimedia systems and content-based image retrieval has gained tremendous momentum during the last decade. This is due to the fact that multimedia databases cover the text, audio, video and image data which help us to receive enormous amounts of information and which has brought fundamental changes in our life style. Content-based image retrieval (CBIR) is a bottleneck of the access of multimedia databases simply because there remains vast differences in the perception capacity between a human being and a computer. We give an introduction of these two areas in this chapter along with an idea of the research being conducted in CBIR over the last few years in the context of multimedia systems. The section on multimedia databases describes general background of multimedia databases. The section on Content-based image retrieval talks about general background, problems and some of the works done so far in content-based image retrieval. A summary is presented at the end.

MULTIMEDIA DATABASES

General Background

Multimedia environment, much talked-about topic in computers, is adding new dimensions in the area of information technology and all relevant fields. Multimedia and imaging applications are enriching existing applications by integrating images, voices, text and video. The ultimate goal is to have all information types digitized and computerized. As we proceed to convert enormous amounts of non-digitized information into multimedia

objects, the outcomes are extremely significant with its effects in various activities of life.

The available literature talks about certain advanced technologies which are:

- Computer-aided design and manufacturing (CAD/CAM) using 2-D and 3-D graphics, animation and visualization
- Network standard, such as asynchronous transfer mode (ATM) and fibre distributed data interface (FDDI) which allow multimedia information to flow through wide area networks (WANS) as well as local area networks (LANS)
- Image processing systems which include more sophisticated techniques to segment and process images
- Character and object recognition systems using pattern recognition and neural networks
- Software systems such as object-oriented languages, databases and operating systems
- Hardware components such as video cameras, video boards, sound boards and high-resolution monitors
- Storage devices such as optical disks and magneto-optic technologies

All of the above developments in information technology are lending support to multimedia information technology.

Multimedia environments can be available in PC-based systems, then in more advanced Power PCs with built-in audiovisual capabilities and to more advanced and sophisticated UNIX workstations.

There are some similarities between object-oriented databases and multimedia databases. Just as an object-oriented database tries to depict the real world as much as possible so are multimedia databases because of their ability to capture and play back the sounds and images of the real world as realistically as possible.

Other features of multimedia databases are:

1. Automatic feature extraction and indexing where image processing and pattern recognition systems for images often extract the various features and content of multimedia objects. When large amounts of non-digitized information are converted into digital multimedia objects, quite a few automatic indexing features are utilized. This is particularly true where paper documents are converted into scanned digitized images that are eventually recognized by optical character recognition (OCR) products.
2. Interactive querying, relevance feedback and refining where user queries involve a graphical user interface where the construction of the query can be performed interactively. In multimedia databases, it is common to have domains or lists of various existing multimedia objects so that the user can construct a query interactively. The result of the query can be shown with more relevant selections first followed by less relevant selections and the user can select relevant objects, refine the query and resubmit, etc.
3. Content-based indexing where a video could contain the frame number of the start of each clip or scene for each video. For images containing objects arranged spatially, iconic indexing through 2-D strings contains the location and relative position of each element or object in the whole image.
4. Single and multikey (dimensional) indexing where spatial and multidimensional indexes are used. A geometric region has X and Y coordinates. Spatial indexes, such as R trees or multidimensional structures such as grid files or k-d trees will produce better access times for queries covering all the dimensions of the multidimensional attribute being retrieved.
5. Storage organization for Binary Large Objects (BLOB) where multimedia databases

allow the users to create and store BLOBs. Because the BLOB interfaces typically allow the user to access and update byte or bit streams, the multimedia storage manager makes use of the positional indexes to store the BLOBs. This permits very fast access to continuous streams of bytes or bits starting at a particular position. Positional indexes also accelerate the insertions and appends of byte streams in BLOBs.

6. Spatial data types and queries where the spatial relationships between various elements of the image are studied.
7. Query optimization where a multimedia database management system that integrates hierarchical storage optimization, information/content-retrieval modules and complex object managers must decide on the best way to perform execution.
8. Complex object clustering where to provide efficient access to a multimedia complex object, the storage management layer has to incorporate complex object clustering storage techniques. The goal would be to minimize I/O access time for the complex object and its sub-objects and also the processing time needed to reconstruct the complex object.

Multimedia Database Management Systems

Multimedia Database Management Systems (MDBMS) deal with audio, video, text and image data. We can create, update, delete and enquire these data in the multimedia databases. Ordinarily, data are BLOBS. Multimedia objects can take lot of storage space and that requires very efficient storage management systems for fast and efficient access of the data.

There are three layers in a multimedia database. The interface layer deals with browsing and query. Then, the object composition layer handles managing objects and the storage layer deals with clustering and indexing.

Research Issues

Some of the important research problems are: (1) watermarking technology, which is very useful in protecting digital data such as audio, video, image, formatted documents and three dimensional objects; (2) synchronization and timeliness, which are required to synchronize multiple resources like audio and video data; (3) quality of service (QoS), which is relevant to high-speed networks to achieve low end-to-end delay, loss rate and optimum data transmission with the available resources; and (4) reusability, where browsing of objects give the users the facility to reuse multimedia resources. (5) Since the multimedia data is voluminous and occupy a lot of storage space, developing efficient storage techniques is essential for fast accessing and retrieval of information. (6) For video content-based retrieval, efficient shot boundary detection, key frames selection, feature extraction and retrieval are important research issues at the moment.

CONTENT-BASED IMAGE RETRIEVAL

General Background

Images are being generated at an ever-increasing rate by various sources. They include military purposes, aviation satellites, biomedical purposes, scientific experiments and home entertainment.

Application areas in which CBIR is a principal activity are numerous and diverse. They are:

- Art galleries and museum management
- Architectural and engineering design
- Interior design
- Remote sensing and management of earth resources
- Geographic information systems
- Scientific database management
- Weather forecasting

- Retailing
- Fabric and fashion design
- Trademark and copyright database management
- Law enforcement and criminal investigation
- Picture archiving and communication systems (Gudivada & Raghavan, 1995)

Previously there were two approaches to CBIR.

The first one is the attribute-based representation advocated by database researchers where image contents are modeled as a set of attributes extracted manually and managed within the framework of conventional database management systems. Queries are specified using these attributes. This entails a high-level of image abstraction.

The second approach propagated by image interpretation researchers depends on an integrated feature-extraction/object-recognition subsystem to overcome the limitations of attribute-based retrieval. This subsystem automates the feature-extraction and object-recognition task that occurs when the image is inserted into the database. This automated approach to object recognition is computationally expensive, difficult and tends to be domain specific.

Recent CBIR research tries to combine both of the above mentioned approach and has given rise to efficient image representations and data models, query-processing algorithms, intelligent query interfaces and domain-independent system architecture.

There are two major categories of features. One is primitive, which is concerned with extracting boundaries of the image and the other one is logical, which defines the image at various levels of detail.

Regardless of which approach is used, the retrieval in CBIR is done by color, texture, sketch, shape, volume, spatial constraints, browsing, objective attributes, subjective attributes, motion, text and domain concepts (Gudivada & Raghavan, 1995).

Our study of the existing literature suggests, in recent times, there have been very many attempts to perform CBIR on an efficient basis based on feature, color, texture and spatial relations. Quite a few models have been developed which address the problem of image retrieval from various angles. Some of the models are QBIC (Query by Image Content), Virage, Pichunter, VisualSEEK, Chabot, Excalibur, Photobook, Jacob, and Digital Library Project (Seaborn, 1997).

One of the most well known packages is QBIC which was developed by IBM. It uses color, texture, shape, example images and sketches to retrieve images used in large image and video databases. Based on the same kind of approach developed by Virage which made use of color, composition (color layout), texture and structure (object boundary information) and is being applied in face recognition and in retrieval of ophthalmologic images. NEC Research Institute has developed Pichunter, which utilizes image properties like ratio of image dimensions, color percentages and global statistical and frequency properties. It is more applicable in database retrieval instead of feature detection and is also being applied in relevance feedback using Bayesian probability theory. VisualSEEK, developed at the Columbia University Centre for Telecommunication Research, uses color percentage method in content-based retrieval. Using regional colors and their relative locations, the image is segmented and this is quite a bit similar to the way we perceive an image. Chabot mainly uses texts to retrieve images. It uses to some extent color percentages to retrieve images automatically otherwise all features are input manually. Excalibur is of the same type as QBIC and Virage and uses standard metrics, color, shape and texture and like Pichunter uses image ratio. In addition, it extracts features like structure of brightness and color. It gives an option to the users to indicate which features are dominant. MIT's Vision and

Modeling Group developed Photobook, which uses color percentages, textures and statistical analysis. The images are segmented here and then texts are made out of those segmentations using predefined templates and techniques. The images are retrieved based on these texts. Jacob uses a combination of color, texture and motion as features to retrieve video clips as this package is developed for video databases. The Digital Library Project of Berkeley University applies color percentage method and feature of dots. The user can define the quantity of various colors in the image and also can define colors and sizes of dots to be there in the image.

These models have brought this area of CBIR from its infancy to a matured stage. They study the various features of the images, make statistical analysis of color distribution as well as shape and texture and retrieve images from the contents of the image.

The developments in this field have been defined in three levels (Eakins & Graham, 1999).

Level one is the primitive level where low-level features like color, texture, shape and spatial locations are used to segment images in image databases and then find symmetry based on these segmentations with the input image. Plenty of research projects were being done during the past decade. As we mentioned earlier, many software packages have been developed for efficient image retrieval. Most of them have used a combination of text-based and content-based retrieval. Images are segmented manually, a priory and text are generated based on these manual segmentations and retrievals are conducted accordingly. But since the volume of images generated could be enormous in fields like satellite picturing, this method of manual part processing is time-consuming and expensive. Few automatic retrievals without human intervention have been developed like QBIC, Virage, and Excalibur which are now commercially being used in addition to packages developed which are not yet commercial. But they have limited applications in areas like trademark registration, identification of drawings in a design archive or color matching of fashion accessories based on input image. No universally accepted retrieval technique has yet been developed. Also, the retrieval techniques developed without human intervention are far from perfect. Segmentation has been done in some packages based on color where the segmented parts taken individually do not contribute to any meaningful identification (Ma et al., n.d.). They generate a vague symmetry between input objects and objects in image database. This level still needs to be developed further to have universal applications.

Level two deals with bringing out semantic meanings of an image of the database. One of the best known works in this field is of Forsyth et al. (1996) successfully identifying human beings within images. This technique had been applied for other objects like horses and trees.

Also, for example, a beach can be identified if a search is based on color and texture matching and the color selected is wide blue with yellow texture below.

Attrasoft Image Finder has developed an image retrieval technique where input images would be stored in various files. Also, images would be kept in directory files. There is an interface screen where users can provide the file name containing the input image and also can put various parameters like focus, background, symmetry, rotation type, reduction type and so on. The images from the directory would then be retrieved based on these inputs. The images in the directory are defined containing the sample segments or translated segments, rotated segments, scaled segments, rotated and scaled segments, and brighter or darker segments. This method goes to some extent in bringing out semantic meanings in an image in the sense that the user can specify an input image semantically, then corresponding input image is retrieved and based on that input image, image database is searched to find symmetry (Attrasoft, 2001). There are few other similar automatic image retrieval models available including Computer Vision Online Demos.

But this level also needs a lot more developments to achieve a universally accepted technique to bring out semantic meanings out of the image.

Level three attempts retrievals with abstract attributes. This level of retrieval can be divided into two groups. One is a particular event such as 'Find pictures of Australia playing cricket against another particular country.' A second one could be 'Find a picture which is a residential area.'

To interpret an image after segmentations and analyzing it efficiently requires very complex reasoning. This also requires a retrieval technique of level two to get semantic meanings of various objects. It is obvious this retrieval technique is far from being developed with modern technology available in the field.

Works Done So Far

In this section, we present some of the works done in the field of content-based image retrieval. Although plenty of research works have been done so far in the field, no universally accepted model has yet been developed. The research concentrated on image segmentation based on low-level features like color, shape, texture and spatial relations. But to find the semantic meanings or high-level meanings of an image like whether it is the image of human beings or a bus or a train and so on is still a problem. Attempts are being made to link low-level and high-level features. But it is proving difficult for the very simple reason there remains a vast gap between human perception and computer perception. We present a few references of the works done.

One approach is where document images are accessed directly, using image and object attributes and the relative positions of objects within images, as well as indirectly, through associated document components. This is based on retrieving multimedia documents by pictorial content. Queries may address, directly or indirectly, one or more components. Indirect addressing involves references from associated components, e.g., an image caption is a text component referring to an image component and so is an in-text reference to an image. A symbolic image consists, in general, of objects, relations among objects and descriptions of object and image properties. The properties of objects and whole images are described by object and image attributes, respectively (Constantopoulos et al., 1991).

Then there is another method of querying and content-based retrieval that considers audio or visual properties of multimedia data through the use of MORE. In MORE, every entity in an application domain is represented as an object. An object's behavior is presented with a method, which activates the object by receiving a certain message. Objects bearing the same characteristics are managed as a single class. Generally, a class contains structural definitions, methods, or values that the objects in the class commonly posses (Yoshitaka et al., 1994).

Range searches in multi-dimensional space have been studied extensively and several excellent search structures have been devised. However, all of these require that the ranges in the different dimensions be specified independently. In other words, only rectangular regions can be specified and searched so far. Similarly, non-point objects can be indexed only in terms of their bounding rectangles. A polyhedral search of regions and polyhedral bounding rectangles can often provide a much greater selectivity in the search. How to use multi-attribute search structures for polyhedral regions, by mapping polyhedral regions into rectangular regions of a higher dimensions has been shown (Jagadish, 1990).

In human design processes, many drawings of shapes remain incomplete or are executed inaccurately. Cognitively a designer is able to discern these anomalous shapes, whereas current CAAD systems fail to recognize them properly so that CAAD systems are unable to match left-hand-side conditions of shape rules. As a result, current CAAD systems fail to retrieve

right-hand-side actions. Multi-layered neural networks are constructed to solve the recognition and transformation of ill-processed shapes in light of recent advances of connectionism in cognitive psychology and artificial intelligence (Liu, 1993).

Attempts have been made to retrieve a similar shape when shapes are measured by coordinate systems (Mehrotra & Gary, 1995).

Then, MIRO (Multimedia Information Retrieval) is researching new methods and techniques for information storage and retrieval so that all types of media can be handled in an integrated manner through adaptive interaction with a user. Topics include human-computer interaction, logical and probabilistic models of information retrieval, run-time support for multimedia information retrieval and evaluation of retrieval effectiveness (Thanos, 1995).

A parallel computing approach to creating engineering concept spaces for semantic retrieval has been developed through the Illinois Digital Library Initiative Project. This research presents preliminary results generated from the semantic retrieval research component of the Illinois Digital Library Initiative (DLI) project. Using a variation of the automatic thesaurus generation techniques, to which is referred to as the concept space approach, it is aimed to create graphs of domain-specific concepts (terms) and their weighted co-occurrence relationships for all major engineering domains. Merging these concept spaces and providing traversal paths across different concept spaces could potentially help alleviate the vocabulary (difference) problem evident in large-scale information retrieval. Experiments had been done previously with such a technique for a smaller molecular biology domain (Worm Community System, with 10+ MBs of document collection) with encouraging results (Chen et al., 1996).

A system named MARCO (denoting MAp Retrieval by COntent) that is used for the acquisition, storage, indexing and retrieval of map images is presented. The input to MARCO is raster images of separate map layers and raster images of map composites. A legend-driven map interpretation system converts map layer images from their physical representation to their logical representation. This logical representation is then used to automatically index both the composite and the layer images. Methods for incorporating logical and physical layer images as well as composite images into the framework of a relational database management system are described. Indices are constructed on both the contextual and the spatial data thereby enabling efficient retrieval of layer and composite images based on contextual as well as spatial specifications. Example queries and query processing strategies using these indices are described. The user interface is demonstrated via the execution of an example query. Results of an experimental study on a large amount of data are preserved. The system is evaluated in terms of accuracy and in terms of query execution time (Samet, 1996).

Fingerprint databases are characterized by their large size as well as noisy and distorted query images. Distortions are very common in fingerprint images due to elasticity of the skin. In this article, a method of indexing large fingerprint image databases is presented. The approach integrates a number of domain-specific high-level features such as pattern class and ridge-density at higher levels of the search. At the lowest level, it incorporates elastic structural feature-based matching for indexing the database. With a multilevel indexing approach, the search space is reduced. The search engine has also been implemented on Splash 2 — a field programmable gate array (FPGA)-based array processes to obtain near ASIC level speed of matching. This approach has been tested on a locally collected test data and on NIST-S, a large fingerprint database available in the public domain (Ratha et al., 1996).

Focussing has been done on the use of motion analysis to create visual representations of videos that may be useful for efficient browsing and in-

dexing in contrast with traditional frame-oriented representations. Two major approaches for motion based representations have been presented. The first approach demonstrated that dominant 2-D and 3-D motion techniques are useful in their own right for computing video mosaics through the computation of dominant scene motion and/or structure. However, this may not be adequate if object level indexing and manipulation is to be accomplished efficiently. The second approach presented addresses this issue through simultaneous estimation of an adequate number of simple 2-D motion models. A unified view of the two approaches naturally follows from the multiple model approach: the dominant motion method becomes a particular case of the multiple motion method if the number of models is fixed to be one and only the robust EM algorithm without the MDL stage employed (Sawhney, 1996).

Image content-based retrieval is emerging as an important research area with application to digital libraries and multimedia databases. The focus is being put on the image processing aspects and, in particular, using texture information for browsing and retrieval of large image data. It proposed use of Gabber wavelet features for texture analysis and provided a comprehensive experimental evaluation. Comparisons with other multi-resolution texture features using the Brodatz texture database indicate that the Gabor features provide the best pattern retrieval accuracy. An application to browsing large air photos is illustrated (Manjunath & Ma, 1996).

A method is developed for the content-based retrieval of multi-spectral satellite images using invariant representations. Since these images contain a wide variety of structures with different physical characteristics it is useful to exploit several classes of representations and algorithms. Working from a physical model for multi-band satellite image formation, existing algorithms for this application have been modified and integrated. The performance of the strategy has been demonstrated for image retrieval invariant to atmospheric and illumination auditions from a database of 166 multi-band images acquired at different times over areas of the U.S. (Healey & Jain, 1996).

The problem of retrieving images from a large database is addressed using an image as a query. The method is specifically aimed at databases that store images in JPEG format and works in the compressed domain to create index keys. A key is generated for each image in the database and is matched with the key generated for the query image. The keys are independent of the size of the image. Images that have similar keys are assumed to be similar, but there is no semantic meaning to the similarity (Shneier & Abdel-Mottaleb, 1996).

The Multi-mission VICAR Planner (MVP) is described in an article. It is an AI planning system which uses knowledge about image processing steps and their requirements to construct executable image processing scripts to support high-level science requests made to the Jet Propulsion Laboratory (JPL) Multi-mission Image Processing Subsystem (MIPS). This article describes a general AI planning approach to automation and application of the approach to a specific area of image processing for planetary science applications involving radiometric correction, color triplet reconstruction and mosaicing in which the MVP system significantly reduces the amount of effort required by image processing experts to fill a typical request (Chien & Mortensen, 1996).

Another paper presents how morphological transformations can be related to representations of a set on different lattices. (A hierarchical definition of structuring element conveys to a class of multi-grid transformations Pk that handle changes on discrete representations of regions.) The transformations correspond to upward and downward processes in a hierarchical structure, based on multi-grid transformations, a method to delineate non-perfectly-isolated objects in an nxn image requiring O(log n)time is presented. The approach considers grey level regions as sets

and processes through a pyramid to carry out geometric manipulations. Extending the concept of boundary to cope with hierarchical representations of a set, a second method, which identifies the boundaries in an image is discussed (Montiel et al., 1996).

IMEDIA project, which is related to image analysis, is the bottleneck of multimedia indexing concerns about image analysis for feature space and probabilistic modelisation, statistics and information theory for interactive browsing, similarity measure and matching. To achieve these goals, research involves the following topics: image indexing, partial queries, interactive search, multimedia indexing (Boujemma et al., 2000).

In a project named Efficient Content-Based Image Retrieval, the focus is the development of a general, scalable architecture to support fast querying of very large image databases with user-specified distance measures. They have developed algorithms and data structures for efficient image retrieval from large databases with multiple distance measures. They are investigating methods for merging their general distance-measure independent method with other useful techniques that may be distance measure specific, such as keyword retrieval and relational indexing. They are developing both new methods for combining distance measures and a framework in which users can specify their queries without detailed knowledge of the underlying metrics. They have built a prototype system to test their methods and evaluated it on both a large general image database and a smaller controlled database (Shapiro et al., 2000).

There is another work that addresses the issue of a gap existing between low-level visual features addressing the more detailed perceptual aspects and high-level semantic features underlying the more general aspects of visual data. Although plenty of research works have been devoted to this problem, so far, the gap still remains (Zhao et al., 2002).

Another chapter provides a state-of-the-art account of Visual Information Retrieval (VIR) systems and Content-Based Visual Information Retrieval (CBVIR) systems. It provides directions for future research by discussing major concepts, system design issues, research prototypes and currently available commercial solutions (Marques et al., 2002).

SUMMARY

A general introduction of the subject-area of the book has been given in this chapter. Both multimedia systems and content-based image retrieval have been discussed from the introductory level. Also, focus has been made to specify current problems in both of these fields and research efforts being made to solve them. Some of the research works done in the field of content-based image retrieval have been presented to give an idea of the research being conducted. All these should give a broad picture of the contents of issues, covered in these areas.

Chapter 1.23
Multimedia Digital Library as Intellectual Property

Hideyasu Sasaki
Keio University, Japan

Yasushi Kiyoki
Keio University, Japan

ABSTRACT

The principal concern of this chapter is to provide those in the digital library community with the fundamental knowledge on the intellectual property rights and copyrights regarding multimedia digital libraries. The main objects of our discussion are the multimedia digital libraries with content-based retrieval mechanisms. Intellectual property rights are the only means for database designers to acquire their incentive of content collection and system implementation in database assembling. We outline the legal issues on multimedia digital libraries and retrieval mechanisms. As the protection of intellectual property rights is a critical issue in the digital library community, the authors present legal schemes for protecting multimedia digital libraries and retrieval mechanisms in a systematic, engineering manner.

INTRODUCTION

Digital library is the global information infrastructure in the networked society (Borgman, 2000). The rights protection of multimedia digital libraries and retrieval mechanisms is a critical issue in the digital library community that demands intellectual property schemes for recouping their investment in database design and system implementation. In this chapter, we describe the technical and legal issues on multimedia digital libraries and retrieval mechanisms as intellectual properties.

The purpose of this chapter is to discuss copyright and intellectual property rights on digital libraries from the designer/architecture perspective, which has not been discussed with sufficient attention at the present. The end-user perspective has been discussed as an important

element for users of information services, including librarians, in the context of copyright law on multimedia digital libraries. Its typical case is the public use of copyright for educational or academic service. Content creators of digital libraries have definitely enjoyed copyright enforcement over their works under that current legal scheme. However, the designers or architectures of multimedia digital libraries do not have proper foundations for their rights protection that is to be equivalent to the copyright protection. Under this designer/architecture perspective, we especially focus on content-based retrieval and its application to multimedia digital libraries. Content-based retrieval is a promising technique for networked multimedia digital libraries whose tremendous volume demands automatic indexing rather than manual indexing for retrieval operations.

The scope of this chapter is also restricted within the current standard of laws and cases for transnational transaction and licensing of digital copyright and intellectual property rights regarding multimedia digital libraries. Cultural diversity in the Asia-Pacific region allows a number of legislative differences in copyright and intellectual property laws. Meanwhile, digital content is the object of its worldwide transaction. The harmonization of its related rights is inevitable because a number of countries have joined international trade agreements on intellectual property rights. We need a clear and uniform standard with which the Asian-Pacific countries are able to keep up with the foregoing countries.

In this chapter, we discuss three current issues on multimedia digital libraries and intellectual property laws, and then present three types of intellectual property schemes, respectively. The first issue is copyright protection of indexed digital contents that are stored in digital libraries. Its corresponding scheme is for copyrighting multimedia digital libraries that are associated with keyword-based retrieval operations. The second issue is patentability of retrieval mechanisms. Its corresponding scheme is for patenting content-based retrieval processes in multimedia digital libraries. Finally, the last issue is the limitations of copyright in the advent of content-based retrieval. Its corresponding scheme is a promising direction, which leverages the *de facto* protection of multimedia digital libraries that are associated with content-based retrieval operations.

BACKGROUND

Intellectual property law gives incentive to advance appropriate investment in database design and implementation (Jakes & Yoches, 1989). However, present legal studies are not satisfactory as the source of technical interpretation of the intellectual properties regarding multimedia digital libraries and retrieval mechanisms. With the advent of content-based image retrieval (CBIR), we face novel issues on the right protection of multimedia digital libraries and retrieval mechanisms.

Multimedia digital libraries consist of digital contents and retrieval systems. The digital contents are copyrightable materials whose stakeholders are content creators. The retrieval systems are patentable processes of database designers.

The principal problem discussed in this chapter is restricted into the conflicting interests between content creators and database designers. Intellectual property lawyers in the area of digital libraries have somehow neglected this designer/architecture perspective. The issues related to the problem are found in three stages. First, copyright does not always solve conflicting interests between content creators and database designers. Content creators create copyrightable individual contents, for example, pictures and images. Database designers integrate the entire content of each multimedia digital library with indexes or metadata. The problem is deciding which component differentiates the entire content of each digital library as an independent object of right protection from its copyrightable individual

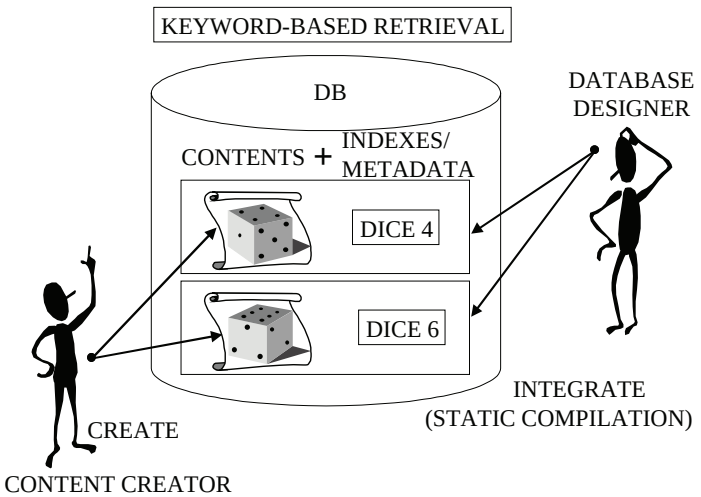
contents. Second, CBIR mechanisms need the specific examination of patentability. The computer-implemented processes in CBIR consist of the combinations of means, some of which are prior disclosed inventions. Those processes consist of the means for parameter setting that is adjusted to retrieve specific kinds of images in certain narrow domains. The problem is determining which process is of technical advancement (non-obviousness) based on its combinations of the prior arts and parameter setting. Finally, the dynamically indexed content of multimedia digital libraries goes beyond the scope of conventional copyright protection. CBIR mechanisms generate indexes to individual contents every time queries are requested for retrieval. The problem is selecting which component leverages the protection of each multimedia digital library, as the entire content is independent of its individual contents.

INDEXES AND COPYRIGHT PROTECTION

U.S. Copyright Act (1976) defines that a compilation or assembling of individual contents, that is, preexisting materials or data, is a copyrightable entity as an original work of authorship. Typical examples of copyrightable multimedia materials stored in digital libraries take a variety of forms like text or images, photos or video streams. Figure 1 outlines that the collection of static indexes and individual contents forms a component of contents-plus-indexes. That component identifies the entire content of each database, as is a static and copyrightable compilation. Indexes including metadata must be statically assigned to individual contents that are restored in databases for keyword-based retrieval operations.

Gorman & Ginsburg (1993) and Nimmer et al. (1991) state that a compilation is copyrightable as far as it is an "original work of authorship that is fixed in tangible form." A database is copyrightable in the form of a component of contents-plus-indexes while static indexes or metadata are fixed in a tangible medium of repository, database. In keyword-based retrieval, static indexes or metadata represent a certain kind of categorization of the entire content of each database. The originality on the categorization makes each database copyrightable as is different from the mere collection of its individual contents. What kind of categorization should be original to constitute a copyrightable compilation? The case

Figure 1. Digital library of visual content associated with keyword-based retrieval



of American Dental Association v. Delta Dental Plan Association (1997) determined that minimal creativity in compilation sufficed this requirement of originality on databases. A uniform scheme on the categorization regarding indexes or metadata must be formulated in an engineering manner.

COPYRIGHTING MULTIMEDIA DIGITAL LIBRARIES WITH KEYWORD-BASED RETRIEVAL

We technically interpret a scheme for copyrighting the multimedia digital libraries with keyword-based retrieval as a set of conditions that determine which type of database should be copyrightable in the form of a component of contents-plus-indexes.

Copyrightable compilation is said to be of sufficient creativity, that is, originality in the form of a component of contents-plus-indexes. Its original way of categorization is represented in the selection of the type of index or metadata that is assigned to individual contents, or the type of taxonomy regarding indexes or metadata that integrate the individual contents into the entire content of each database.

The set of conditions on the original categorization regarding indexes or metadata is formulated as shown below: A categorization regarding indexes or metadata is original only when:

1. The type of index or metadata accepts discretionary selection in the domain of a problem database; otherwise,
2. The type of taxonomy regarding indexes or metadata accepts discretionary selection in the domain of a problem database.

We describe five typical cases of original or non-original categorization regarding indexes or metadata for keyword-based retrieval. Typical cases of non-original categorization include photo film cartridge database and white pages. Those cases do not accept any discretion in the selection of the type of index or metadata, or the type of taxonomy. The photo film cartridge database uses its respective film numbers as indexes for its retrieval operations. The taxonomy of the indexes is only based on page numbering. This kind of database does not have any other discretion in its selection of the type of index or taxonomy. The white pages extract metadata from telephone numbers and names of subscribers. The case of *Feist Publications, Inc. v. Rural Telephone Service* (1991) judged that its selection of the type of taxonomy was not discretionary because its alphabetical ordering of the metadata was a single alternative in that field of practice.

Meanwhile, the discretionary selection of the type of index or metadata, or taxonomy, constitutes copyrightable compilation of minimal creativity, that is, originality on the categorization regarding indexes or metadata. Typical cases of discretionary selection of the type of index or metadata include the Web document encyclopedia and the other types of telephone directory, such as yellow pages. The latter yellow pages satisfy minimal creativity as a copyrightable compilation. The white pages list telephone numbers of subscribers in alphabetical order, while the yellow pages list business phone numbers by a variety of categories and feature-classified advertisements of various sizes. In the case of discretionary selection of the type of taxonomy, even numerical indexing, such as page numbering, could form an original compilation, when page indexes work as categorization identifiers of a specific type of taxonomy in the domain of the problem database. For example, lawyers often identify individual cases by citing their page numbers without any reference to case titles or parties. Mere page numbers work as categorization identifiers as far as the selection of page numbers is based on a specific type of taxonomy and still allows other discretionary selection of the type of index, in this case, different ranges in paging or indexing of case numbers. The component of contents-plus-indexes, in particular,

cases-plus-pages, constitutes an original work of authorship as a copyrightable compilation as affirmed by the case of *West Publishing Co. v. Mead Data Central, Inc.* (1986/1987).

Let us suppose that a database restores pictures of starfish that are manually and numerically numbered by day/hour-chronicle interval based on their significant life stages from birth to death. That database is to be an original work of authorship as a copyrightable compilation in the form of a component of contents-plus-indexes, that is, pictures-plus-numbers.

We have formulated the set of conditions that determine which type of database is copyrightable as a multimedia digital library by assessing its original categorization regarding indexes or metadata whose collection identifies the entire content of the database as the referent of copyright protection. That condition set is effective in protecting the multimedia digital libraries that are associated with keyword-based retrieval approach for image retrieval.

PATENTABILITY OF CBIR MECHANISMS

CBIR realizes its retrieval operations by performing a number of "processes," that is, methods or means for data processing that constitute computer-related inventions in the form of computer programs. The computer-related inventions often combine means for data processing, some of which are prior disclosed inventions as computer programs. Meanwhile, the processes comprise the components for parameter setting that is adjusted to retrieve specific kinds of images in certain domains, particularly in the case of domain-specific approach of CBIR.

In CBIR, parametric values determine as thresholds which candidate image is similar to an exemplary requested image by computation of similarity of visual features (Rui et al., 1999; Smeulders et al., 2000; Yoshitaka & Ichikawa, 1999). A component for parameter setting realizes the thresholding operations in the form of a computer program with a set of ranges of parametric values. The parameter-setting component is familiar in mechanic inventions. Its typical example is a patented invention of an automatic temperature controller that adjusts body temperature of raw fish in cargo within certain range as fish are not frozen but kept chilled during the course of transportation. Inventors and practitioners demand a detailed set of the conditions for patenting the data-processing processes for CBIR in multimedia digital libraries.

PATENTING CBIR MECHANISMS

In this section, we technically interpret the scheme for patenting CBIR mechanisms in the form of the conditions on patentability. We focus on combinations of prior disclosed processes and parameter setting components. The formulated conditions consist of the following three requirements for patentability: "patentable subject matter" (entrance to patent protection), "non-obviousness" (technical advancement), and "enablement" (specification) (Merges, 1997).

For satisfying the requirement for patentable subject matter, the processes for performing CBIR functions must be claimed as the means for parameter setting, which perform certain retrieval functions. Otherwise, the discussed processes are considered not as specific inventions of the data-processing processes for performing CBIR functions but as the inventions that are peripheral or just related to general retrieval functions.

A data-processing process or method is patentable subject matter in the form of a computer-related invention, that is, a computer program (U.S. Patent Act, 2003; Jakes & Yoches, 1989) as far as the "specific machine …… produce(s) a useful, concrete, and tangible result … for transforming … " physical data ("*physical transformatio*n") (in *re Alappat*, 1994). A process must "perform

independent physical acts (post-computer process activities)," otherwise, "manipulate data representing physical objects or activities to achieve a practical application (pre-computer process activities)." CBIR operations automatically generate indexes as physical results on a computer and a memory, which require pre-and post-computer process activities as indispensable procedure through data processing between feature extraction and indexing, also between indexing and classification. Inventions should be of "technological arts." That requirement does not limit patentability of computer-related inventions because technological arts are equivalent to, in broad sense, the concept of useful or practical arts (Merges, 1997).

The requirement for non-obviousness on the combinations of the processes for data processing is listed as below:

1. The processes for performing CBIR functions must comprise the combinations of prior disclosed means to perform certain functions that are not predicated from any combination of the prior arts; in addition.
2. The processes for performing CBIR functions must realize quantitative and/or qualitative advancement.

Otherwise, the discussed processes are obvious so that they are not patentable as the processes for performing CBIR functions.

First, a combination of prior disclosed means should not be "suggested" from any disclosed means "with the reasonable expectation of success" (in *re Dow Chemical Co.*, 1988). Second, its asserted function must be superior to the conventional functions that are realized in the prior disclosed or patented means. On the latter issue, several solutions for performance evaluation are proposed and applicable. Müller et al. (2001) and Manchester Visualization Center (2000) proposed benchmarking of CBIR functions. Another general strategy is restriction of the scope of problem claims into a certain narrow field to which no prior arts have been applied. This claiming strategy is local optimization of application scope.

The requirement for enablement on the parameter setting components is listed as below:

1-a. The descriptions of the processes for performing CBIR functions must specify the formulas for parameter setting, otherwise,
1-b. The disclosed invention of the processes should have its co-pending application that describes the formulas in detail. In addition,
2-a. The processes must perform a new function as domain-general approach by a combination of the prior disclosed means; otherwise,
2-b. The processes as domain-specific approach should have improved formulas for parameter setting based on the prior disclosed means for performing CBIR functions and also examples of parametric values on parameter setting in descriptions.

For 2-b, the processes must specify the means for parameter setting by "giving a specific example of preparing an" application to enable those skilled in the arts to implement their best mode of the processes without undue experiment (*Autogiro Co. of America v. United States*, 1967; *Unique Concepts, Inc. v. Brown*, 1991). U.S. Patent and Trademark Office (1996a, 1996b) suggested that the processes comprising the means, that is, the components for parameter setting must disclose at least one of the following examples of parametric values on parameter setting:

1. Working or prophetic examples of initial values or weights on parameter setting.
2. Working examples of the ranges of parametric values on parameter setting.

The "working examples" are parametric values that are confirmed to work at actual laboratory or as prototype testing results. The "prophetic examples" are given without actual work by one skilled in the art.

It is a critical problem to define the scope of equivalent modification of process patents because parametric values in parameter setting are easy to modify and adjust at application. The scope of patent enforcement extends to what is equivalent to a claimed invention, as far as it is predictable from claims and descriptions (*Graver Tank & Mfg. Co. v. Linde Air Products Co.*, 1950; *Laitran Corp. v. Rexnord, Inc.*, 1991). Especially, domain-specific approach for performing CBIR functions must distinguish its claimed invention with its examples of parametric values from other improved formulas for parameter setting that are based on prior disclosed means. The scope of the equivalent modification of a patented process is defined within a certain specified scope as suggested from the exemplary parametric values.

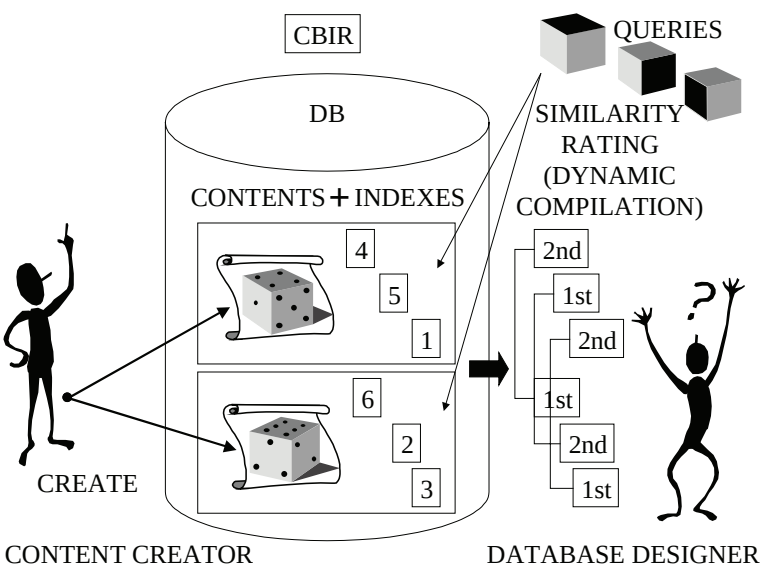
LIMITATIONS OF COPYRIGHT IN THE ADVENT OF CBIR

Two limitations on copyright are to be identified in its application to image databases as multimedia digital libraries:

1. A component of contents-plus-indexes does not identify the entire content of any database that is associated with CBIR operations; and,
2. Any copyrightable compilation in that database does not identify its entire content.

Figure 2 outlines the first limitation that the component of contents-plus-indexes, which is a collection of individual contents with *dynamic* indexes but does not identify the entire content of any database that is associated with CBIR operations. In the application of CBIR operations to a database, its component of contents-plus-indexes is just a collection of respectively rated and displayed individual contents whose similarity rating

Figure 2. A digital library of visual content associated with CBIR



order changes every time new sample images are requested as queries.

The second limitation is to be discovered in two phases. The discussed mere collection of individual contents in an image database is a static compilation without any minimal creativity in its categorization. That database is not copyrightable but so are its individual contents. Any proposed scheme does not offer the remedy for that problem at the present. The European Union legislated and executed a scheme for protecting databases, known as the *sui generis* right of database protection (Reinbothe, 1999; Samuelson, 1996). Its fundamental concept is based on the property of copyrightable compilation so that it does not protect the image databases with CBIR operations under the same reasons of the discussed limitation of the copyright protection. An only resort for a new scheme must be discovered in retrieval mechanisms that are to identify the entire content of each image database, multimedia digital library, as the referent of its protection.

PROMISING DIRECTION FOR PROTECTING MULTIMEDIA DIGITAL LIBRARIES WITH CBIR

Another new scheme must realize that the protection of multimedia digital libraries is to be leveraged by using the intellectual property of their retrieval mechanisms or data processing methodologies but not the copyright of their referents, that is, databases.

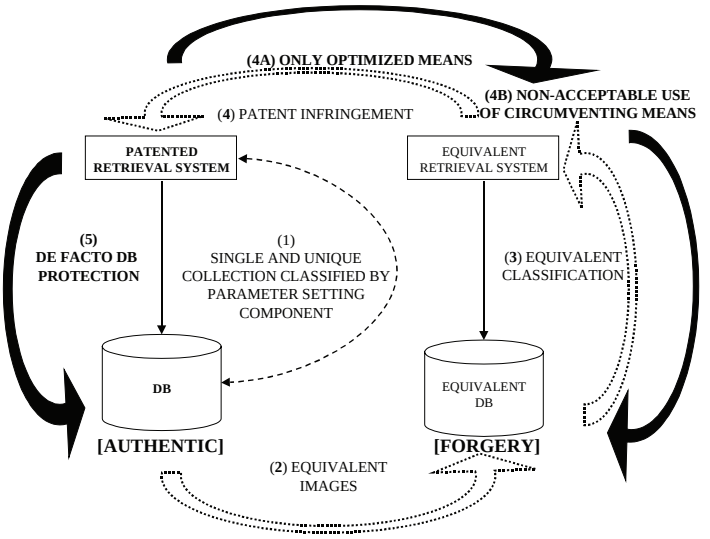
The practice in the field of bioinformatics offers a typical case of that kind of protection.

The methodologies for identifying genetic codes have been yielded with process patent in the form of computer programs, even before the admission of the patentability of genomic DNA sequences per se as material patent. A kind of exclusive protection over its referents, the gene per se, is leveraged by patenting the component of the data processing methodology that identifies a certain genetic code that is to represent the common and unique elements of genomic DNA sequences encoding a certain protein. Without such that patentable invention, any other means neither identifies the genetic code that corresponds to a specific gene nor represents the single and unique collection of genomic DNA sequences encoding a protein.

If certain conditions let a component in retrieval mechanisms identify a classification of the entire content of an image database as a single and unique collection in a specific domain, patenting that component realizes the same *de facto* protection of its referent, that is, the database with CBIR, as patenting the discussed component in bioinformatics does. It is based on a logic that CBIR is optimized in that specific domain of the image database as far as the patented component of the methodology integrates or identifies the classification of its referents (individual contents) into the single and unique collection (the entire content) (Sasaki & Kiyoki, 2003, 2002a).

That component must be discovered from consulting the technical properties of CBIR mechanisms, especially, domain-specific approach whose application focuses on the narrower or specific domains for image retrieval. In those domains, the feature extraction and index classification of the referent images are realized by optimizing the components for thresholding operations that evaluate structural similarity of extracted visual features of the images to identify a classification of the entire content of an image database. The component for thresholding operations consists of the means for selecting and/or adjusting parametric values. The parameter-setting component identifies a classification of the entire content of its referent image database by optimizing the parametric values on feature extraction and index classification in each specific domain (Sasaki & Kiyoki, 2003). That parameter setting component is to be a computer-related invention in the form of computer programs (U.S. Patent and Trademark Office, 1996a, 1996b; Sasaki &Kiyoki, 2002b, 2002c, 2005).

Figure 3. The patent-based protection scheme



A specific domain has a *sign* that is a set of visual features, for example, shape, color, texture, region, and etcetera that are extracted out of mutually similar images (Smeulders et al., 2000). Signs bridge the gaps between the sets of sample images requested as queries and the classes of mutually similar candidate images in each specific domain. When the pre-defined ranges of parametric values identify the signs and a classification of an image database as a single and unique collection, the patentable parameter-setting component leverages the de facto protection of the entire content of an image database in its referent specific domain. *Figure 3* outlines the scheme that leverages the de facto protection of an image database as a multimedia digital library in a certain specific domain:

1. Identify a specific narrow domain of an authentic image database, and assure its parameter setting component of the patented methodology to identify a classification of the entire content of an image database as a single and unique collection in a specific domain.
2. Assemble another forgery image database in the same or equivalent domain by duplicating, otherwise, restoring images that are similar or equivalent to the images of the authentic image database.
3. Discover that forgery image database to implement a circumventing methodology that classifies and identifies the same or equivalent classes of mutually similar images as the authentic patented methodology does.
4. Verify that the circumventing methodology is the equivalents to the patented methodology and infringes that methodology under the logic that without the methodology for identification no other method for retrieval is optimized in the discussed domain.
5. Realize the de facto protection of the authentic image database as is leveraged by the protection of the patented methodology for domain-specific approach of CBIR in the specific domain.

An advantage of the above patent-based protection is to use the registered right for leveraging

its de facto protection of its referent, database. Another merit is to restrict its exclusive protection leveraged by patent protection in the modest scope of specific domain. It is a well-known fact that parametric values are easy to modify and adjust in the application. Exemplary parametric values must be specified to define a clear boundary of the scope of equivalent modification of the claimed methodologies. As suggested from exemplary parametric values, the scope of modification is restricted within respective specific domains. The most significant problem in the protection of digital libraries is the preemption of application fields by the foregoing that are often the western countries. Reinbothe (1999) mentioned that any prospective protection of digital libraries should be fair to both the developers and the followers. The proposed scheme is not to have any excessive protection over a number of image databases as multimedia digital libraries in general domains.

CONCLUSION

In this chapter, we have discussed the legal issues on multimedia digital libraries and retrieval mechanisms, and technically interpreted the legal schemes for protecting multimedia digital libraries and retrieval mechanisms. The protection of its intellectual property right is a critical issue in the digital library community. We have presented the schemes for copyrighting the multimedia digital libraries with keyword-based retrieval, patenting the CBIR mechanisms, and protecting the multimedia digital libraries with CBIR.

Chapter 1.24
Data Hiding in Document Images

Edward K. Wong
Polytechnic University, USA

ABSTRACT

With the proliferation of digital media such as images, audio, and video, robust digital watermarking and data hiding techniques are needed for copyright protection, copy control, annotation, and authentication of document images. While many techniques have been proposed for digital color and grayscale images, not all of them can be directly applied to binary images in general and document images in particular. The difficulty lies in the fact that changing pixel values in a binary image could introduce irregularities that are very visually noticeable. Over the last few years, we have seen a growing but limited number of papers proposing new techniques and ideas for binary image watermarking and data hiding. In this chapter we present an overview and summary of recent developments on this important topic, and discuss important issues such as robustness and data hiding capacity of the different techniques.

INTRODUCTION

Given the increasing availability of cheap yet high quality scanners, digital cameras, digital copiers, printers and mass storage media the use of document images in practical applications is becoming more widespread. However, the same technology that allows for creation, storage and processing of documents in digital form, also provides means for mass copying and tampering of documents. Given the fact that digital documents need to be exchanged in printed format for many practical applications, any security mechanism for protecting digital documents would have to be compatible with the paper-based infrastructure. Consider for

example the problem of authentication. Clearly an authentication tag embedded in the document should survive the printing process. That means that the authentication tag should be embedded inside the document data rather than appended to the bitstream representing the document. The reason is that if the authentication tag is appended to the bitstream, a forger could easily scan the document, remove the tag, and make changes to the scanned copy and then print the modified document.

The process of embedding information into digital content without causing perceptual degradation is called *data hiding.* A special case of data hiding is *digital watermarking* where the embedded signal can depend on a secret key. One main difference between data hiding and watermarking is in whether an active adversary is present. In watermarking applications like copyright protection and authentication, there is an active adversary that would attempt to remove, invalidate or forge watermarks. In data hiding there is no such active adversary as there is no value associated with the act of removing the hidden information. Nevertheless, data hiding techniques need to be robust against accidental distortions.

A special case of data hiding is *steganography* (meaning *covered writing* in Greek), which is the science and art of secret communication. Although steganography has been studied as part of cryptography for many decades, the focus of steganography is secret communication. In fact, the modern formulation of the problem goes by the name of the *prisoner's problem*. Here Alice and Bob are trying to hatch an escape plan while in prison. The problem is that all communication between them is examined by a warden, Wendy, who will place both of them in solitary confinement at the first hint of any suspicious communication. Hence, Alice and Bob must trade seemingly inconspicuous messages that actually contain hidden messages involving the escape plan. There are two versions of the problem that are usually discussed — one where the warden is *passive*, and only observes messages, and the other where the warden is *active* and modifies messages in a limited manner to guard against hidden messages. The most important issue in steganography is that the very presence of a hidden message must be concealed. Such a requirement is not critical in general data hiding and watermarking problems.

Before we describe the different techniques that have been devised for data hiding, digital watermarking and steganography for document images, we briefly list different applications that would be enabled by such techniques.

1. *Ownership assertion.* To assert ownership of a document, Alice can generate a watermarking signal using a secret private key, and embed it into the original document. She can then make the watermarked document publicly available. Later, when Bob contends the ownership of a copy derived from Alice's original, Alice can produce the unmarked original and also demonstrate the presence of her watermark in Bob's copy. Since Alice's original is unavailable to Bob, he cannot do the same provided Alice has embedded her watermark in the proper manner (Holliman & Memon, 2000). For such a scheme to work, the watermark has to survive operations aimed at malicious removal. In addition, the watermark should be inserted in such a manner that it cannot be forged, as Alice would not want to be held accountable for a document that she does not own (Craver et al., 1998).
2. *Fingerprinting.* In applications where documents are to be electronically distributed over a network, the document owner would like to discourage unauthorized duplication and distribution by embedding a distinct watermark (or a fingerprint) in each copy of the data. If, at a later point in time, unauthorized copies of the document are

found, then the origin of the copy can be determined by retrieving the fingerprint. In this application the watermark needs to be invisible and must also be invulnerable to deliberate attempts to forge, remove or invalidate. The watermark should also be resistant to collusion. That is, a group of k users with the same document but containing different fingerprints should not be able to collude and invalidate any fingerprint or create a copy without any fingerprint.

3. *Copy prevention or control.* Watermarks can also be used for copy prevention and control. For example, every copy machine in an organization can include special software that looks for a watermark in documents that are copied. On finding a watermark the copier can refuse to create a copy of the document. In fact it is rumored that many modern currencies contain digital watermarks which when detected by a compliant copier will disallow copying of the currency. The watermark can also be used to control the number of copy generations permitted. For example a copier can insert a watermark in every copy it makes and then it would not allow further copying when presented a document that already contains a watermark.
4. *Authentication.* Given the increasing availability of cheap yet high quality scanners, digital cameras, digital copiers and printers, the authenticity of documents has become difficult to ascertain. Especially troubling is the threat that is posed to conventional and well established document based mechanisms for identity authentication, like passports, birth certificates, immigration papers, driver's license and picture IDs. It is becoming increasingly easier for individuals or groups that engage in criminal or terrorist activities to forge documents using off-the-shelf equipment and limited resources. Hence it is important to ensure that a given document was originated from a specific source and that it has not been changed, manipulated or falsified. This can be achieved by embedding a watermark in the document. Subsequently, when the document is checked, the watermark is extracted using a unique key associated with the source, and the integrity of the data is verified through the integrity of the extracted watermark. The watermark can also include information from the original document that can aid in undoing any modification and recovering the original. Clearly a watermark used for authentication purposes should not affect the quality of the document and should be resistant to forgeries. Robustness is not critical, as removal of the watermark renders the content inauthentic and hence is of no value.
5. *Metadata Binding.* Metadata information embedded in an image can serve many purposes. For example, a business can embed the Web site URL for a specific product in a picture that shows an advertisement for that product. The user holds the magazine photo in front of a low-cost CMOS camera that is integrated into a personal computer, cellular phone, or a personal digital assistant. The data are extracted from the low-quality picture and is used to take the browser to the designated Web site. For example, in the mediabridge application (*http://www.digimarc.com*), the information embedded in the document image needs to be extracted despite distortions incurred in the print and scan process. However, these distortions are just a part of a process and not caused by an active and malicious adversary.

The above list represents example applications where data hiding and digital watermarks could potentially be of use. In addition, there are many other applications in digital rights management (DRM) and protection that can benefit from data

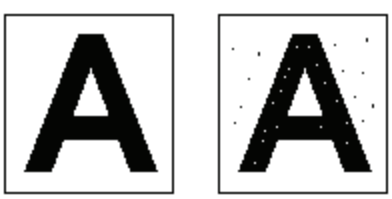
hiding and watermarking technology. Examples include tracking the use of documents, automatic billing for viewing documents, and so forth. From the variety of potential applications exemplified above it is clear that a digital watermarking technique needs to satisfy a number of requirements. Since the specific requirements vary with the application, data hiding and watermarking techniques need to be designed within the context of the entire system in which they are to be employed. Each application imposes different requirements and would require different types of watermarking schemes.

Over the last few years, a variety of digital watermarking and data hiding techniques have been proposed for such purposes. However, most of the methods developed today are for grayscale and color images (Swanson et al., 1998), where the gray level or color value of a selected group of pixels is changed by a small amount without causing visually noticeable artifacts. These techniques cannot be directly applied to binary document images where the pixels have either a 0 or a 1 value. Arbitrarily changing pixels on a binary image causes very noticeable artifacts (see Figure 1 for an example). A different class of embedding techniques must therefore be developed. These would have important applications in a wide variety of document images that are represented as binary foreground and background; for example, bank checks, financial instruments, legal documents, driver licenses, birth certificates, digital books, engineering maps, architectural drawings, road maps, and so forth. Until recently, there has been little work on watermarking and data hiding techniques for binary document images. In the remaining portion of this chapter we describe some general principles and techniques for document image watermarking and data hiding. Our aim is to give the reader a better understanding of the basic principles, inherent trade-offs, strengths, and weaknesses of document image watermarking and data hiding techniques that have been developed in recent years.

Most document images are binary in nature and consist of a foreground and a background color. The foreground could be printed characters of different fonts and sizes in text documents, handwritten letters and numbers in a bank check, or lines and symbols in engineering and architectural drawings. Some documents have multiple gray levels or colors, but the number of gray levels and colors is usually few and each local region usually has a uniform gray level or color, as opposed to the different gray levels and colors you find at individual pixels of a continuous-tone image. Some binary documents also contain grayscale images represented as half-tone images, for example the photos in a newspaper. In such images, *nxn* binary patterns are used to approximate gray level values of a gray scale image, where *n* typically ranges from two to four. The human visual system performs spatial integration of the fine binary patterns within local regions and perceives them as different intensities (Foley et al., 1990).

Many applications require that the information embedded in a document be recovered despite accidental or malicious distortions they

Figure 1. Effect of arbitrarily changing pixel values on a binary image



may undergo. Robustness to printing, scanning, photocopying, and facsimile transmission is an important consideration when hardcopy distributions of documents are involved. There are many applications where robust extraction of the embedded data is not required. Such embedding techniques are called *fragile* embedding techniques. For example, fragile embedding is used for authentication whereby any modification made to the document can be detected due to a change in the watermark itself or a change in the relationship between the content and the watermark. Fragile embedding techniques could also be used for steganography applications.

In the second section, of this chapter, we summarize recent developments in binary document image watermarking and data hiding techniques. In the third section, we present a discussion on these techniques, and in the fourth section we give our concluding remarks.

DATA HIDING TECHNIQUES FOR DOCUMENTS IMAGES

Watermarking and data hiding techniques for binary document images can be classified according to one of the following embedding methods: text line, word, or character shifting, fixed partitioning of the image into blocks, boundary modifications, modification of character features, modification of run-length patterns, and modifications of half-tone images. In the rest of this section we describe representative techniques for each of these methods.

Text Line, Word or Character Shifting

One class of robust embedding methods shifts a text line, a group of words, or a group of characters by a small amount to embed data. They are applicable to documents with formatted text.

S. Low and co-authors have published a series of papers on document watermarking based on line and word shifting (Low et al., 1995a, 1995b, 1998; Low & Maxemchuk, 1998; Maxemchuk & Low, 1997). These methods are applicable to documents that contain paragraphs of printed text. Data is embedded in text documents by shifting lines and words spacing by a small amount (1/150 inch.) For instance, a text line can be moved up to encode a '1' or down to encode a '0,' a word can be moved left to encode a '1' or right to encode '0'. The techniques are robust to printing, photocopying, and scanning. In the decoding process, distortions and noise introduced by printing, photocopying and scanning are corrected and removed as much as possible. Detection is by use of maximum-likelihood detectors. In the system they implemented, line shifts are detected by the change in the distance of the marked line and two control lines — the lines immediately above and below the marked line. In computing the distance between two lines, the estimated centroids of the horizontal profiles (projections) of the two lines are used as reference points. Vertical profiles (projections) of words are used for detecting word shifts. The block of words to be marked (shifted) is situated between two control blocks of words. Shifting is detected by computing the correlation between the received profile and the uncorrupted marked profile. The line shifting approach has low embedding capacity but the embedded data are robust to severe distortions introduced by processes such as printing, photocopying, scanning, and facsimile transmission. The word shifting approach has better data embedding capacity but reduced robustness to printing, photocopying and scanning.

In Liu et al. (1999), a combined approach that marks a text document by line or word shifting, and detects the watermark in the frequency domain by Cox et al.'s algorithm (Cox et al., 1996) was proposed. It attempts to combine the unobtrusiveness of spatial domain techniques and the good detection performance of frequency domain techniques. Marking is performed according to the line and word shifting method described above.

The frequency watermark X is then computed as the largest N values of the absolute differences in the transforms of the original document and the marked document. In the detection process, the transform of the corrupted document is first computed. The corrupted frequency watermark X^* is then computed as the largest N values of the absolute differences in the transform of the corrupted document and the original document. The detection of watermark is by computing a similarity between X and X^*. This method assumes that the transform of the original document, and the frequency watermark X computed from the original document and the marked document (before corruption) is available during the detection process.

In Brassil and O'Gorman (1996), it is shown that the height of a bounding box enclosing a group of words can be used to embed data. The height of the bounding box is increased by either shifting certain words or characters upward, or by adding pixels to end lines of characters with ascenders or descenders. The method was proposed to increase the data embedding capacity over the line and/or word shifting methods described above. Experimental results show that bounding box expansions as small as 1/300 inch can be reliably detected after several iterations of photocopying. For each mark, one or more adjacent words on an encodable text line are selected for displacement according to a selection criterion. The words immediately before and after the shifted word(s), and a block of words on the text line immediately above or below the shifted word(s), remain unchanged and are used as "reference heights" in the decoding process. The box height is measured by computing a local horizontal projection profile for the bounding box. This method is very sensitive to baseline skewing. A small rotation of the text page can cause distortions in bounding box height, even after de-skewing corrections. Proper methods to deal with skewing require further research.

In Chotikakamthorn (1999), character spacing is used as the basic mechanism to hide data. A line of text is first divided into blocks of characters. A data bit is then embedded by adjusting the widths of the spaces between the characters within a block, according to a predefined rule. This method has advantage over the word spacing method above in that it can be applied to written languages that do not have spaces with sufficiently large width for word boundaries; for example, Chinese, Japanese, and Thai. The method has embedding capacity comparable to that of the word shifting method. Embedded data are detected by matching character spacing patterns corresponding to data bits '0' or '1'. Experiments show that the method can withstand document duplications. However, improvement is needed for the method to be robust against severe document degradations. This could be done by increasing the block size for embedding data bits, but this also decreases the data embedding capacity.

Fixed Partitioning of Images

One class of embedding methods partitions an image into fixed blocks of size m x n, and computes some pixel statistics or invariants from the blocks for embedding data. They can be applied to binary document images in general; for example, documents with formatted text or engineering drawings.

In Wu et al. (2000), the input binary image is divided into 3x3 (or larger) blocks. The flipping priorities of pixels in a 3x3 block are then computed and those with the lowest scores can be changed to embed data. The flipping priority of a pixel is indicative of the estimated visual distortion that would be caused by flipping the value of a pixel from 0 to 1 or from 1 to 0. It is computed by considering the change in smoothness and connectivity in a 3x3 window centered at the pixel. Smoothness is measured by the horizontal, vertical, and diagonal transitions, and connectivity is measured by the number of black and white clusters in the

3x3 window. Data are embedded in a block by modifying the total number of black pixels to be either odd or even, representing data bits 1 and 0, respectively. Shuffling is used to equalize the uneven embedding capacity over the image. It is done by random permutation of all pixels in the image after identifying the flippable pixels.

In Koch and Zhao (1995), an input binary image is divided into blocks of 8x8 pixels. The numbers of black and white pixels in each block are then altered to embed data bits 1 and 0. A data bit 1 is embedded if the percentage of white pixels is greater than a given threshold, and a data bit 0 is embedded if the percentage of white pixels is less than another threshold. A group of contiguous or distributed blocks is modified by switching white pixels to black or vice versa until such thresholds are reached. For ordinary binary images, modifications are carried out at the boundary of black and white pixels, by reversing the bits that have the most neighbors with the opposite pixel value. For dithered images, modifications are distributed throughout the whole block by reversing bits that have the most neighbors with the same pixel value. This method has some robustness against noise if the difference between the thresholds for data bits 1 and 0 is sufficiently large, but this also decreases the quality of the marked document.

In Pan et al. (2000), a data hiding scheme using a secret key matrix K and a weight matrix W is used to protect the hidden data in a host binary image. A host image F is first divided into blocks of size mxn. For each block F_i, data bits $b_1 b_2 \ldots b_r$ are embedded by ensuring the invariant

$$SUM((F_i \oplus K) \otimes W) \equiv b_1 b_2 \ldots b_r \pmod{2^r},$$

where $\oplus$ represents the bit-wise exclusive OR operation, $\otimes$ represents pair-wise multiplication, and is the sum of all elements in a matrix. Embedded data can be easily extracted by computing:

$$SUM((F_i \oplus K) \otimes W) \pmod{2^r}$$

The scheme can hide as many as bits of data in each image block by changing at most two bits in the image block. It provides high security, as long as the block size (m x n) is reasonably large. In a 256x256 test image divided into blocks of size 4x4, 16,384 bits of information were embedded. This method does not provide any measure to ensure good visual quality in the marked document.

In Tseng and Pan (2000), an enhancement was made to the method proposed in Pan et al. (2000) by imposing the constraint that every bit that is to be modified in a block is adjacent to another bit that has the opposite value. This improves the visual quality of the marked image by making the inserted bits less visible, at the expense of sacrificing some data hiding capacity. The new scheme can hide up to bits of data in an mxn image by changing at most two bits in the image block.

Boundary Modifications

In Mei et al. (2001), the data are embedded in the eight-connected boundary of a character. A fixed set of pairs of five-pixel long boundary patterns were used for embedding data. One of the patterns in a pair requires deletion of the center foreground pixel, whereas the other requires the addition of a foreground pixel. A unique property of the proposed method is that the two patterns in each pair are dual of each other — changing the pixel value of one pattern at the center position would result in the other. This property allows easy detection of the embedded data without referring to the original document, and without using any special enforcing techniques for detecting embedded data. Experimental results showed that the method is capable of embedding about 5.69 bits of data per character (or connected component) in a full page of text digitized at 300 dpi. The method can be applied to general document images with connected components; for example, text documents or engineering drawings.

Modifications of Character Features

This class of techniques extracts local features from text characters. Alterations are then made to the character features to embed data.

In Amamo and Misaki (1999), text areas in an image are identified first by connected component analysis, and are grouped according to spatial closeness. Each group has a bounding box that is divided into four partitions. The four partitions are divided into two sets. The average width of the horizontal strokes of characters is computed as feature. To compute average stroke width, vertical black runs with lengths less than a threshold are selected and averaged. Two operations — "make fat" and "make thin" — are defined by increasing and decreasing the lengths of the selected runs, respectively. To embed a "1" bit, the "make fat" operation is applied to partitions belonging to set 1, and the "make thin" operation is applied to partitions belongs to set 2. The opposite operations are used to embed "0" bit. In the detection process, detection of text line bounding boxes, partitioning, and grouping are performed. The stroke width features are extracted from the partitions, and added up for each set. If the difference of the sum totals is larger than a positive threshold, the detection process outputs 1. If the difference is less than a negative threshold, it outputs 0. This method could survive the distortions caused by print-and-scan (re-digitization) processes. The method's robustness to photocopying needs to be furthered investigated.

In Bhattacharjya and Ancin (1999), a scheme is presented to embed secret messages in the scanned grayscale image of a document. Small sub-character-sized regions that consist of pixels that meet criteria of text-character parts are identified first, and the lightness of these regions are modulated to embed data. The method employs two scans of the document — a low resolution scan and a high resolution scan. The low-resolution scan is used to identify the various components of the document and establish a coordinate system based on the paragraphs, lines and words found in the document. A list of sites for embedding data is selected from the low resolution scanned image. Two site selection methods were presented in the paper. In the first method, a text paragraph is partitioned into grids of 3x3 pixels. Grid cells that contain predominately text-type pixels are selected. In the second method, characters with long strokes are identified. Sites are selected at locations along the stroke. The second scan is a full-resolution scan that is used to generate the document copy. The pixels from the site lists generated in the low-resolution scan are identified and modulated by the data bits to be embedded. Two or more candidate sites are required for embedding each bit. For example, if the difference between the average luminance of the pixels belonging to the current site and the next one is positive, the bit is a 1; else, the bit is a 0. For robustness, the data to be embedded are first coded using an error correcting code. The resulting bits are then scrambled and dispersed uniformly across the document page. For data retrieval, the average luminance for the pixels in each site is computed and the data are retrieved according to the embedding scheme and the input site list. This method was claimed to be robust against printing and scanning. However, this method requires that the scanned grayscale image of a document be available. The data hiding capacity of this method depends on the number of sites available on the image, and in some cases, there might not be enough sites available to embed large messages.

Modification of Run-Length

In Matsui and Tanaka (1994), a method was proposed to embed data in the run-lengths of facsimile images. A facsimile document contains 1,728 pixels in each horizontal scan line. Each run length of black (or foreground) pixels is coded using modified Huffman coding scheme according to the statistical distribution of run-lengths. In the proposed method, each run length of black pixels

is shortened or lengthened by one pixel according to a sequence of signature bits. The signature bits are embedded at the boundary of the run lengths according to some pre-defined rules.

Modifications of Half-Toned Images

Several watermarking techniques have been developed for half-tone images that can be found routinely in printed matters such as books, magazines, newspapers, printer outputs, and so forth. This class of methods can only be used for half-tone images, and are not suitable for other types of document images. The methods described in Baharav and Shaked (1999) and Wang (2001) embed data during the half-toning process. This requires the original grayscale image. The methods described in Koch and Zhao (1995) and Fu and Au (2000a, 2000b, 2001) embed data directly into the half-tone images after they have been generated. The original grayscale image is therefore not required.

In Baharav and Shaked (1999), a sequence of two different dither matrices (instead of one) was used in the half-toning process to encode the watermark information. The order in which the two matrices are applied is the binary representation of the watermark. In Knox (United States Patent) and Wang (United States Patent), two screens were used to form two halftone images and data were embedded through the correlations between the two screens.

In Fu and Au (2000a, 2000b), three methods were proposed to embedded data at pseudo-random locations in half-tone images without knowledge of the original multi-tone image and the half-toning method. The three methods, named DHST, DHPT, and DHSPT, use one half-tone pixel to store one data bit. In DHST, *N* data bits are hidden at *N* pseudo-random locations by forced toggling. That is, when the original half-tone pixel at the pseudo-random locations differs from the desired value, it is forced to toggle. This method results in undesirable clusters of white or black pixels. In the detection process, the data are simply read from the *N* pseudo-random locations. In DHPT, a pair of white and black pixels (instead of one in DHST) is chosen to toggle at the pseudo-random locations. This improves over DHST by preserving local intensity and reducing the number of undesirable clusters of white or black pixels. DHSPT improves upon DHPT by choosing pairs of white and black pixels that are maximally connected with neighboring pixels before toggling. The chosen maximally connected pixels will become least connected after toggling and the resulting clusters will be smaller, thus improving visual quality.

In Fu and Au (2001), an algorithm called *intensity selection* (IS) is proposed to select the best location, out of a set of candidate locations, for the application of the DHST, DHPT and DHSPT algorithms. By doing so, significant improvement in visual quality can be obtained in the output images without sacrificing data hiding capacity. In general, the algorithm chooses pixel locations that are either very bright or very dark. It represents a data bit as the parity of the sum of the half-tone pixels at *M* pseudo-random locations and selects the best out of the *M* possible locations. This algorithm, however, requires the original grayscale image or computation of the inverse-half-toned image.

In Wang (2001), two data hiding techniques for digital half-tone images were described: *modified ordered dithering* and *modified multiscale error diffusion*. In the first method, one of the 16 neighboring pixels used in the dithering process is replaced in an ordered or pre-programmed manner. The method was claimed to be similar to replacing the insignificant one or two bits of a grayscale image, and is capable of embedding 4,096 bits in an image of size 256 x 256 pixels. The second method is a modification of the *multi-scale error diffusion* (MSED) algorithm for half-toning as proposed in Katsavounidis and Kuo (97), which alters the binarization sequence of the error diffusion process based on the global and

local properties of intensity in the input image. The modified algorithm uses fewer floors (e.g., three or four) in the image pyramid and displays the binarization sequence in a more uniform and progressive way. After 50% of binarization is completed, the other 50% is used for encoding the hidden data. It is feasible that edge information can be retained with this method.

Kacker and Allebach propose a joint halftoning and watermarking approach (Kacker & Allebach, 2003), that combines optimization based halftoning with a spread spectrum robust watermark. The method uses a joint metric to account for the distortion between a continuous tone and a halftone (FWMSE), as well as a watermark detectability criterion (correlation). The direct binary search method (Allebach et al., 1994) is used for searching a halftone that minimizes the metric. This method is obviously extendable in that other distortion metric and/or watermarking algorithms can be used.

DISCUSSION

Robustness to printing, scanning, photocopying, and facsimile transmission is an important consideration when hardcopy distributions of documents are involved. Of the methods described above, the line and word shifting approaches described in Low et al. (1995a, 1995b, 1998), Maxemchuk and Low (1997), Low and Maxemchuk (1998), and Liu et al. (1999), and the method using intensity modulation of character parts (Bhattacharjya & Ancin, 1999) are reportedly robust to printing, scanning, and photocopying operations. These methods, however, have low data capacity. The method described in Amamo and Misaki (1999) reportedly can survive printing and scanning (re-digitization) if the strokes remain in the image. This method's robustness to photocopying still needs to be determined. The bounding box expansion method described in Brassil and O'Gorman (1996) is a robust technique, but further research is needed to develop an appropriate document deskewing technique for the method to be useful. The character spacing width sequence coding method described in Chotikakamthorn (1999) can withstand a modest amount of document duplications.

The methods described in Wu et al. (2000), Pan et al. (2000), Tseng and Pan (2000), Mei et al. (2001), Matsui and Tanaka(1994), Wang (2001), and Fu and Au (2000a, 200b, 2001) are not robust to printing, scanning and copying operations but they offer high data embedding capacity. These methods are useful in applications when documents are distributed in electronic form, when no printing, photocopying, and scanning of hardcopies are involved. The method in Koch and Zhao (1995) also has high embedding capacity. It offers some amount of robustness if the two thresholds are chosen sufficiently apart, but this also decreases image quality.

Methods based on character feature modifications require reliable extraction of the features. For example, the methods described in Amamo and Misaki (1999) and one of the two site-selection methods presented in Bhattacharjya and Anci (1999) require reliable extraction of character strokes. The boundary modification method presented in Mei et al. (2001) traces the boundary of a character (or connected-component), which can always be reliably extracted in binary images. This method also provides direct and good image quality control. The method described in Matsui and Tanaka (1994) was originally developed for facsimile images, but could be applied to regular binary document images. The resulting image quality, however, may be reduced.

A comparison of the above methods shows that there is a trade off between embedding capacity and robustness. Data embedding capacity tends to decrease with increased robustness. We also observed that for a method to be robust, data must be embedded based on computing some statistics

over a reasonably large set of pixels, preferably spread out over a large region, instead of based on the exact locations of some specific pixels. For example, in the line shifting method, data are embedded by computing centroid position from a horizontal line of text pixels, whereas in the boundary modification method, data are embedded based on specific configurations of a few boundary pixel patterns.

In addition to robustness and capacity, another important characteristic of a data hiding technique is its "security" from a steganographic point of view. That is, whether documents that contain an embedded message can be distinguished from documents that do not contain any message. Unfortunately, this aspect has not been investigated in the literature. However, for any of the above techniques to be useful in a covert communication application, the ability of a technique to be indistinguishable is quite critical. For example, a marked document created using line and word shifting can easily be spotted as it has characteristics that are not expected to be found in "normal" documents. The block-based techniques and boundary-based technique presented in the second section may produce marked documents that are distinguishable if they introduce too many irregularities or artifacts. This needs to be further investigated. A similar comment applies to the techniques presented in the second section. In general, it appears that the development of "secure" steganography techniques for binary documents has not received enough attention in the research community and much work remains to be done in this area.

Table 1 summarizes the different methods in terms of embedding techniques, robustness,

Table 1. Comparison of techniques

Techniques	**Robustness**	**Advantages (+) / Disadvantages (-)**	**Capacity**	**Limitations**
Line shifting	High		Low	Formatted text only
Word shifting	Medium		Low/Medium	Formatted text only
Bounding box expansion	Medium -	Sensitive to document skewing	Low/Medium	Formatted text only
Character spacing	Medium +	Can be applied to languages with no clear-cut word boundaries	Low/Medium	Formatted text only
Fixed partitioning -- Odd/Even pixels	None +	Can be applied to binary images in general	High	
Fixed partitioning -- Percentage of white/black pixels	Low/Medium +	Can be applied to binary images in general - Image quality may be reduced	High	
Fixed partitioning -- Logical invariant	None +	Embed multiple bits within each block + Use of a secret key	High	
Boundary modifications	None +	Can be applied to general binary images + Direct control on image quality	High	

advantages/disadvantages, data embedding capacity, and limitations. Robustness here refers to robustness to printing, photocopying, scanning, and facsimile transmission.

CONCLUSION

We have presented an overview and summary of recent developments in binary document image watermarking and data hiding research. Although there has been little work done on this topic until recent years, we are seeing a growing number of papers proposing a variety of new techniques and ideas. Research on binary document watermarking and data hiding is still not as mature as for color and grayscale images. More effort is needed to address this important topic. Future research should aim at finding methods that offer robustness to printing, scanning, and copying, yet provide good data embedding capacity. Quantitative methods should also be developed to evaluate the quality of marked images. The steganographic capability of different techniques needs to be investigated and techniques that can be used in covert communication applications need to be developed.

Chapter 1.25
Emergent Semantics: An Overview

ABSTRACT

The semantic gap is recognized as one of the major problems in managing multimedia semantics. It is the gap between sensory data and semantic models. Often the sensory data and associated context compose situations which have not been anticipated by system architects. Emergence is a phenomenon that can be employed to deal with such unanticipated situations. In the past, researchers and practitioners paid little attention to applying the concepts of emergence to multimedia information retrieval. Recently, there have been attempts to use emergent semantics as a way of dealing with the semantic gap. This chapter aims to provide an overview of the field as it applies to multimedia. We begin with the concepts behind emergence, cover the requirements of emergent systems, and survey the existing body of research.

INTRODUCTION

Managing media semantics should not necessarily involve semantic descriptions or classifications of media objects for future use. Information needs, for a user, can be task dependent, with the task itself evolving and not known beforehand. In such situations, the semantics and structure will also evolve, as the user interacts with the content, based on an abstract notion of the information required for the task. That is, users can interpret multimedia content, in context, at the time of information need. One way to achieve this is through a field of study known as *emergent semantics.*

Emergence is the phenomenon of complex structures arising from interactions between simple units. Properties or features appear that were not previously observed as functional characteristics of the units. Though constraints on a system can influence the formation of the emergent structure, they do not directly describe it. While emergence is a new concept in multimedia, it has been used in fields such as biology, physics and economics, as well as having a rich philosophical history. To the best of our knowledge, commercial emergent systems do not currently exist. However, there is research into the various technologies that would be required. This chapter aims to outline some characteristics of emergent systems and relevant tools and techniques.

The foundation for computational emergence is found in the constrained generating procedures (CGP) of John Holland (Holland, 2000). Initially there are only simple units and mechanisms. These mechanisms interact to form complex mechanisms, which in turn interact to form very complex mechanisms. This interaction results in self-organization through synthesis. If we relate the concept of CGP to multimedia, the simple units are sensory data, extracted features or even multimedia objects. Participating units can also come from other sources such as knowledge bases. Semantic emergence occurs when meaningful behaviour (phenotype) or complex semantic representation (genotype) arises from the interaction of these units. This includes user interaction, the influence of context, and relationships between media.

Context helps to deal with the problem of subjectivity, which occurs when there are multiple interpretations of a multimedia instance. World knowledge and context help to select one interpretation from the many. Ideally, we want to form semantic structures that can be understood by third parties who do not have access to the multimedia instance. This is not the same as relevance to the user. A system might want to determine what is of interest to one user, and have that understood by another.

We note that a multimedia scene is not reality; it is merely a reference to a referent in reality. Similarly, the output from emergence is a reference, hopefully useful to the user of the information. We use the linguistic terms "reference" and "referent" to indicate existence in the "modeled world" and the "real world," respectively. There is a danger in confusing the two (Minsky, 1988). The referenced meaning is embedded in our experience. This is similar to attribute binding using Dublin Core metadata (Hillmann, 2003), where the standard attribute name is associated with the commonly understood semantic.

The principal benefit of emergence is dealing with unanticipated situations. Units in unanticipated configurations or situations will still interact with each other in simple ways. Emergent systems, ideally, take care of themselves, without needing intervention or anticipation on the part of the system architect (Staab 2002). However, the main advantage of emergent semantics is also its greatest flaw. As well as dealing with unanticipated situations, it can also produce unanticipated results. We cannot control the outcomes. They might be useful, trivial or useless, or — in the worst case — misleading. However, we can constrain the scope of output by constraining the inputs and the ground truths. We can also ask for multiple interpretations. Sometimes, a structure is better understood if one can appreciate the other forms it can take.

In the next section, we state the requirements of emergent semantics. This will be followed by a description of existing research. In the last section, we identify gaps in the research, and suggest future directions.

EMERGENT SYSTEMS

Both complete order (regularity) and complete chaos (randomness) are very simple. Complexity occurs between the two, at a place known as "the edge of chaos" (Langton, 1990). Emergence results in complex systems, forming spontane-

ously from the interactions of many simple units. In nature, emergence is typically expressed in self-assembly, such as (micro-level) crystal formation and (macro-level) weather systems. These systems form naturally without centralized control. Similarly, emergence is useful in computer systems, when centralized control is impractical. The resources needed in these systems are primarily simple building blocks capable of interacting with each other and their environment (Holland, 2000). However, we are not interested in all possible complex systems that may form. We are interested in systems that might form useful semantic structures. We need to set up environments where the emergence is likely to result in complex semantic representation or expression (Whitesides & Grzybowski, 2003; Crutchfield, 1993; Potgeiter & Bishop, 2002). It is therefore necessary to understand the characteristics and issues involved in emergent information systems.

We lead our discussion through the example of an ant colony. An ant colony is comprised, primarily, of many small units known as ants. Each ant can only do simple tasks; for example, walk, carry, lay a pheromone trail, follow a trail, and so forth. However, the colony is sophisticated enough to thoroughly explore and manage its environment. Several characteristics of emergent systems are demonstrated in the ant colony metaphor: interaction, synthesis and self-organization. The main emergent phenomenon is self-organization, expressed in specialized ants being where the colony needs them, when appropriate. These ants and others, the ant interactions, the synthesis and self-organization, compose the ant colony. See Bonabeau and Theraulaz (2000) for more details.

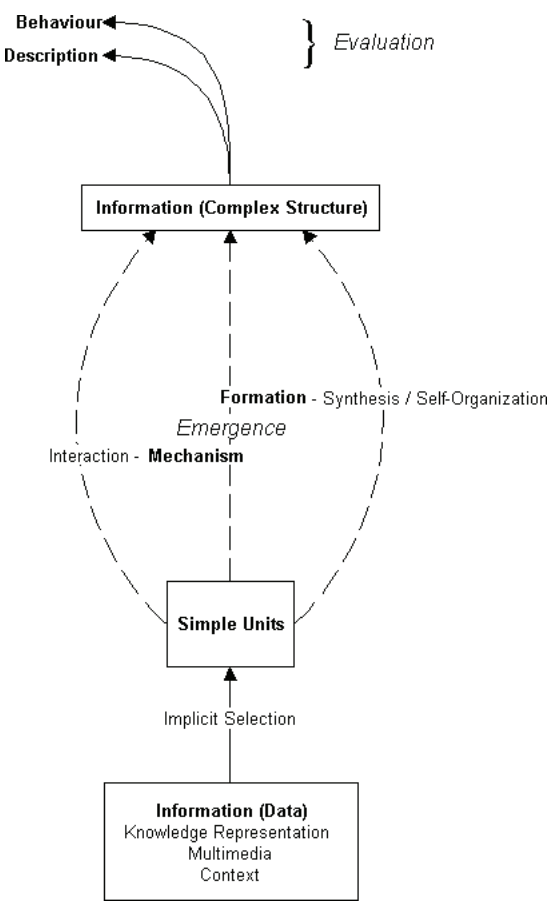
This section describes the characteristics and practical issues of emergent systems. They constitute our requirements. These include, but are not limited to, interaction, synthesis, self-organization, knowledge representation, context and evaluation.

Characteristics of Emergent Systems

The requirements of emergent semantic systems (Figure 1) can be seen from three main perspectives: information, mechanism and formation. Information is what we ultimately want (the result of the emergence). It can also be what we need (a source of units for interaction). Some of this information is implicit in the multimedia and context. Other information is either implicit or explicit in stored knowledge.

It might seem that nothing particularly useful happens at the scope of two units interacting. However, widening our field of view to take in the interaction of many units, we should see synthesis

Figure 1. Emergent semantic systems



of complex semantic units, and eventually self-organization of the unit population into semantic structures. These semantic structures can then be used to address the information need and augment the knowledge used by initial interaction.

Context influences the emergent structures. We need mechanisms which enable different interactions to occur depending on the context. These mechanisms also need to implicitly select, from the data, the salient units for each situation; either that or cause the interaction of those units, to have a greater effect.

Information

If humans are to evaluate the emergence, they must either observe system behaviour (phenotype) or a knowledge representation (genotype). The system representation must be translatable to terms a human can understand, or to an intermediate representation that can provide interaction. Typically, for this to be possible, the domain needs to be well known. Unanticipated events might not be translated well. Though we deal with the unanticipated, we must communicate in terms of the familiar. Emergence must be in terms of the system being interpreted. Otherwise we run the risk of infinite regression (Crutchfield, 1993). The environment, context and user should be included as part of the system. We need semantic structures, which contain the result of emergence, to be part of the system.

Context will either determine which of the many interpretations are appropriate or constrain the interpretation formation. Context is taken mainly from the user or from the application domain. Spatial and temporal positioning of features can also provide context, depending on the domain. The significance of specialized information, such as geographical position or time point, would be part of application domains such as fire fighting or astronomy. It is known in film theory as the Kuleshov effect. Reordering shots in a scene affects interpretation (Davis, Dorai, & Nack, 2003). Context supplies the system with constraints on relationships between entities. It can also affect the granularity and form of semantic output: classification, labelled multimedia objects, metadata, semantic networks, natural language description, or system behaviour. Different people will want to know different things.

Mechanism

The defining characteristic of useful emergent systems is that simple units can interact to provide complex and useful structures. Interaction[1] is the notion that units[2] in the system will interact to form a combined entity, which has properties that no unit has separately. The interaction is significant. Examining the units in isolation will not completely explain the properties of the whole. For two or more units to interact some mechanism must exist which enables them to interact. The mere presence of two salient units doesn't mean that they are able to interact.

Before we can reap the benefits of units interacting, we need units. These units might be implied by the data. Explicit selection of units by a central controller would not be part of an emergent process. Emergence involves implicit selection of the right units to interact. The environment should make it likely for salient units to interact. Possibly all units interact, with the salient units interacting more. In different contexts, different units will be the salient units. The context should change which units are more likely to interact, or the significance of their interaction.

Formation

"Bridge laws, linking micro and macro properties, are emergent laws if they are not semantically implied by initial micro conditions and micro laws" (McLaughlin, 2001).

Synthesis involves a group of units composing a recognisable whole. Most systems do analysis

— which involves top-down reduction and a control structure performing analysis. Synthesis is essentially the interaction mechanism seen at another level or from a different perspective. A benefit of emergence is that the system designer is freed from having to anticipate everything. Synthesis involves bottom-up emergence, which results in a complex structure. The unanticipated interaction of simple units might carry out an unanticipated and complex task. We lessen the need for a high-level control structure that tries to anticipate all possible future scenarios. Boids (Reynolds, 1987) synthesizes flocking behaviour in a population of simple units. Each unit in the flock follows simple laws, knowing only how to interact with its closest neighbours. The knowledge of forming a flock isn't stored in any unit in the flock. Unanticipated obstacles are avoided by the whole flock, which reforms if split up.

Self-Organization involves a population of units which appear to determine their own collective form and processes. "Self-assembly is the autonomous organization of components into patterns or structures without human intervention" (Whitaker, 2003; Whitesides & Grzybowski, 2003). Similar though less complex, self-organization occurs in *artificial life* (Waldrop, 1992). It attempts to mimic biological systems by capturing an abstract model of evolution. Organisms have genes, which specify simple attributes or behaviours. Populations of organisms interact to produce complex systems.

ISSUES

Evaluation

The 'Semantic Gap' is industry jargon for the gap between sensory information and the complex model in a human's mind. The same sensory information provides some of the units which participate in computational emergence. The semantic structures, which are formed, are the system's complex model. Since emergence is not something controlled, we cannot make sure that the system's complex model will be the same as the human's complex model. The ant colony is not controlled, though we consider it successful. If the ant colony self-organized in a different way, we might consider that structure successful as well. There may be many acceptable, emergent semantic structures. We need to know whether the semantic emergence is appropriate, to either the user or task. Therefore, we need to evaluate the emergence, either through direct communication of the semantic structure or though system behaviour.

Scalability

This notion of scale is slightly different to traditional notions. We can scale with respect to domain and richness of data. Most approaches for semantics constrain the domain of knowledge, such that the constraints themselves provide ground truths. If a system tries to cater for more domains, it loses some of the ground truths. Richness of data refers to numbers of units and types of units available. If the amount of data is too small, we might not have enough interaction to create a meaningful structure. A higher amount of data increases the number of units and types available. Unit pairings increase exponentially with increasing units. A system where all units try to interact with all other units might stress the process power of the system. A system without all possible interactions might miss the salient interactions. It is also uncertain whether increasing data richness will lead to finer granularity of semantic structure or lesser ability to settle on a stable structure.

Augmentation

Especially for iterative processes, it might be useful to incrementally add knowledge back to the system. The danger here is that in order to reapply what has been "learned" the system will

have to recognise situations which have occurred before with different sensory characteristics; for example, two pictures of the same situation taken from different angles.

CURRENT RESEARCH

Having described the requirements in abstract, we will now describe the tools and techniques which address the requirements.

Information

Knowledge representation, for emergence, includes ontology, metadata and genetic algorithm strings. The use of templates and grammars, which can communicate semantics in terms of the media, aren't emergent techniques as their semantic structure is predefined and the multimedia content anticipated.

Metadata (data about data) can be used as an alternative semantic description of multimedia content. MPEG-7 has a description stream, which is associated with the multimedia stream by using temporal operators. The description resides with the data. However, it is difficult in advance to provide metadata for every possible future interpretation of an event. The metadata can instead be derived from emergent semantic structures. If descriptions are needed, natural language can be derived from predicates associated with modeled concepts (Kojima, Tamura, & Fukunaga, 2002).

Classically, ontology is the study of being. The computer industry uses the term to refer to fact bases, repositories of properties and relations between objects, and semantic networks (such as Princeton's WordNet). Some ontology is used for reference, with multimedia objects or direct sensory inputs being used to index the ontology (Hoogs, 2001; Kuipers, 2000). Other ontology attempts to capture how humans communicate their own cognitive structures. The Semantic Web attempts to use ontology to access the semantics implicit in human communication (Maedche, 2002). Semantic networks consist of a skeleton of low-level data which can be augmented by adding semantic annotation nodes (Nack, 2002). The low-level data consists of the multimedia or ground truths, which can act as units in an emergent system. The annotation nodes can contain the results of emergence, and they are not permanent. This has the advantage of providing metadata-like properties, which can also be changed for different contexts.

In genetic algorithms, knowledge representation (genotype) lies in evolving strings. The strings can contain units and the operators that act on them (Gero & Ding, 1997). The genotypes evolve over several generations, with the successful[3] genes selected to generate the next generation. Knowledge and context are acquired across generations.

Context is taken from the domain, the data instances, or the user. A user's context is mainly taken from their interaction history. Their personal history and current mental state are harder to measure. The user's role during context gathering can be active (direct manipulation) or passive (observation).

Direct Manipulation

The user can actively communicate context to the system. Santini, Gupta, and Jain (2001) ask their users to organize images in a database. They use the example of a portrait. If the portrait is in a cluster of paintings, then the semantic is "painting." If it is in a cluster of people, the semantic is "people" or "faces". The same image can be a reference to different referents, which can be intangible ideas as well as tangible objects. CollageMachine (Kerne, 2002) is a Web browsing tool which tries to predict user browsing intentions. The system tries to predict possible lines of user inquiry and selects multimedia components of those to display. Reorganization of those com-

ponents, by the user, is used by the system to adjust its model.

Observation

The context of a multimedia instance is taken from past and future subjects of user attention. The entire path taken, or group formed, by a user provides an interpretation for an individual node. The whole provides the context for the part. Emergence depends on what the user thinks the data are, though the user does not need to know how they draw conclusions from observing the data. The emergence of semantics can be made by observing human and machine agent interaction (Staab, 2002). Context, at each point in the user's path, is supplied by their navigation (Grosky, Sreenath, & Fotouhi, 2002). The user's interpretation can be different from the authors' intentions. The Web is considered a directed graph (nodes: Web pages, edges: links). Adjacent nodes are considered likely to have similar semantics, though attempts are made to detect points of interest change. The meaning of a Web page (and multimedia instances in general) emerges through use and observation.

Grouping

In order to model what humans can observe, it is often helpful to model human vision. In computer vision, grouping algorithms (based on human vision) are used to form higher-level structures from units within an image (Engbers & Smeulders, 2003). An algorithm can be an emergent technique if it can adapt dynamically to context.

Context can come from sources other than users. Multiple media can be associated with data events to help in disambiguating semantics (Nakamura & Kanade, 1997). Context in genetic algorithms is sensed over many generations, if one interprets that better performance in the environment is response to context. The domain, in schemata agreement, is partly defined by the parties involved.

Mechanism

Mechanisms of automatic, implicit unit selection and interaction are yet to be developed for semantic emergence. This is a gap in the literature that will need to be filled. Current mechanisms involve the user as a unit. The semantics emerge through interaction of the user's own context with multimedia components (Santini & Jain, 1999; Kerne, 2002). The user decides which things interact, either actively or passively. In genetic algorithms, fitness functions decide how gene strings evolve (Gero & Ding, 1997). Genetic algorithms can be used to lessen the implicit selection problem by reducing the search spaces of how units interact, which units interact, and which things are considered units.

A similar situation arises with evaluation of emerged semantics. The current thinking is that humans are needed to evaluate accuracy or reasonableness. In genetic algorithms, the representation (genotype) can be evaluated indirectly by testing the phenotype (expression).

Simply having all the necessary sensory (and other) information present will not necessarily result in interaction occurring. Information from ontology could be used in decision making, or in suggesting other units for interaction. Explicitly identifying units for interaction might be a practical nonemergent step. Units can be feature patterns rather than individual features (Fan, Gao, Luo, & Hacid, 2003). Templates can be used to search for units suggested by the ontology. Well-known video structures can be used to locate salient units within video sequences (Russell, 2000; Dorai & Venkatesh, 2001; Venkatesh & Dorai, 2001). Data can provide context by affecting the perception or emotions of the observer. Emotions can be referents. Low-level units, such as tempo and colour, in the multimedia instance, act as symbols which reference them.

Formation

In genetic algorithms, synthesis occurs between generations. The genotype is self-organizing. With direct manipulation and user observation, synthesis and organization come in the form of users putting things together.

In schemata agreement, region synthesis leads to self-organization. It is designed to be adaptable to unfamiliar schemata. Agreement can be used to capture relationships later. Emergence occurs as pairs of nodes in decentralised P2P (peer-to-peer) systems attempt to form global semantic agreements by mapping their respective schemata (Aberer, Cudre-Mauroux, & Hauswirth, 2003). Regions of similar property emerge as nodes in the network are connected pair wise, and as other nodes link to them (Langley, 2001). Unfortunately, this work does not deal with multimedia. There has been recent interest in combining the areas of multimedia, data mining and knowledge discovery. However, the semantics here are not emergent. There is also data mining research into multimedia using Self-Organizing Maps (SOM), but this is not concerned with semantics (Petrushin, Kao, & Khan, 2003; Simoff & Zaiane, 2000).

CONCLUSION

A major difficulty in researching the concept of emergent semantics in multimedia is that there are no complete systems integrating the various techniques. While there is work in knowledge representation, with respect to both semantics and multimedia, to the best of our knowledge, there's very little in interaction, synthesis and self-organization. There is the work on schemata agreement (nonmultimedia) and some work on Self-Organizing Maps (nonsemantic), but nothing combining them. The little that has been done involves users to provide context and genetic algorithms to reduce problem spaces.

One of the gaps to be filled is developing interaction mechanisms, which enable possibly unanticipated data to interact with each other and their environment. Even if we can trust the process, we are still dependent on its inputs — the simple units that interact. The set of units needs to be sufficiently rich to enable acceptable emergence. Ideally, salient features (even patterns) should naturally select themselves during emergence, though this may require participation of all units, placing a high computational load on the system. Part of the problem, for emergence techniques, is that the simple interactions must occur in parallel, and in numbers great enough to realise self-organization. The future will probably have more miniaturized systems, capable of true parallelism in quantum computers. A cubic millimetre of the brain holds the equivalent of 4 km of axonal wiring (Koch, 2001). Perhaps greater parallelism will permit interaction of all available units.

There is motivation for research into nonverbal computing, where the users are illiterate (Jain, 2003). Without user ability to issue and access abstract concepts, the concepts must be inferred. Experiential computing (Jain, 2003; Sridharan, Sundaram, & Rikasis, 2003) allows users to interact with the system environment, without having to build a mental model of the environment. They seek a symbiosis formed from human and machine, taking advantage of their respective strengths. These systems are insight facilitators. They help us make sense of our own context by engaging our senses directly, as opposed to being confronted by an abstract description. Experiential computing, while in its infancy now, might in the future enable implicit relevance feedback. The user's interactions with the system could cause both emergence and verification of semantics.

Section 2

Development and Design Methodologies

This section provides in-depth coverage of conceptual architectures, frameworks and methodologies related to the design and implementation of multimedia technologies. Throughout these contributions, research fundamentals in the discipline are presented and discussed. From broad examinations to specific discussions on electronic tools, the research found within this section spans the discipline while also offering detailed, specific discussions. Basic designs, as well as abstract developments, are explained within these chapters, and frameworks for designing successful multimedia interfaces, applications, and even environments are discussed.

Chapter 2.1
Content-Based Multimedia Retrieval

Chia-Hung Wei
University of Warwick, UK

Chang-Tsun Li
University of Warwick, UK

INTRODUCTION

In the past decade, there has been rapid growth in the use of digital media such as images, video, and audio. As the use of digital media increases, effective retrieval and management techniques become more important. Such techniques are required to facilitate the effective searching and browsing of large multimedia databases.

Before the emergence of content-based retrieval, media was annotated with text, allowing the media to be accessed by text-based searching (Feng et al., 2003). Through textual description, media can be managed, based on the classification of subject or semantics. This hierarchical structure allows users to easily navigate and browse, and can search using standard Boolean queries. However, with the emergence of massive multimedia databases, the traditional text-based search suffers from the following limitations (Djeraba, 2003; Shah et al., 2004):

- Manual annotations require too much time and are expensive to implement. As the number of media in a databases grows, the difficulty finding desired information increases. It becomes infeasible to manually annotate all attributes of the media content. Annotating a 60-minute video containing more than 100,000 images consumes a vast amount of time and expense.

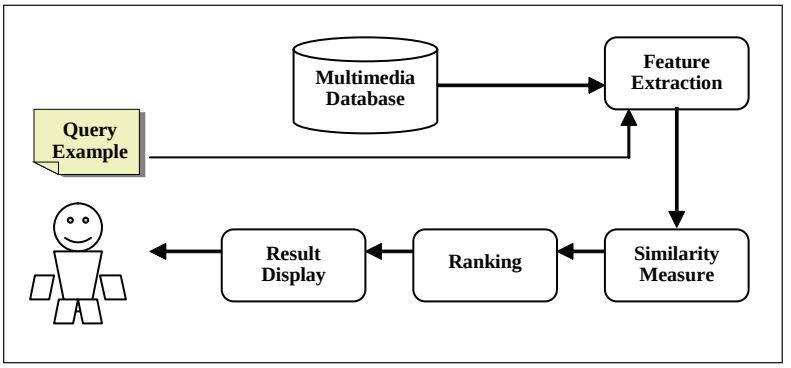
- Manual annotations fail to deal with the discrepancy of subjective perception. The phrase "a picture is worth a thousand words" implies that the textual description is not sufficient for depicting subjective perception. Capturing all concepts, thoughts, and feelings for the content of any media is almost impossible.
- Some media contents are difficult to describe concretely in words. For example, a piece of melody without lyrics or an irregular organic shape cannot be expressed easily in textual form, but people expect to search media with similar contents based on examples they provide. In an attempt to overcome these difficulties, content-based retrieval employs content information to automatically index data with minimal human intervention.

APPLICATIONS

Content-based retrieval has been proposed by different communities for various applications. These include:

- **Medical Diagnosis:** The amount of digital medical images used in hospitals has increased tremendously. As images with the similar pathology-bearing regions can be found and interpreted, those images can be applied to aid diagnosis for image-based reasoning. For example, Wei & Li (2004) proposed a general framework for content-based medical image retrieval and constructed a retrieval system for locating digital mammograms with similar pathological parts.
- **Intellectual Property:** Trademark image registration has applied content-based retrieval techniques to compare a new candidate mark with existing marks to ensure that there is no repetition. Copyright protection also can benefit from content-based retrieval, as copyright owners are able to search and identify unauthorized copies of images on the Internet. For example, Wang & Chen (2002) developed a content-based system using hit statistics to retrieve trademarks.
- **Broadcasting Archives:** Every day, broadcasting companies produce a lot of audiovisual data. To deal with these large archives, which can contain millions of hours of video and audio data, content-based retrieval techniques are used to annotate their contents and summarize the audiovisual data to drastically reduce the volume of raw footage. For example, Yang et al. (2003) developed a content-based video retrieval system to support personalized news retrieval.

Figure 1. A conceptual architecture for content-based retrieval



- **Information Searching on the Internet:** A large amount of media has been made available for retrieval on the Internet. Existing search engines mainly perform text-based retrieval. To access the various media on the Internet, content-based search engines can assist users in searching the information with the most similar contents based on queries. For example, Hong & Nah (2004) designed an XML scheme to enable content-based image retrieval on the Internet.

DESIGN OF CONTENT-BASED RETRIEVAL SYSTEMS

Before discussing design issues, a conceptual architecture for content-based retrieval is introduced and illustrated in Figure 1.

Content-based retrieval uses the contents of multimedia to represent and index the data (Wei & Li, 2004). In typical content-based retrieval systems, the contents of the media in the database are extracted and described by multi-dimensional feature vectors, also called descriptors. The feature vectors of the media constitute a feature dataset. To retrieve desired data, users submit query examples to the retrieval system. The system then represents these examples with feature vectors. The distances (i.e., similarities) between the feature vectors of the query example and those of the media in the feature dataset are then computed and ranked. Retrieval is conducted by applying an indexing scheme to provide an efficient way to search the media database. Finally, the system ranks the search results and then returns the top search results that are the most similar to the query examples.

For the design of content-based retrieval systems, a designer needs to consider four aspects: feature extraction and representation, dimension reduction of feature, indexing, and query specifications, which will be introduced in the following sections.

FEATURE EXTRACTION AND REPRESENTATION

Representation of media needs to consider which features are most useful for representing the contents of media and which approaches can effectively code the attributes of the media. The features are typically extracted off-line so that efficient computation is not a significant issue, but large collections still need a longer time to compute the features. Features of media content can be classified into low-level and high-level features.

Low-Level Features

Low-level features such as object motion, color, shape, texture, loudness, power spectrum, bandwidth, and pitch are extracted directly from media in the database (Djeraba, 2002). Features at this level are objectively derived from the media rather than referring to any external semantics. Features extracted at this level can answer queries such as "finding images with more than 20% distribution in blue and green color," which might retrieve several images with blue sky and green grass (see Picture 1). Many effective approaches to low-level feature extraction have been developed for various purposes (Feng et al., 2003; Guan et al., 2001).

High-Level Features

High-level features are also called semantic features. Features such as timbre, rhythm, instruments, and events involve different degrees of semantics contained in the media. High-level features are supposed to deal with semantic queries (e.g.,"finding a picture of water" or "searching for Mona Lisa Smile"). The latter query contains higher-degree semantics than the former. As water in images displays the homogeneous texture represented in low-level features, such a query is easier to process. To retrieve the latter query, the

retrieval system requires prior knowledge that can identify that Mona Lisa is a woman, who is a specific character rather than any other woman in a painting.

The difficulty in processing high-level queries arises from external knowledge with the description of low-level features, known as the semantic gap. The retrieval process requires a translation mechanism that can convert the query of "Mona Lisa Smile" into low-level features. Two possible solutions have been proposed to minimize the semantic gap (Marques & Furht, 2002). The first is automatic metadata generation to the media. Automatic annotation still involves the semantic concept and requires different schemes for various media (Jeon et al., 2003). The second uses relevance feedback to allow the retrieval system to learn and understand the semantic context of a query operation. Relevance feedback will be discussed in the Relevance Feedback section.

Picture 1. There are more than 20% distributions in blue and green color in this picture

DIMENSION REDUCTION OF FEATURE VECTOR

Many multimedia databases contain large numbers of features that are used to analyze and query the database. Such a feature-vector set is considered as high dimensionality. For example, Tieu & Viola (2004) used over 10,000 features of images, each describing a local pattern. High dimensionality causes the "curse of dimension" problem, where the complexity and computational cost of the query increases exponentially with the number of dimensions (Egecioglu et al., 2004). Dimension reduction is a popular technique to overcome this problem and support efficient retrieval in large-scale databases. However, there is a tradeoff between the efficiency obtained through dimension reduction and the completeness obtained through the information extracted. If each data is represented by a smaller number of dimensions, the speed of retrieval is increased. However, some information may be lost. One of the most widely used techniques in multimedia retrieval is Principal Component Analysis (PCA). PCA is used to transform the original data of high dimensionality into a new coordinate system with low dimensionality by finding data with high discriminating power. The new coordinate system removes the redundant data and the new set of data may better represent the essential information. Shyu et al. (2003) presented an image database retrieval framework and applied PCA to reduce the image feature vectors.

INDEXING

The retrieval system typically contains two mechanisms: similarity measurement and multidimensional indexing. Similarity measurement is used to find the most similar objects. Multidimensional indexing is used to accelerate the query performance in the search process.

Similarity Measurement

To measure the similarity, the general approach is to represent the data features as multi-dimensional points and then to calculate the distances between the corresponding multi-dimensional points (Feng et al., 2003). Selection of metrics has a direct impact on the performance of a retrieval system. Euclidean distance is the most common metric used to measure the distance between two points in multi-dimensional space (Qian et al., 2004). However, for some applications, Euclidean distance is not compatible with the human perceived similarity. A number of metrics (e.g., Mahalanobis Distance, Minkowski-Form Distance, Earth Mover's Distance, and Proportional Transportation Distance) have been proposed for specific purposes. Typke et al. (2003) investigated several similarity metrics and found that Proportional Transportation Distance fairly reflected melodic similarity.

Multi-Dimensional Indexing

Retrieval of the media is usually based not only on the value of certain attributes, but also on the location of a feature vector in the feature space (Fonseca & Jorge, 2003). In addition, a retrieval query on a database of multimedia with multi-dimensional feature vectors usually requires fast execution of search operations. To support such search operations, an appropriate multi-dimensional access method has to be used for indexing the reduced but still high dimensional feature vectors. Popular multi-dimensional indexing methods include R-tree (Guttman, 1984) and R*-tree (Beckmann et al., 1990). These multi-dimensional indexing methods perform well with a limit of up to 20 dimensions. Lo & Chen (2002) proposed an approach to transform music into numeric forms and developed an index structure based on R-tree for effective retrieval.

QUERY SPECIFICATIONS

Querying is used to search for a set of results with similar content to the specified examples. Based on the type of media, queries in content-based retrieval systems can be designed for several modes (e.g., query by sketch, query by painting [for video and image], query by singing [for audio], and query by example). In the querying process, users may be required to interact with the system in order to provide relevance feedback, a technique that allows users to grade the search results in terms of their relevance. This section will describe the typical query by example mode and discuss the relevance feedback.

Query by Example

Queries in multimedia retrieval systems are traditionally performed by using an example or series of examples. The task of the system is to determine which candidates are the most similar to the given example. This design is generally termed Query By Example (QBE) mode. The interaction starts with an initial selection of candidates. The initial selection can be randomly selected candidates or meaningful representatives selected according to specific rules. Subsequently, the user can select one of the candidates as an example, and the system will return those results that are most similar to the example. However, the success of the query in this approach heavily depends on the initial set of candidates. A problem exists in how to formulate the initial panel of candidates that contains at least one relevant candidate. This limitation has been defined as page zero problem (La Cascia et al., 1998). To overcome this problem, various solutions have been proposed for specific applications. For example, Sivic and Zisserman (2004) proposed a method that measures the reoccurrence of spatial configurations of viewpoint invariant features to obtain the principal objects, characters, and scenes, which can be used as entry points for visual search.

Relevance Feedback

Relevance feedback was originally developed for improving the effectiveness of information retrieval systems. The main idea of relevance feedback is for the system to understand the user's information needs. For a given query, the retrieval system returns initial results based on predefined similarity metrics. Then, the user is required to identify the positive examples by labeling those that are relevant to the query. The system subsequently analyzes the user's feedback using a learning algorithm and returns refined results. Two of the learning algorithms frequently used to iteratively update the weight estimation were developed by Rocchio (1971) and Rui and Huang (2002).

Although relevance feedback can contribute retrieval information to the system, two challenges still exist: (1) the number of labeled elements obtained through relevance feedback is small when compared to the number of unlabeled in the database; (2) relevance feedback iteratively updates the weight of high-level semantics but does not automatically modify the weight for the low-level features. To solve these problems, Tian et al. (2000) proposed an approach for combining unlabeled data in supervised learning to achieve better classification.

FUTURE RESEARCH ISSUES AND TRENDS

Since the 1990s, remarkable progress has been made in theoretical research and system development. However, there are still many challenging research problems. This section identifies and addresses some issues in the future research agenda.

Automatic Metadata Generation

Metadata (data about data) is the data associated with an information object for the purposes of description, administration, technical functionality, and so on. Metadata standards have been proposed to support the annotation of multimedia content. Automatic generation of annotations for multimedia involves high-level semantic representation and machine learning to ensure accuracy of annotation. Content-based retrieval techniques can be employed to generate the metadata, which can be used further by the text-based retrieval.

Establishment of Standard Evaluation Paradigm and Test-Bed

The National Institute of Standards and Technology (NIST) has developed TREC (Text REtrieval Conference) as the standard test-bed and evaluation paradigm for the information retrieval community. In response to the research needs from the video retrieval community, the TREC released a video track in 2003, which became an independent evaluation (called TRECVID) (Smeaton, 2003). In music information retrieval, a formal resolution expressing a similar need was passed in 2001, requesting a TREC-like standard test-bed and evaluation paradigm (Downie, 2003). The image retrieval community still awaits the construction and implementation of a scientifically valid evaluation framework and standard test bed.

Embedding Relevance Feedback

Multimedia contains large quantities of rich information and involves the subjectivity of human perception. The design of content-based retrieval systems has turned out to emphasize an interactive approach instead of a computer-centric approach. A user interaction approach requires human and computer to interact in refining the high-level queries. Relevance feedback is a powerful technique used for facilitating interaction between the user and the system. The research issue includes the design of the interface with regard to usability and learning algorithms, which can dynamically update the weights embedded in the query object

to model the high-level concepts and perceptual subjectivity.

Bridging the Semantic Gap

One of the main challenges in multimedia retrieval is bridging the gap between low-level representations and high-level semantics (Lew & Eakins, 2002). The semantic gap exists because low-level features are more easily computed in the system design process, but high-level queries are used at the starting point of the retrieval process. The semantic gap is not only the conversion between low-level features and high-level semantics, but it is also the understanding of contextual meaning of the query involving human knowledge and emotion. Current research intends to develop mechanisms or models that directly associate the high-level semantic objects and representation of low-level features.

CONCLUSION

The main contributions in this article were to provide a conceptual architecture for content-based multimedia retrieval, to discuss the system design issues, and to point out some potential problems in individual components. Finally, some research issues and future trends were identified and addressed.

The ideal content-based retrieval system from a user's perspective involves the semantic level. Current content-based retrieval systems generally make use of low-level features. The semantic gap has been a major obstacle for content-based retrieval. Relevance feedback is a promising technique to bridge this gap. Due to the efforts of the research community, a few systems have started to employ high-level features and are able to deal with some semantic queries. Therefore, more intelligent content-based retrieval systems can be expected in the near future.

KEY TERMS

Boolean Query: A query that uses Boolean operators (AND, OR, and NOT) to formulate a complex condition. A Boolean query example can be "university" OR "college."

Content-Based Retrieval: An application that directly makes use of the contents of media rather than annotation inputted by the human to locate desired data in large databases.

Feature Extraction: A subject of multimedia processing that involves applying algorithms to calculate and extract some attributes for describing the media.

Query by Example: A method of searching a database using example media as search criteria. This mode allows the users to select predefined examples requiring the users to learn the use of query languages.

Relevance Feedback: A technique that requires users to identify positive results by labeling those that are relevant to the query and subsequently analyzes the user's feedback using a learning algorithm.

Semantic Gap: The difference between the high-level user perception of the data and the lower-level representation of the data used by computers. As high-level user perception involves semantics that cannot be translated directly into logic context, bridging the semantic gap is considered a challenging research problem.

Similarity Measure: A measure that compares the similarity of any two objects represented in the multi-dimensional space. The general approach is to represent the data features as multi-dimensional points and then to calculate the distances between the corresponding multi-dimensional points.

Chapter 2.2
MM4U:
A Framework for Creating Personalized Multimedia Content

Ansgar Scherp
OFFIS Research Institute, Germany

Susanne Boll
University of Oldenburg, Germany

ABSTRACT

In the Internet age and with the advent of digital multimedia information, we succumb to the possibilities that the enchanting multimedia information seems to offer, but end up almost drowning in the multimedia information: Too much information at the same time, so much information that is not suitable for the current situation of the user, too much time needed to find information that is really helpful. The multimedia material is there, but the issues of how the multimedia content is found, selected, assembled, and delivered such that it is most suitable for the user's interest and background, the user's preferred device, network connection, location, and many other settings, is far from being solved. In this chapter, we are focusing on the aspect of how to assemble and deliver personalized multimedia content to the users. We present the requirements and solutions of multimedia content modeling and multimedia content authoring as we find it today. Looking at the specific demands of creating personalized multimedia content, we come to the conclusion that a dynamic authoring process is needed in which just in time the individual multimedia content is created for a specific user or user group. We designed and implemented an extensible software framework, MM4U (short for "MultiMedia for you"), which provides generic functionality for typical tasks of a dynamic multimedia content personalization process. With such a framework at hand, an application developer can concentrate on creating personalized content in the specific

domain and at the same time is relieved from the basic task of selecting, assembling, and delivering personalized multimedia content. We present the design of the MM4U framework in detail with an emphasis for the personalized multimedia composition and illustrate the framework's usage in the context of our prototypical applications.

INTRODUCTION

Multimedia content today can be considered as the composition of different media elements, such as images and text, audio, and video, into an interactive multimedia presentation like a guided tour through our hometown Oldenburg. Features of such a presentation are typically the temporal arrangement of the media elements in the course of the presentation, the layout of the presentation, and its interaction features. *Personalization* of multimedia content means that the multimedia content is targeted at a specific person and reflects this person's individual context, specific background, interest, and knowledge, as well as the heterogeneous infrastructure of end devices to which the content is delivered and on which it is presented. The creation of personalized multimedia content means that for each intended context a custom presentation needs to be created. Hence, multimedia content personalization is the shift from one-size-fits-all to a very individual and personal one-to-one provision of multimedia content to the users. This means in the end that the multimedia content needs to be prepared for each individual user. However, if there are many different users that find themselves in very different contexts, it soon becomes obvious that a manual creation of different content for all the different user contexts is not feasible, let alone economical (see André & Rist, 1996). Instead, a *dynamic*, automated process of selecting and assembling personalized multimedia content depending on the user context seems to be reasonable.

The creation of multimedia content is typically subsumed under the notion of multimedia authoring. However, such authoring today is seen as the static creation of multimedia content. Authoring tools with graphical user interfaces (GUI) allow us to manually create content that is targeted at a specific user group. If the content created is at all "personalizable," then only within a very limited scope. First research approaches in the field of dynamic creation of personalized multimedia content are promising; however, they are often limited to certain aspects of the content personalization to the individual user. Especially when the content personalization task is more complex, these systems need to employ additional programming. As we observe that programming is needed in many cases anyway, we continue this observation consequently and propose MM4U (short for "MultiMedia for you"), a component-based object-oriented software framework to support the software development process of multimedia content personalization applications. MM4U relieves application developers from general tasks in the context of multimedia content personalization and lets them concentrate on the application domain-specific tasks. The framework's components provide generic functionality for typical tasks of the multimedia content personalization process. The design of the framework is based on a comprehensive analysis of the related approaches in the field of user profile modeling, media data modeling, multimedia composition, and multimedia presentation formats. We identify the different tasks that arise in the context of creating personalized multimedia content. The different components of the framework support these different tasks for creating user-centric multimedia content: They integrate the generic access to user profiles, media data, and associated meta data, provide support for personalized multimedia composition and layout, as well as create the context-aware multimedia presentations. With such a framework, the devel-

opment of multimedia applications becomes easier and much more efficient for different users with their different (semantic) contexts. On the basis of the MM4U framework, we are currently developing two sample applications: a personalized multimedia sightseeing tour and a personalized multimedia sports news ticker. The experiences we gain from the development of these applications give us important feedback on the evaluation and continuous redesign of the framework.

The remainder of this chapter is organized as follows: To review the notion of multimedia content authoring, in Multimedia Content Authoring Today we present the requirements of multimedia content modeling and the authoring support we find today. Setting off from this, Dynamic Authoring of Personalized Content introduces the reader to the tasks of creating personalized multimedia content and why such content can be created only in a dynamic fashion. In Related Approaches, we address the related approaches we find in the field before we present the design of our MM4U framework in The Multimedia Personalization Framework section. As the personalized creation of multimedia content is a central aspect of the framework, Creating Personalized Multimedia Content presents in detail the multimedia personalization features of the framework. Impact of Personalization to The Development of Multimedia Applications shows how the framework supports application developers and multimedia authors in their effort to create personalized multimedia content. The implementation and first prototypes are presented in Implementation and Prototypical Applications before we come to our summary and conclusion in the final section.

MULTIMEDIA CONTENT AUTHORING TODAY

In this section, we introduce the reader to current notions and techniques of multimedia content modeling and multimedia content authoring. An understanding of requirements and approaches in modeling and authoring of multimedia content is a helpful prerequisite to our goal, the dynamic creation of multimedia content. For the modeling of multimedia content we present our notion of multimedia content, documents, and presentation and describe the central characteristics of typical multimedia document models in the first subsection. For the creation of multimedia content, we give a short overview of directions in multimedia content authoring today in the second subsection.

Multimedia Content

Multimedia content today is seen as the result of a composition of different media elements (media content) in a continuous and interactive multimedia presentation. Multimedia content builds on the modeling and representation of the different media elements that form the building bricks of the composition. A multimedia document represents the composition of continuous and discrete media elements into a logically coherent multimedia unit. A multimedia document that is composed in advance to its rendering is called preorchestrated in contrast to compositions that take place just before rendering that are called live or *on-the-fly*. A multimedia document is an instantiation of a *multimedia document model* that provides the primitives to capture all aspects of a multimedia document. The power of the multimedia document model determines the degree of the multimedia functionality that documents following the model can provide. Representatives of (abstract) multimedia document models in research can be found with CMIF (Bulterman et al., 1991), Madeus (Jourdan et al., 1998), Amsterdam Hypermedia Model (Hardman, 1998; Hardman et al., 1994a), and ZYX (Boll & Klas, 2001). A *multimedia document format* or *multimedia presentation format* determines the representation of a multimedia document for the document's

exchange and rendering. Since every multimedia presentation format implicitly or explicitly follows a multimedia document model, it can also be seen as a proper means to "serialize" the multimedia document's representation for the purpose of exchange. Multimedia presentation formats can either be standardized, such as the W3C standard SMIL (Ayars et al., 2001), or proprietary such as the widespread Shockwave file format (SWF) of Macromedia (Macromedia, 2004). A *multimedia presentation* is the rendering of a multimedia document. It comprises the continuous rendering of the document in the target environment, the (pre)loading of media data, realizing the temporal course, the temporal synchronization between continuous media streams, the adaptation to different or changing presentation conditions and the interaction with the user.

Looking at the different models and formats we find, and also the terminology in the related work, there is not necessarily a clear distinction between multimedia document models and multimedia presentation formats, and also between multimedia documents and multimedia presentations. In this chapter, we distinguish the notion of multimedia document models as the definition of the abstract composition capabilities of the model; a multimedia document is an instance of this model. The term *multimedia content* or *content representation* is used to abstract from existing formats and models, and generally addresses the composition of different media elements into a coherent multimedia presentation. Independent of the actual document model or format chosen for the content, one can say that a multimedia content representation has to realize at least three central aspects: the temporal, spatial, and interactive characteristics of a multimedia presentation (Boll et al., 2000). However, as many of today's concrete multimedia presentation formats can be seen as representing both a document model and an exchange format for the final rendering of the document, we use these as an illustration of the central aspects of multimedia documents. We present an overview of these characteristics in the following listing; for a more detailed discussion on the characteristics of multimedia document models we refer the reader to (Boll et al., 2000; Boll & Klas, 2001).

- A *temporal model* describes the temporal dependencies between media elements of a multimedia document. With the temporal model, the temporal course such as the parallel presentation of two videos or the end of a video presentation on a mouse-click event can be described. One can find four types of temporal models: *point-based* temporal models, *interval-based* temporal models (Little & Ghafoor, 1993; Allen, 1983), *enhanced interval-based* temporal models that can handle time intervals of unknown duration (Duda & Keramane, 1995; Hirzalla et al., 1995; Wahl & Rothermel, 1994), *event-based* temporal models, and *script-based* realization of temporal relations. The multimedia presentation formats we find today realize different temporal models, for example, SMIL 1.0 (Bugaj et al., 1998) provides an interval-based temporal model only, while SMIL 2.0 (Ayars et al., 2001) also supports an event-based model.
- For a multimedia document not only the temporal synchronization of these elements is of interest but also their spatial positioning on the presentation media, for example, a window, and possibly the spatial relationship to other visual media elements. The positioning of a visual media element in the multimedia presentation can be expressed by the use of a *spatial model.* With it one can, for example, place one image about a caption or define the overlapping of two visual media. Besides the arrangement of media elements in the presentation, also the visual layout or design is defined in the presentation. This can range from a simple setting for background colors and fonts up

to complex visual designs and effects. In general, three approaches to spatial models can be distinguished: *absolute positioning*, *directional relations* (Papadias et al., 1995; Papadias & Sellis, 1994), and *topological relations* (Egenhofer & Franzosa, 1991). With absolute positioning we subsume both the placement of a media element at an absolute position with respect to the origin of the coordinate system and the placement at an absolute position relative to another media element. The absolute positioning of media elements can be found, for example, with Flash (Macromedia, 2004) and the Basic Language Profile of SMIL 2.0, whereas the relative positioning is realized, for example, by SMIL 2.0 and SVG 1.2 (Andersson et al., 2004b).

- A very distinct feature of a multimedia document model is the ability to specify *user interaction* in order to let a user choose between different presentation paths. Multimedia documents without user interaction are not very interesting as the course of their presentation is exactly known in advance and, hence, could be recorded as a movie. With interaction models a user can, for example, select or repeat parts of presentations, speed up a movie presentation, or change the visual appearance. For the modeling of user interaction, one can identify at least three basic types of interaction: *navigational interactions*, *design interactions*, and *movie interactions*. Navigational interaction allows the selection of one out of many presentation paths and is supported by all the considered multimedia document models and presentation formats.

Looking at existing multimedia document models and presentation formats both in industry and research, one can see that these aspects of multimedia content are implemented in two general ways: The standardized formats and research models typically implement these aspects in different variants in a structured (XML) fashion as can be found with SMIL 2.0, HTML+TIME (Schmitz et al., 1998), SVG 1.2, Madeus, and ZYX. Proprietary approaches, however, represent or program these aspects in an adequate internal model such as Macromedia's Shockwave format. Independent of the actual multimedia document model, support for the *creation* of these documents is needed — multimedia content authoring. We will look at the approaches we find in the field of multimedia content authoring in the next section.

Multimedia Authoring

While multimedia content represents the composition of different media elements into a coherent multimedia presentation, *multimedia content authoring* is the process in which this presentation is actually created. This process involves parties from different fields including media designers, computer scientists, and domain experts: Experts from the domain provide their knowledge in the field; this knowledge forms the input for the creation of a storyboard for the intended presentation. Such a storyboard forms often the basis on which creators and directors plan the implementation of the story with the respective media and with which writers, photographers, and camerapersons acquire the digital media content. Media designers edit and process the content for the targeted presentation. Finally, multimedia authors compose the preprocessed and prepared material into the final multimedia presentation. Even though we described this as a sequence of steps, the authoring process typically includes cycles. In addition, the expertise for some of the different tasks in the process can also be held by one single person. In this chapter, we are focusing on the part of the multimedia content creation process in which the prepared material is actually assembled into the final multimedia presentation.

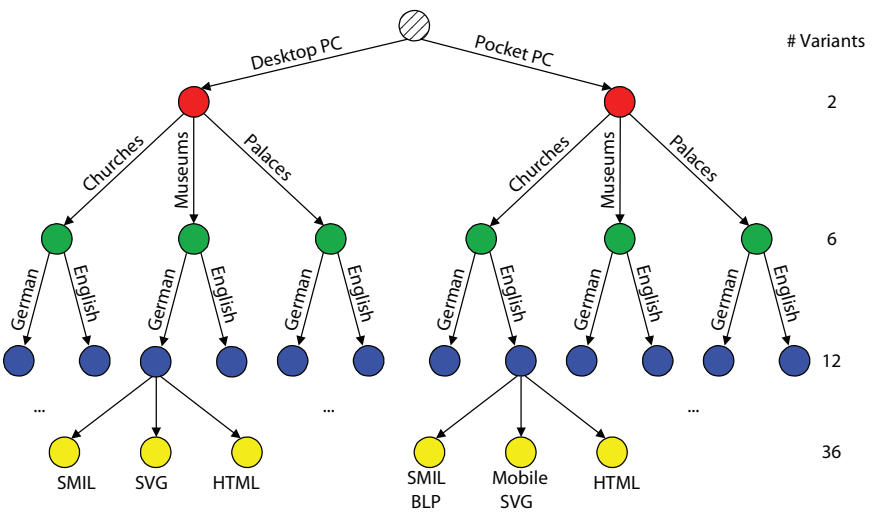
This part is typically supported by professional multimedia development programs, so-called

authoring tools or authoring software. Such tools allow the composition of media elements into an interactive multimedia presentation via a graphical user interface. The authoring tools we find here range from domain expert tools to general purpose authoring tools.

- Domain expert tools hide as much as possible the technical details of content authoring from the authors and let them concentrate on the actual creation of the multimedia content. The tools we find here are typically very specialized and targeted at a very specific domain. An example for such a tool has been developed in the context of our previous research project Cardio-OP (Klas et al., 1999) in the domain of cardiac surgery. The content created in this project is an interactive multimedia book about topics in the specialized domain of cardiac surgery. Within the project context, an easy-to-use authoring wizard was developed to allow medical doctors to easily create "pages" of a multimedia book in cardiac surgery. The Cardio-OP-Wizard guides the domain experts through the authoring process by a digital storyboard for a multimedia book on cardiac surgery. The wizard hides as much technical detail as possible.
- On the other end of the spectrum of authoring tools we find highly generalized tools such as Macromedia Director (Macromedia, 2004). These tools are independent of the domain of the intended presentation and let the authors create very sophisticated multimedia presentations. However, the authors typically need to have high expertise in using the tool. Very often programming in an integrated programming language is needed to achieve special effects or interaction patterns. Consequently, the multimedia authors need programming skills and along with this some experience in software development and software engineering.

Whereas a multimedia document model has to represent the different aspects of time, space, and interaction, multimedia authoring tools must allow the authors to actually assemble the multimedia content. However, the authors are normally experts from a specific domain. Consequently, the only authoring tools that are practicable to create

Figure 1. Example of the variation possibilities within a personalized city guide application



multimedia content for a specific domain are those that are highly specialized and easy to use.

DYNAMIC AUTHORING OF PERSONALIZED CONTENT

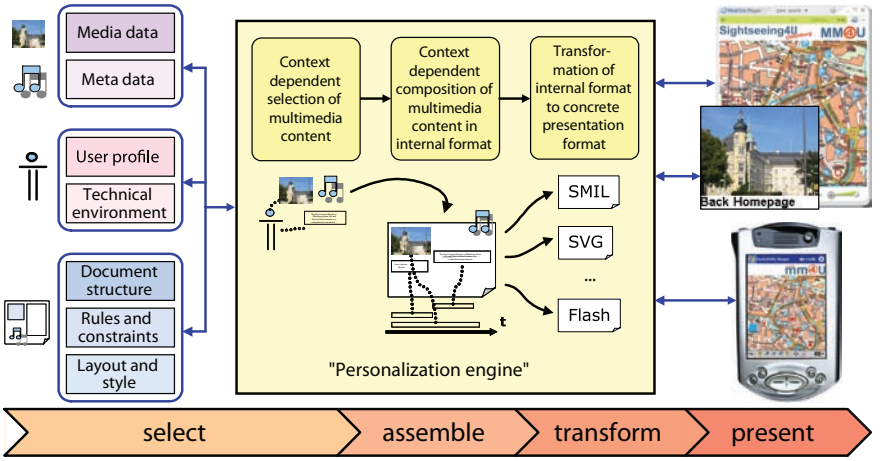
The authoring process described above so far represents a manual authoring of multimedia content, often with high effort and cost involved. Typically, the result is a multimedia presentation targeted at a certain user group in a special technical context. However, the one-size-fits-all fashion of the multimedia content created does not necessarily satisfy different users' needs. Different users may have different preferences concerning the content and also may access the content in networks on different end devices. For a wider applicability, the authored multimedia content needs to "carry" some alternatives that can be exploited to adapt the presentation to the specific preferences of the users and their technical settings. Figure 1 shows an illustration of the variation possibilities that a simple personalized city guide application can possess. The root of the tree represents the multimedia presentation for the personalized city tour. If this presentation was intended for both Desktop PC and PDA, this results in two variants of the presentation. If then some tourists are interested only in churches, museums, or palaces and would like to receive the content in either English or German, this already sums up to 12 variants. If then the multimedia content should be available in different presentation formats, the number of variation possibilities within a personalized city tour increases again. Even though different variants are not necessarily entirely different and may have overlapping content, the example is intended to illustrate that the flexibility of multimedia content to personalize to different user contexts quickly leads to an explosion of different options. And still the content can only be personalized within the flexibility range that has been anchored in the content.

From our point of view, an efficient and competitive creation of personalized multimedia content can only come from a system approach that supports the *dynamic* authoring of personalized multimedia content. A dynamic creation of such content allows for a selection and composition of just those media elements that are targeted at the user's specific interest and preferences. Generally, the dynamic authoring comprises the steps and tasks that occur also with static authoring, but with the difference that the creation process is postponed to the time when the targeted user context and the presentation is created for this specific context. To be able to efficiently create presentations for (m)any given contexts, a manual authoring of a presentation meeting the user needs is not an option; instead, a dynamic content creation is needed.

As we look into the process of *dynamic authoring* of personalized multimedia content, it is apparent that this process involves different phases and tasks. We identify the central tasks in this process that need to be supported by a suitable solution for personalized content creation.

Figure 2 depicts the general process of creating personalized multimedia content. The core of this process is an application we call *personalization engine*. The input parameters to this engine can be characterized by three groups: The first group of input parameters is the media elements with the associated meta data that constitute the content from which the personalized multimedia presentations are selected and assembled. The second group enfolds the user's personal and technical context. The user profile includes information about, for example, the user's current task, the location, and environment, like weather and loudness, his or her knowledge, goals, preferences and interests, abilities and disabilities, as well as demographic data. The technical context is described by the type of the user's end device, the hardware and software characteristics, as for example the available amount of memory and media player, as well as possible network connections and input devices.

Figure 2. General process of personalizing multimedia content



The third group of input parameters influences the general structure of the resulting personalized multimedia presentation and subsumes other preferences a user could have for the multimedia presentation.

Within the personalization engine, these input parameters are now used to author the personalized multimedia presentation. First, the personalization engine exploits all available information about the user's context and his or her end device to select by means of media meta data those media elements that are of most relevance according to the user's interests and preferences and meet the characteristics of the end device at the best. In the next step, the selected media elements are assembled and arranged by the personalization engine — again in regard to the user profile information and the characteristics of the end device — to the personalized multimedia content, represented in an *internal document model* (Scherp & Boll, 2004b). This internal document model abstracts from the different characteristics of today's multimedia presentation formats and, hence, forms the greatest common denominator of these formats. Even though our abstract model does not reflect the fancy features of some of today's multimedia presentation formats, it supports the very central multimedia features of modeling time, space, and interaction. It is designed to be efficiently transformed to the concrete syntax of the different presentation formats. For the assembly, the personalization engine uses the parameters for document structure, the layout and style parameters, and other rules and constraints that describe the structure of the personalized multimedia presentation, to determine among others the temporal course and spatial layout of the presentation. The center of Figure 2 sketches this temporal and spatial arrangement of selected media elements over time in a spatial layout following the document structure and other preferences. Only then in the transformation phase, the multimedia content in the internal document model is transformed to a concrete presentation format. Finally, the just generated personalized multimedia presentation is rendered and displayed by the actual end device.

RELATED APPROACHES

In this section we present the related approaches in the field of personalized multimedia content creation. We first discuss the creation of personalizable multimedia content with today's authoring environments before we come to research approaches that address a *dynamic* composition of adapted or personalized multimedia content.

Multimedia authoring tools like Macromedia Director (Macromedia, 2004) today require high expertise from their users and create multimedia presentations that are targeted only at a specific user or user group. Everything "personalizable" needs to be programmed or scripted within the tool's programming language. Early work in the field of creating advanced hypermedia and multimedia documents can be found, for example, with the Amsterdam Hypermedia Model (Hardman, 1998; Hardman et al., 1994b) and the authoring system CMIFed (van Rossum, 1993; Hardman et al., 1994a) as well as with the ZYX (Boll & Klas, 2001) multimedia document model and a domain-specific authoring wizard (Klas et al., 1999). In the field of standardized models, the declarative description of multimedia documents with SMIL allows for the specification of adaptive multimedia presentations by defining presentation alternatives by using the "switch" element. A manual authoring of such documents that are adaptable to many different contexts is too complex; also the existing authoring tools such as GR*i*NS editor for SMIL from Oratrix (Oratrix, 2004) are still tedious to handle. Some SMIL tools provide support for the "switch" element to define presentation alternatives; a comfortable interface for editing the different alternatives for many different contexts, however, is not provided. Consequently, we have been working on the approach in which a multimedia document is authored for one general context and is then "automatically" enriched by the different presentation alternatives needed for the expected user contexts in which the document is to be viewed (Boll et al., 1999). However, this approach is reasonable only for a limited number of presentation alternatives and limited presentation complexity in general.

Approaches that *dynamically* create personalized content are typically found on the Web, for example, Amazon.com (Amazon, 1996-2004) or MyYahoo (Yahoo!, 2002). However, these systems remain text-centric and are not occupied with the complex composition of media data in time and space into real multimedia presentations. On the pathway to an automatic generation of *personalized* multimedia presentations, we primarily find research approaches that address personalized *media* presentations only: For example, the home-video editor Hyper-Hitchcock (Girgensohn et al., 2003; Girgensohn et al., 2001) provides a preprocessing of a video such that users can interactively select clips to create their personal video summary. Other approaches create summaries of music or video (Kopf et al., 2004; Agnihotri et al., 2003). However, the systems provide an intelligent and intuitive access to large sets of (continuous) media rather than a dynamic creation of individualized content. An approach that addresses personalization for videos can be found, for example, with IBM's Video Semantic Summarization System (IBM Corporation, 2004a) which is, however, still concentrating on one single media type.

Towards *personalized multi*media we find interesting work in the area of *adaptive hypermedia* systems which has been going on for quite some years now (Brusilovsky 1996; Wu et al., 2001; De Bra et al., 1999a, 2000, 2002b; De Carolis et al., 1998, 1999). The adaptive hypermedia system AHA! (De Bra et al., 1999b, 2002a, 2003) is a prominent example here which also addresses the authoring aspect (Stash & De Bra, 2003), for example, in adaptive educational hypermedia applications (Stash et al., 2004). However, though these and further approaches integrate media elements in their adaptive hypermedia presentations, synchronized multimedia presentations are not in their focus.

Personalized or adaptive *user interfaces* allow the navigation and access of information and services in a customized or personalized fashion. For example, work done in the area of personalized agents and avatars considers "presentation generation" exploiting natural language generation and visual media elements to animate the agents and avatars (de Rosis et al., 1999). These approaches address the human computer interface; the general issue of dynamically creating arbitrary personalized multimedia content that meets the user's information needs is not in their research focus.

A very early approach towards the dynamic creation of multimedia content is the Coordinated Multimedia Explanation Testbed (COMET), which is based on an expert-system and different knowledge databases and uses constraints and plans to actually generate the multimedia presentations (Elhadad et al., 1991; McKeown et al., 1993). Another interesting approach to automate the multimedia authoring process has been developed at the DFKI in Germany by the two knowledge-based systems, WIP (Knowledge-based Presentation of Information) and PPP (Personalized Plan-based Presenter). WIP is a knowledge-based presentation system that automatically generates instructions for the maintenance of technical devices by plan generation and constraint solving. PPP enhances this system by providing a lifelike character to present the multimedia content and by considering the temporal order in which a user processes a presentation (André, 1996; André & Rist, 1995,1996). Also a very interesting research approach towards the dynamic generation of multimedia presentations is the Cuypers system (van Ossenbruggen et al., 2000) developed at the CWI. This system employs constraints for the description of the intended multimedia programming and logic programming for the generation of a multimedia document (CWI, 2004). The multimedia document group at INRIA in France developed within the Opéra project a generic architecture for the automated construction of multimedia presentations based on transformation sheets and constraints (Villard, 2001). This work is continued within the succeeding project Web, Accessibility, and Multimedia (WAM) with the focus on a negotiation and adaptation architecture for multimedia services for mobile devices (Lemlouma & Layaïda, 2003, 2004).

However, we find limitations with existing systems when it comes to their expressiveness and flexible personalized content creation support. Many approaches for personalization are targeted at a specific application domain in which they provide a very specific content personalization task. The existing research solutions typically use a declarative description like rules, constraints, style sheets, configuration files, and the like to express the dynamic, personalized multimedia content creation. However, they can solve only those presentation generation problems that can be covered by such a declarative approach; whenever a complex and application-specific personalization generation task is required, the systems find their limit and need additional programming to solve the problem. Additionally, the approaches we find usually rely on fixed data models for describing user profiles, structural presentation constraints, technical infrastructure, rhetorical structure, and so forth, and use these data models as an input to their personalization engine. The latter evaluates the input data, retrieves the most suitable content, and tries to most intelligently compose the media into a coherent aesthetic multimedia presentation. A change of the input data models as well as an adaptation of the presentation generator to more complex presentation generation tasks is difficult if not unfeasible. Additionally, for these approaches the border between the declarative descriptions for describing content personalization constraints and the additional programming needed is not clear and differs from solution to solution. This leads us to the development of a software framework that supports the development of personalized multimedia applications.

MULTIMEDIA PERSONALIZATION FRAMEWORK

Most of the research approaches presented above apply to text-centered information only, are limited with regard to the "personalizability", or are targeted at very specific application domains. As mentioned above, we find that existing research solutions in the field of multimedia content personalization provide interesting solutions. They typically use a declarative description like style sheets, transformation rules, presentation constraints, configuration files, and the like to express the dynamic, personalized multimedia content creation. However, they can solve only those presentation generation problems that can be covered by such a declarative approach; whenever a complex and application-specific personalization generation task is required, the systems find their limit and need additional programming to solve the problem. To provide application developers with a general, domain independent support for the creation of personalized multimedia content we pursue a software engineering approach: the MM4U framework. With this framework, we propose a component-based object-oriented software framework that relieves application developers from general tasks in the context of multimedia content personalization and lets them concentrate on the application domain-specific tasks. It supports the dynamic generation of arbitrary personalized multimedia presentations and therewith provides substantial support for the development of personalized multimedia applications. The framework does not reinvent multimedia content creation but incorporates existing research in the field and also can be extended by domain and application-specific solutions. In the following subsection we identify by an extensive study of related work and our own experiences the general design goals of this framework. In the next subsection, we present the general design of the MM4U framework, and then we present a detailed insight into the framework's layered architecture in the last subsection.

General Design Goals for the MM4U Framework

The overall goal of MM4U is to simplify and to reduce the costs of the development process of personalized multimedia applications. Therefore, the MM4U framework has to provide the developers with support for the different tasks of the multimedia personalization process as shown in Figure 2. These tasks comprise assistance for the access to media data and associated meta data as well as user profile information and the technical characteristics of the end device. The framework must also provide for the selection and composition of media elements into a coherent multimedia presentation. Finally, the personalized multimedia content must be created for delivery and rendering on the user's end device.

In regard to these different tasks, we conducted an extensive study of related work: In the area of user profile modeling we considered among others Composite Capability/Preference Profile (Klyne et al., 2003), FIPA Device Ontology Specification (Foundation for Intelligent Physical Agents, 2002), User Agent Profile (Open Mobile Alliance, 2003), Customer Profile Exchange (Bohrer & Holland, 2004), (Fink et al., 1997), and (Chen & Kotz, 2000). In regard to meta data modeling, we studied different approaches of modeling meta data and approaches for meta data standards for multimedia, for example, Dublin Core (Dublin Core Metadata Initiative, 1995-2003) and Dublin Core Extensions for Multimedia Objects (Hunter, 1999), Resource Description Framework (Beckett & McBride, 2003), and the MPEG-7 Multimedia content description standard (ISO/IEC JTC 1/SC 29/WG 11, 1999, 2001a-e). For multimedia composition we analyzed the features of multimedia document models, including SMIL (Ayars et al., 2001), SVG (Andersson et al., 2004b), Macrome-

dia Flash (Macromedia, 2004), Madeus (Jourdan et al., 1998), and ZYX (Boll & Klas, 2001). For the presentation of multimedia content, respective multimedia presentation frameworks were regarded including Java Media Framework (Sun Microsystems, 2004), MET++ (Ackermann 1996), and PREMO (Duke et al., 1999). Furthermore, other existing systems and general approaches for creating personalized multimedia content that were considered including the Cuypers engine (van Ossenbruggen et al., 2000) and the Standard Reference Model for Intelligent Multimedia Presentation Systems (Bordegoni et al., 1997).

We also derived design requirements to the framework from first prototypes of personalized multimedia applications we developed in different fields such as a personalized sightseeing tour through Vienna (Boll, 2003), a personalized mobile paper chase game (Boll et al., 2003), and a personalized multimedia music newsletter.

From the extensive study of related work and the first experiences and requirements we gained from our prototypical applications, we developed the single layers of the framework. We also derived three general design goals for MM4U. These design goals are

- The framework is to be designed such that it is independent of any special application domain, that is, it can be used to generate arbitrary personalized multimedia content. Therefore, it provides general multimedia composition and personalization functionality and is flexible enough to be adapted and extended concerning the particular requirements of the concrete personalization functionalities a personalized application needs.
- The access to user profile information and media data with its associated meta data must be independent of the particular solutions for storage, retrieval, and processing of such data. Rather the framework should provide a unified interface for the access to existing solutions. With distinct interfaces for the access to user profile information and media data with associated meta data, it is the framework's task to use and exploit existing (research) profile and media storage systems for the personalized multimedia content creation.
- The third design goal for the framework is what we call presentation independence. The framework is to be independent of, for example, the technical characteristics of the end devices, their network connection, and the different multimedia output formats that are available. This means, that the framework can be used to generate equivalent multimedia content for the different users and output channels and their individual characteristics. This *multichannel usage* implies that the personalized multimedia content generation task is to be partitioned into a composition of the multimedia content in an internal *representation format* and its later transformation into arbitrary (preferably standardized) *presentation formats* that can be rendered and displayed by end devices.

These general design goals have a crucial impact on the structure of the multimedia personalization framework, which we present in the following section.

General Design of the MM4U Framework

A software framework like MM4U is a semifinished software architecture, providing a software system as a generic application for a specific domain (Pree, 1995). The MM4U framework comprises components, which are bound together by their interaction (Szyperski et al., 2002), and realizes generic support for personalized multimedia applications. Each component is realized as an

object-oriented framework and consists of a set of abstract and concrete classes. Depending on the usage of a framework, the so-called "white-box" and "black-box" frameworks can be distinguished (respectively, white-box and gray-box reuse). A framework is used as a black-box if the concrete application that uses the framework adapts its functionality by different compositions of the framework's classes. In this case the concrete application uses only the built-in functionality of the framework, that is, those modules with which the framework is already equipped. In contrast, the functionality of a white-box framework is refined or extended by a concrete application, by adding additional modules through inheritance of (abstract) classes. Between these two contrasts arbitrary "shades of gray" are possible (Szyperski et al., 2002). The design of the MM4U framework lies somewhere in the middle between pure black-box and pure white-box. Being a domain independent framework, MM4U needs to be configured and extended to meet the specific requirements of a concrete personalized multimedia application. The framework provides many modules, for example, to access media data and associated meta data, user profile information, and generates the personalized multimedia content in a standardized output format that can be reused for different application areas (black-box usage). For the very application-specific personalization functionality, the framework can be extended correspondingly (white-box usage).

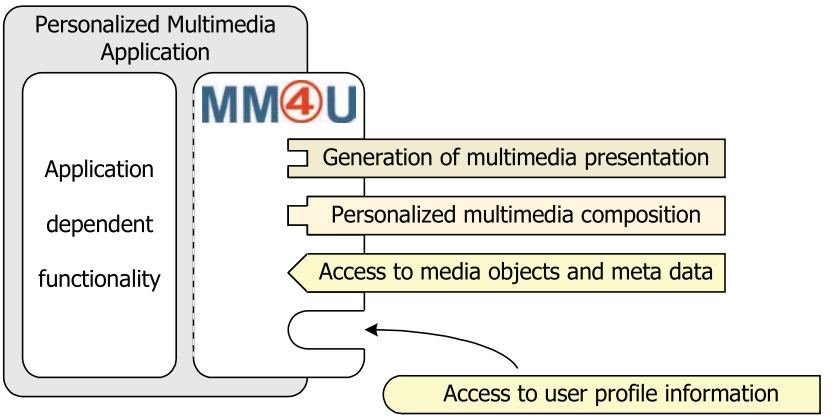
The usage of the MM4U framework by a concrete personalized multimedia application is illustrated schematically in Figure 3. The personalized multimedia application uses the functionality of the framework to create personalized multimedia content, and integrates it in whatever application dependent functionality is needed, either by using the already built-in functionality of the framework or by extending it for the specific requirements of the concrete personalized multimedia application.

With respect to the multimedia software development process the MM4U framework assists the computer scientists during the design and implementation phase. It alleviates the time-consuming multimedia content assembly task and lets the computer scientists concentrate on the development of the actual application. The MM4U framework provides functionality for the single tasks of the personalization engine as described in the section on Dynamic Authoring of Personalized Content. It offers the computer scientists support for integrating and accessing user profile information and media data, selecting media elements according to the user's profile information, composing these elements into coherent multimedia content, and generating this content in standardized multimedia document formats to be presented on the user's end device.

When designing a framework, the challenge is to identify the points where the framework should be flexible, that is, to identify the semantic aspects of the framework's application domain that have to be kept flexible. These points are the so-called *hot spots* and represent points or sockets of the intended flexibility of a framework (Pree, 1995). Each hot spot constitutes a well-defined interface where proper modules can be plugged in. When designing the MM4U framework we identified hot spots where adequate modules for supporting the personalization task can be plugged in that provide the required functionality.

As depicted in Figure 3, the MM4U framework provides four types of such hot spots, where different types of modules can be plugged in. Each hot spot represents a particular task of the personalization process. The hot spots can be realized by plugging in a module that implements the hot spot's functionality for a concrete personalized multimedia application. These modules can be both application-dependent and application-independent. For example, the access to media data and associated meta data is not necessarily application-dependent, whereas the composition

Figure 3. Usage of the MM4U framework by a personalized multimedia application



of personalized multimedia content can be heavily dependent on the concrete application.

After the general design of the framework, we take a closer look at the concrete architecture of MM4U and its components in the next section.

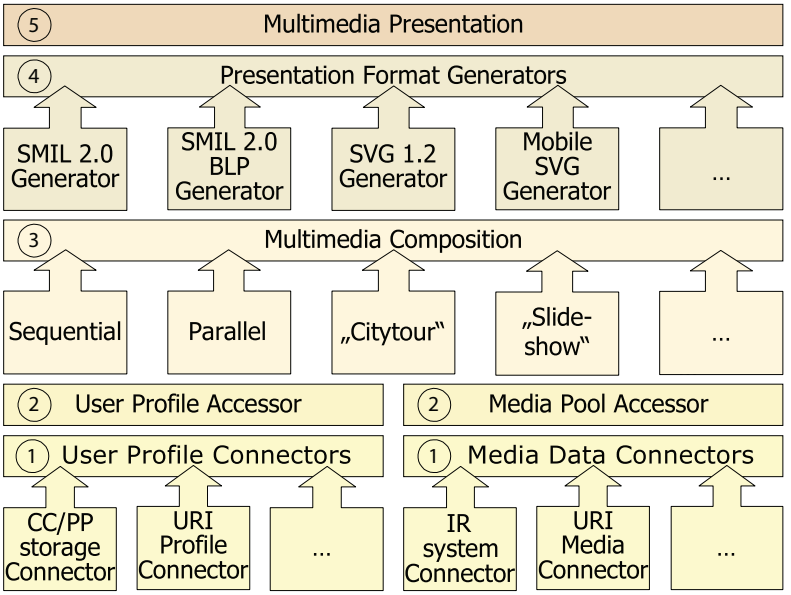
Design of the Framework Layers

For supporting the different tasks of the multimedia personalization process, which are the access to user profile information and media data, selection and composition of media elements into a coherent presentation, rendering and display of the multimedia presentation on the end device, a layered architecture seems to be best suited for MM4U. The layered design of the framework is illustrated in Figure 4. Each layer provides modular support for the different tasks of the multimedia personalization process. The access to user profile information and media data are realized by the layers (1) and (2), followed by the two layers (3) and (4) in the middle for composition of the multimedia presentation in an internal object-oriented representation and its later transformation into a concrete presentation output format. Finally, the top layer (5) realizes the rendering and display of the multimedia presentation on the end device.

To be most flexible for the different requirements of the concrete personalized multimedia applications, the framework's layers allow extending the functionality of MM4U by embedding additional modules as indicated by the empty boxes with dots. In the following descriptions, the features of the framework are described along its different layers. We start from the bottom of the architecture and end with the top layer.

(1) *Connectors*: The User Profile Connectors and the Media Data Connectors bring the user profile data and media data into the framework. They integrate existing systems for user profile stores, media storage, and retrieval solutions. As there are many different systems and formats available for user profile information, the User Profile Connectors abstract from the actual access to and retrieval of user profile information and provide a unified interface to the profile information. With this component, the different formats and structures of user profile models can be made accessible via a unified interface. For example, a flexible URIProfileConnector we developed for our demonstrator applications gains access to

Figure 4. Overview of the multimedia personalization framework MM4U



user profiles over the Internet. These user profiles are described as hierarchical ordered key-value pairs. This is a quite simple model but already powerful enough to allow effective pattern-matching queries on the user profiles (Chen & Kotz, 2000). However, as shown in Figure 4 also a User Profile Connector for the access to, for example, a Composite Capability/Preference Profile (CC/PP) server could be plugged into the framework.

On the same level, the Media Data Connectors abstract from the access to media elements in different media storage and retrieval solutions that are available today with a unified interface. The different systems for storage and content-based retrieval of media data are interfaced by this component. For example the URIMediaConnector, we developed for our demonstrator applications, provides a flexible access of media objects and its associated meta data from the Internet via http or ftp protocols. The meta data is stored in a single index file, describing not only the technical characteristics of the media elements and containing the location where to find the media elements in the Internet, but also comprise additional information about them, for example, a short description of what is shown in a picture or keywords for which one can search. By analogy with the access to user profile information, another Media Data Connector plugged into the framework could provide access to other media and meta data sources, for example, an image retrieval (IR) system like IBM's QBIC (IBM Corporation, 2004b).

The Media Data Connector supports the query of media elements by the client application (client-pull) as well as the automatic notification of the personalized application when a new media object arises in the media

database (server-push). The latter is required, for example, by the personalized multimedia sports news ticker (see the section about Sports4U) which is based on a multimedia event space (Boll & Westermann, 2003).

(2) *Accessors*: The User Profile Accessor and the Media Pool Accessor provide the internal data model of the user profiles and media data information within the system. Via this layer the user profile information and media data needed for the desired content personalization are accessible and processable for the application. The Connectors and Accessors are designed such that they are *not* reinventing existing systems for user modeling or multimedia content management. They, rather, provide a seamless integration of the systems by distinct interfaces and comprehensive data models. In addition, when a personalized multimedia application uses more than one user profile database or media database, the Accessor layer encapsulates the resources so that the access to them is transparent to the client application.

While the following layer (3) to (5) each constitute single components within the MM4U framework, the Accessor layer and Connectors layer do not. Instead the left side and the right side of the layers (1) and (2), i.e., the User Profile Accessor and User Profile Connectors as well as the Media Pool Accessor and Media Data Connectors, each form one component in MM4U.

(3) *Multimedia Composition*: The Multimedia Composition component comprises abstract operators in compliance with the composition capabilities of multimedia composition models like SMIL, Madeus, and ZYX, which provide complex multimedia composition functionality. It employs the data from the User Profile Accessor and the Media Pool Accessor for the multimedia composition task. The Multimedia Composition component is developed as such that it enables to develop additional, possibly more complex or application-specific composition operators that can be seamlessly plugged-in into the framework. Result of the multimedia composition is an internal object-oriented representation of the personalized multimedia content independent of the different presentation formats.

(4) *Presentation Format Generators*: The Presentation Format Generators work on the internal object-oriented data model provided by the Multimedia Composition component and convert it into a standardized presentation format that can be displayed by the corresponding multimedia player on the client device. In contrast to the multimedia composition operators, the Presentation Format Generators are completely independent of the concrete application domain and only rely on the targeted output format. In MM4U, we have already developed Presentation Format Generators for SMIL 2.0, the Basic Language Profile (BLP) of SMIL 2.0 for mobile devices (Ayars et al., 2001), SVG 1.2, Mobile SVG 1.2 (Andersson et al., 2004a) comprising SVG Tiny for multimedia-ready mobile phones and SVG Basic for pocket computers like Personal Digital Assistants (PDA) and Handheld Computers (HHC), and HTML (Raggett et al., 1998). We are currently working on Presentation Format Generators for Macromedia Flash (Macromedia, 2004) and other multimedia document model formats including HTML+TIME, the 3GPP SMIL Language Profile (3rd Generation Partnership Project, 2003b), which is a subset of SMIL used for scene description within the Multimedia Messaging Service (MMS) interchange format (3rd Generation Partnership Project,

2003a), and XMT-Omega, a high-level abstraction of MPEG-4 based on SMIL (Kim et al., 2000).

(5) *Multimedia Presentation*: The Multimedia Presentation component on top of the framework realizes the interface for applications to actually play the presentation of different multimedia presentation formats. The goal here is to integrate existing presentation components of the common multimedia presentation formats like SMIL, SVG, or HTML+TIME which the underlying Presentation Format Generator produces. So the developers benefit from the fact that only players for standardized multimedia formats need to be installed on the user's end device and that they must not spend any time and resources in developing their own render and display engine for their personalized multimedia application.

The layered architecture of MM4U permits easy adaption for the particular requirements that can occur in the development of personalized multimedia applications. So special user profile connectors as well as media database connectors can be embedded into the Connectors layer of the MM4U framework to integrate the most diverse and individual solutions for storage, retrieval and gathering for user profile information and media data. With the ability to extend the Multimedia Composition layer by complex and sophisticated composition operators, arbitrary personalization functionality can be added to the framework. The Presentation Format Generator component allows integrating any output format into the framework to support most different multimedia players that are available for the different end devices.

The personalized selection and composition of media elements and operators into a coherent multimedia presentation is the central task of the multimedia content creation process which we present in more detail in the following section.

CREATING PERSONALIZED MULTIMEDIA CONTENT

The MM4U framework provides the general functionality for the dynamic composition of media elements and composition operators into a coherent personalized multimedia presentation. Having presented the framework layers in the previous section, we now look in more detail how the layers contribute to the different tasks in the general personalization process as shown in Figure 2. The Media Data Accessor layer provides the personalized selection of media elements by their associated meta data and is described in the next subsection. The Multimedia Composition layer supports the composition of media elements into time and space in the internal multimedia representation format in three different manners, which are presented in detail in the the next three subsections, and the final subsection describes the last step, the transformation of the multimedia content in internal document model to an output format that is actually delivered to and rendered by the client devices. This is supported by the Presentation Format Generators layer.

Personalized Multimedia Content Selection

For creating personalized multimedia content, first those media elements have to be selected from the media databases that are most relevant to the user's request. This personalized media selection is realized by the Media Data Accessor and Media Data Connector component of the framework. For the actual personalized selection of media elements, a context object is created within the Multimedia Composition layer carrying the user profile information, technical characteristics of the end device, and further application-specific information. With this context object, the unified interface of the Media Data Accessor for querying media elements is called. The context object is handed over to the concrete Media Data Connector

of the connected media database. Within the Media Data Connector, the context object is mapped to the meta data associated with the media elements in the database and those media elements are determined that match the request, that is, the given context object at best. It is important to note that the Media Data Accessor and Media Data Connector layer integrate and embrace existing multimedia information systems and modern content-based multimedia retrieval solutions. This means that the retrieval of the "best match" can only be left to the underlying storage and management systems. The framework can only provide for comprehensive and lean interfaces to these systems. This can be our own URIMediaServer accessed by the URIMediaConnector but also other multimedia databases or (multi)media retrieval solutions. The result set of the query is handed back by the Accessor to the composition layer.

For example, the context object for our mobile tourist guide application carries information about user interests and preferences with respect to the sights of the city, the display size of the end device, and the location for the tourist guide. The Media Data Connector, realized in this case by our URIMediaConnector, processes this context object and returns images and videos from those sights in Oldenburg that both match the user's interests and preferences as well as the limited display size of the mobile device.

Based on the personalized selection of media elements the Multimedia Composition layer provides the assembly of these media elements on three different manners, the basic, complex and sophisticated composition of multimedia content, which is described in the following sections.

Basic Composition Functionality

With the basic composition functionality the MM4U framework provides the basic bricks for composing multimedia content. It forms the basis for assembling the selected media elements into personalized multimedia documents and provides the means for realizing the central aspects of multimedia document models, that is, the temporal model, the spatial layout, and the interaction possibilities of the multimedia presentation. The temporal model of the multimedia presentation is determined by the temporal relationships between the presentation's media elements formed by the composition operators. The spatial layout expresses the arrangement and style of the visual media elements in the multimedia presentation. Finally, with the interaction model the user interaction of the multimedia presentation is determined, in order to let the user choose between different paths of a presentation. For the temporal model, we selected an interval-based approach as found in Duda & Keramane (1995). The spatial layout is realized by a hierarchical model for media positioning (Boll & Klas, 2001). For interaction with the user navigational and decision interaction are supported, as can be found with SMIL (Ayars et al., 2001) and MHEG-5 (Echiffre et al., 1998; International Organisation for Standardization, 1996).

A basic composition operator or *basic operator* can be regarded as an atomic unit for multimedia composition, which cannot be further broken down. Basic operators are quite simple but applicable for any application area and therefore most flexible. Basic temporal operators realize the temporal model, and basic interaction operators realize the interaction possibilities of the multimedia presentation, as specified above. The two basic temporal operators *Sequential* and *Parallel*, for example, can be used to present media elements one after the other in a sequence respectively to present media elements parallel at the same time. With basic temporal operators and media elements, the temporal course of the presentation can be determined like a slideshow as depicted in Figure 5. The operators are represented by white rectangles and the media elements by gray ones. The relation between the media elements and the basic operators is shown by the edges beginning with a filled circle at an operator and ending with

Figure 5. Slideshow as an example of assembled multimedia content

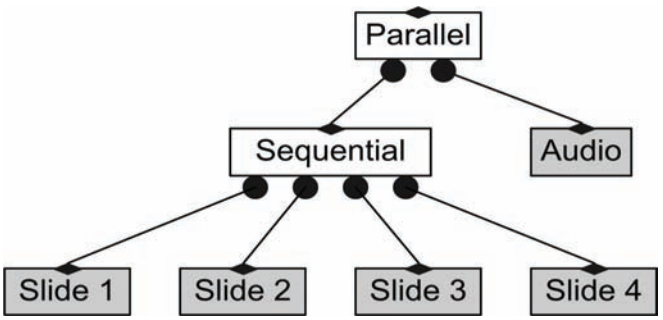


Figure 6. Adding layout to the slideshow example

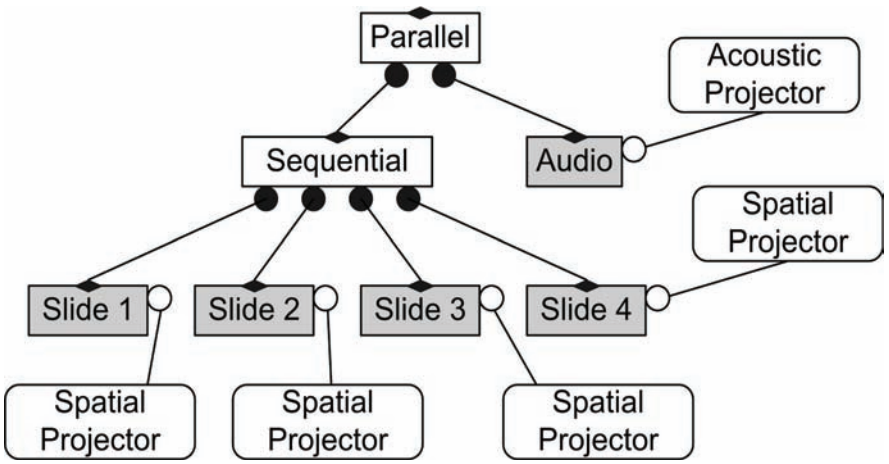


a filled rhombus respectively a diamond at a media element or another operator. The semantics of the slideshow shown in Figure 5 are that it starts with the presentation of the root element, which is the Parallel operator. The semantics of the Parallel operator are that it shows the operators and media elements that are attached to it at the same time. This means that the audio file starts to play while simultaneously the Sequential operator is presented. The semantics of the Sequential operator are to show the attached media elements one after another, so while the audio file is played in the background, the four slides are presented in sequence.

Besides the basic composition *operators*, the so-called *projectors* are part of the Multimedia Composition layer. Projectors can be attached to operators and media elements to define, for example, the visual and acoustical layout of the multimedia presentation. Figure 6 shows the

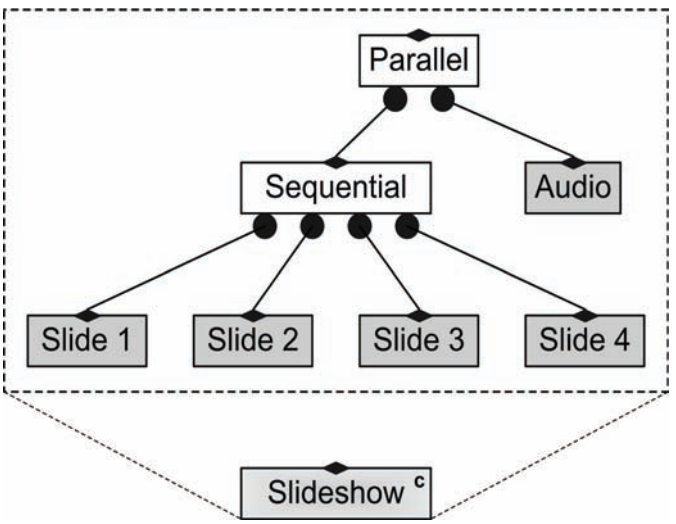
slideshow example from above with projectors attached. The spatial position as well as the width and height of the single slide media elements are determined by the corresponding *SpatialProjectors.* The volume, treble, bass, and balance of the audio medium is determined by the attached *AcousticProjector.*

Besides temporal operators, the Multimedia Composition component offers basic operators for specifying the interaction possibilities of the multimedia presentation. Interaction can be added, for example, by using the basic operator *InteractiveLink*. It defines a link represented by a single media element or a fragment of a multimedia presentation that is clickable by the user and a target presentation the user receives if he or she clicks on the link.

The description above presents some examples of the basic composition functionality the MM4U framework offers. The framework comprises customary composition operators for creating multimedia content as provided by modern multimedia presentation formats like SMIL and SVG. Even though the basic composition functionality does not reflect the fancy features of some of today's multimedia presentation formats, it supports the very central multimedia features of modeling time, space, and interaction. This allows the transformation of the internal document model into many different multimedia presentation formats for different end devices.

With the basic multimedia composition operators the framework offers, arbitrary multimedia presentations can be assembled. However, so far the MM4U framework provides "just" basic multimedia composition functionality. In the same way that one would use an authoring tool to create SMIL presentations, for example, the GR*i*NS editor (Oratrix, 2004), one can also use a corresponding authoring tool for the basic composition operators the MM4U framework offers to create multimedia content. For reasons of reusing parts of the created multimedia presentations, for example, a menu bar or a presentation's layout, and for convenience, there is a need for more complex and application-specific composition operators that provide a more convenient support for creating the multimedia content.

Figure 7. The slideshow examples as a complex composition operator

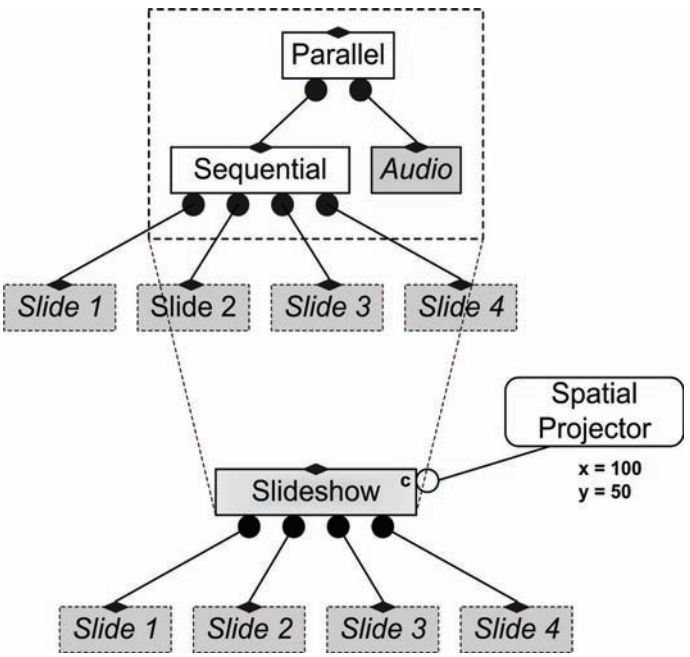


Complex Composition Functionality

For creating presentations that are more complex, the Multimedia Composition layer provides the ability to abstract from basic to complex operators. A complex composition operator encapsulates the composition functionality of an arbitrary number of basic operators and projectors and provides the developers with a more complex and application-specific building block for creating the multimedia content. Complex composition operators are composed of basic and others complex operators. As complex composition operators not only embed basic but also other complex operators, they provide for a reuse of composition operators. In contrast to the basic operators, the complex composition operators can be dismantled into their individual parts. Figure 7 depicts a complex composition operator for our slideshow example. It encapsulates the media elements, operators, and projectors of the slideshow (the latter are omitted in the diagram to reduce complexity). The complex operator *Slideshow*, indicated by a small "c" symbol in the upper right corner, represents an encapsulation of the former slideshow presentation in a complex object and forms itself a building block for more complex multimedia composition.

Complex operators, as described above, define fixed encapsulated presentations. Their temporal flow, spatial layout, and the used media elements cannot be changed subsequently. However, a complex composition operator does not necessarily need to specify all media elements, operators, and projectors of the respective multimedia document tree. Instead, to be more flexible, some parts can be intentionally left open. These parts constitute the parameters of a complex composition operator and have to be filled in for concrete usage of these operators. Such parameterized complex composition operators are one means to define *multimedia composition templates* within the MM4U framework. However, only prestructured multimedia content can be created with

Figure 8. The slideshow example as parameterized complex composition operator



these templates, since the complex composition operators can only encapsulate presentations of a fixed structure.

Figure 8 shows the slideshow example as a parameterized complex composition operator. In this case, the complex operator Slideshow comprises the two basic operators Parallel and Sequential. The Slideshow's parameters are the place holders for the single slides and have to be instantiated when the operator is used within the multimedia composition. The slideshow's audio file is already preselected. In addition, the parameters of a complex composition operator can be typed, that is, they expect a special type of operator or media element. The Slideshow operator would expect visual media elements for the parameters *Slide 1* to *Slide 4*. To indicate the complex operator's parameters, they are visualized by rectangles with dotted lines. The preselected audio file is already encapsulated in the complex operator as illustrated in Figure 7.

In the same way projectors are attached to basic operators in the basic composition functionality section, they can also be attached to complex operators. The SpatialProjector attached to the Slideshow operator shown in Figure 8 determines that the slideshow's position within a multimedia presentation is the position x = 100 pixel and y = 50 pixel in relation to the position of its parent node.

With basic and complex composition operators one can build multimedia composition functionality that is equivalent to the composition functionality of advanced multimedia document models like Madeus (Jourdan et al., 1998) and ZYX (Boll & Klas, 2001). Though complex composition operators can have an arbitrary number of parameters and can be configured individually each time they are used, the internal structure of complex operators is still static. Once a complex operator is defined, the number of parameters and their type are fixed and cannot be changed. Using a complex composition operator can be regarded as filling in fixed composition templates with suitable media elements. Personalization can only take place in selecting those media elements that fit the user profile information at best. For the dynamic creation of *personalized* multimedia content even more sophisticated composition functionality is needed, that allows the composition operators to change the structure of the generated multimedia content at runtime. To realize such sophisticated composition functionality, additional composition logic needs to be included into the composition operators, which cannot be expressed anymore even by the mentioned advanced document models we find in the field.

Sophisticated Composition Functionality

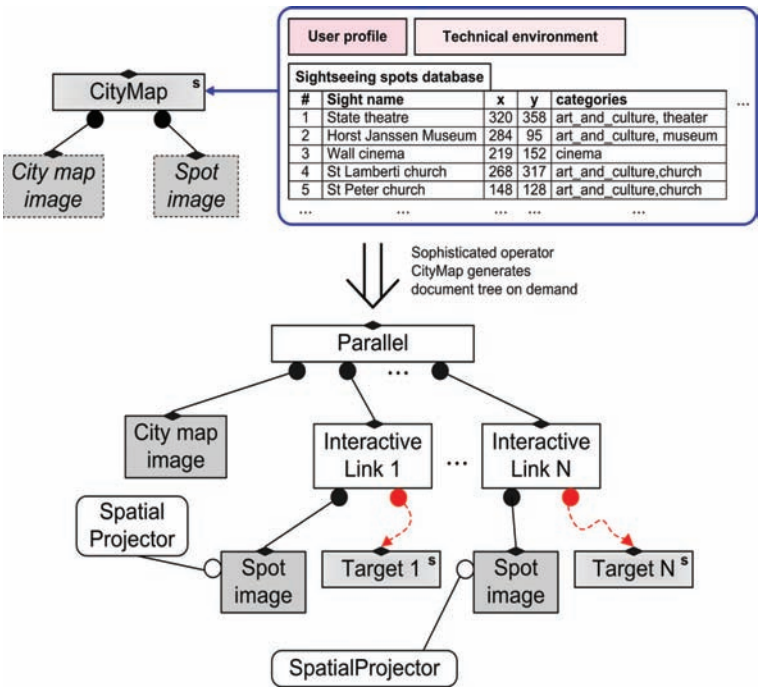
With basic and complex composition functionality, we already provide the dynamic composition of prestructured multimedia content by parameterized multimedia composition templates. However, such templates are only flexible concerning the selection of the concrete composition parameters. To achieve an even more flexible dynamic content composition, the framework provides sophisticated composition operators, which allow determining the document structure and layout during creation time by additional composition logic. Multimedia composition templates defined by using such sophisticated composition operators are no longer limited to creating prestructured multimedia content only, but determine the document structure and layout of the multimedia content on-the-fly and, depending on the user profile information, the characteristics of the used end device, and any other additional information. The latter can be, for example, a database containing sightseeing information. Such sophisticated composition operators exploit the basic and complex composition operators the MM4U framework offers but allow more flexible, possibly application-specific multimedia composition and personalization functionality with their additional composition logic. This compo-

sition logic can be realized by using document structures, templates, constraints and rules, or by plain programming. Independent of how the sophisticated multimedia content composition functionality is actually realized, the result of this composition process is always a multimedia document tree that consists of basic and complex operators, projectors, as well as media elements. In our graphical notation, sophisticated composition operators are represented in the same way as complex operators, but are labeled with a small "s" symbol in the upper right corner.

Figure 9 shows an example of a parameterized sophisticated composition operator, the *CityMap*. This operator provides the generation of a multimedia presentation containing a city map image together with a set of available sightseeing spots on it. The parameters of this sophisticated operator are the city map image of arbitrary size and a spot image used for presenting the sights on the map. Furthermore, the CityMap operator reads out the positions of the sights on a reference map (indicated by the table on the right) and automatically recalculates the positions in dependence of the size of the actual city map image. Which spots are selected and actually presented on the city map depends on the user profile, in particular the types of sights he or she is interested in, and the categories a sight belongs to. In addition, the size of the city map image is selected to best fit the display of the end device. The CityMap operator is used within our personalized city guide prototype presented in the section on Sightseeing 4U and serves there for Desktop PCs as well as mobile devices.

The multimedia document tree generated by the CityMap operator is shown in the bottom part of Figure 9. Its root element constitutes the Parallel operator. Attached to it are the image of the city map and a set of InteractiveLink operators. Each InteractiveLink represents a spot on the city map, instantiated by the spot image. The

Figure 9. Insight into the sophisiticated composition operator CityMap



#	Sight name	x	y	categories
1	State theatre	320	358	art_and_culture, theater
2	Horst Janssen Museum	284	95	art_and_culture, museum
3	Wall cinema	219	152	cinema
4	St Lamberti church	268	317	art_and_culture,church
5	St Peter church	148	128	art_and_culture,church

user can click on the spots to receive multimedia presentations with further information about the sights. The positions of the spot images on the city map are determined by the SpatialProjectors. The personalized multimedia presentations about the sights are represented by the sophisticated operators Target 1 to Target N.

The CityMap operator is one example of extending the personalization functionality of the MM4U framework by a sophisticated application-specific multimedia composition operator, here in the area of (mobile) tourism applications. This operator, for example, is developed by programming the required dynamic multimedia composition functionality. However, the realization of the internal composition logic of sophisticated operators is independent of the used technology and programming language. The same composition logic could also be realized by using a different technology, for example, a constraint-based approach. Though the actual realization of the personalized multimedia composition functionality would be different, the multimedia document tree generated by this rule-based sophisticated operator would be the same as depicted in Figure 9.

Sophisticated composition operators allow embracing the most different solutions for realizing personalized multimedia composition functionality. This can be plain programming as in the example of the CityMap operator, document structures and templates that are dynamically selected according to the user profile information and filled in with media elements relevant to the user, or systems describing the multimedia content generation by constraints and rules.

The core MM4U framework might not offer all kinds of personalized multimedia composition functionality one might require, since the personalization functionality always depends on the actual application to be developed and thus can be very specific. Instead, the framework provides the basis to develop sophisticated personalized multimedia composition operators, such that every application can integrate its own personalization functionality into the framework. So, every sophisticated composition operator can be seen as a "small application" itself that can conduct a particular multimedia personalization functionality. This small application can be reused within others and thus extends the functionality of the framework. The Multimedia Composition component allows a seamless plug-in of arbitrary sophisticated composition operators into the MM4U framework. This enables the most complex personalized multimedia composition task to be "just" plugged into the system and to be used by a concrete personalized multimedia application.

With the sophisticated composition operators, the MM4U framework provides its most powerful and flexible functionality to generate arbitrary personalized multimedia content. However, this multimedia content is still represented in an internal document model and has to be transformed into a presentation format that can be rendered and displayed by multimedia players on the end devices.

From Multimedia Composition to Presentation

In the last step of the personalization process, the personalized multimedia content represented in our internal document model is transformed by the Presentation Format Generators component into one of the supported standardized multimedia presentation formats, which can be rendered and displayed on the client device. The output format of the multimedia presentation is selected according to the user's preferences and the capabilities of the end device, that is, the available multimedia players and the multimedia presentation formats they support.

The Presentation Format Generators adapt the characteristics and facilities of the internal document model provided by the Multimedia Composition layer in regard of the used time model, spatial layout, and interaction possibilities

to the particular characteristics and syntax of the concrete presentation format. For example, the spatial layout of our internal document model is realized by a hierarchical model that supports the positioning of media elements in relation to other media elements. This relative positioning is supported by most of today's presentation formats, for example, SMIL, SVG, and XMT-Omega. However, there exist multimedia presentation formats that do not support such a hierarchical model and only allow an absolute positioning of visual media elements in regard to the presentation's origin as, for example, the Basic Language Profile of SMIL, 3GPP SMIL, and Macromedia's Flash. In this case, the Presentation Format Generators component transforms the hierarchically organized spatial layout of the internal document model to a spatial layout of absolute positioning. How the transformation of the spatial model is actually performed and how the temporal model and interaction possibilities of the internal document model are transformed into the characteristics and syntax of the concrete presentation formats is intentionally omitted in this book chapter due to its focus on the composition and assembly of the personalized multimedia content and is described in Scherp and Boll (2005).

IMPACT OF PERSONALIZATION TO THE DEVELOPMENT OF MULTIMEDIA APPLICATIONS

The multimedia personalization framework MM4U presented so far provides support to develop sophisticated personalized multimedia applications. Involved parties in the development of such applications are typically a heterogeneous team of developers from different fields including media designers, computer scientists, and domain experts. In this section, we describe what challenges *personalization* brings to the development of personalized multimedia applications and how and where the MM4U framework can support the developer team to accomplish their job.

In the next subsection, the general software engineering issues in regard to personalization are discussed. We describe how personalization affects the single members of the heterogeneous developer team and how the MM4U framework supports the development of personalized multimedia applications. The challenges that arise with creating personalized multimedia content by the domain experts using an authoring tool are presented in the following subsection. We also introduce how the MM4U framework can be used to develop a domain-specific authoring tool in the field of e-learning content, which aims to hide the technical details of content authoring from the authors and lets them concentrate on the actual creation of the personalized multimedia content.

Influence of Personalization to Multimedia Software Engineering

We observe that software engineering support for multimedia applications such as proper process models and development methodologies are not likely to be found in this area. Furthermore, the existing process models and development methodologies for multimedia applications as for example Rout and Sherwood (1999) and Engels et al. (2003) do not support personalization aspects. However, personalization requirements complicate the software development process even more and increase the development costs, since every individual alternative and variant has to be anticipated, considered, and actually implemented. Therefore, there is a high demand in supporting the development process of such applications. In the following paragraphs, we first introduce how personalization affects the software development process with respect to the multimedia content creation process in general. Then we identify what support the developers of

personalized multimedia applications need and consider where the MM4U framework supports the development process.

Since the term *personalization* profoundly depends on the application's context, its meaning has ever to be reconsidered when developing a personalized application for a new domain. Rossi et al. (2001) claim that personalization should be considered directly from the beginning when a project is conceived. Therefore, the first activity when developing a personalized multimedia application is to determine the personalization requirements, that is, which aspects of personalization should be supported by the actual application. For example, in the case of an e-learning application the personalization aspects consider the automatic adaptation to the different learning styles of the students and their prior knowledge about the topic. In addition, different degrees of difficulty should be supported by a personalized e-learning application. In the case of a personalized mobile tourism application, however, the user's location and his or her surroundings would be of interest for personalization instead. These personalization aspects must be kept in mind during every activity throughout the whole development process. The decision regarding which personalization aspects are to be supported has to be incorporated in the analysis and design of the personalized application and will hopefully entail a flexible and extendible software design. However, this increases the overall complexity of the application to be developed and automatically leads to a higher development effort including longer development duration and higher costs. Therefore, a good requirement analysis is crucial when developing personalized applications lest one dissipates one's energies in bad software design with respect to the personalization aspects.

When transferring the requirements for developing personalized software to the specific requirements of personalized multimedia applications one can say that it affects all members of the developer team: the domain expert, the media designers, and the computer scientists, and putting higher requirements to them.

The domain expert normally contributes to the development of multimedia applications by providing input to draw storyboards of the specific application's domain. These storyboards are normally drawn by media designers and are the most important means to communicate the later application's functionality within the developer team. When personalization comes into account, it is difficult to draw such storyboards, because of the many possible alternatives and different paths in the application that are implicated with personalization. Consequently, the storyboards change in regard to, for example, the individual user profiles and the end devices that are used. When drawing storyboards for a *personalized* multimedia application, those points in the storyboard have to be identified and visualized where personalization is required and needed. Storyboards have to be drawn for every typical personalization scenario concerning the concrete application. This drawing task should be supported by interactive graphical tools to create "personalized" storyboards and to identify reusable parts and modules of the content.

It is the task of the media designer in the development of multimedia applications to plan, acquire, and create media elements. With personalization, media designers have to think additionally about the usage of media elements for personalization purposes, that is, the media elements have to be created and prepared for different contexts. When acquiring media elements, the media designers must consider for which user context the media elements are created and what aspects of personalization are to be supported, for example, different styles, colours, and spatial dimensions. Possibly a set of quite similar media assets have to be developed, that only differ in certain aspects. For example, an image or video has to be transformed for different end device resolutions, colour depth, and network connections. Since personalization means to (re)assemble

existing media elements into a new multimedia presentation, the media designers will also have to identify reusable media elements. This means that additionally the storyboards must already capture the personalization aspects. Not only the content but also the layout of the multimedia application can change depending on the user context. So, the media designers have to create different visual layouts for the same application to serve the needs of different user groups. For example, an e-learning system for children would generate colourful multimedia presentations with many auditory elements and a comic-like virtual assistant, whereas the system would present the same content in a much more factual style for adults. This short discussion shows that personalization already affects the storyboarding and media acquisition. Creating media elements for personalized multimedia applications requires a better and elaborate planning of the multimedia production. Therefore, a good media production strategy is crucial, due to the high costs involved with the media production process. Consequently, the domain experts and the media designers need to be supported by appropriate tools for planning, acquiring, and editing media elements for personalized multimedia applications.

The computer scientists actually have to develop the multimedia personalization functionality of the concrete application. What this personalization functionality is depends heavily on the concrete application domain and is communicated with the domain experts and media designers by using personalized storyboards. With personalization, the design of the application has to be more flexible and more abstract to meet the requirements of changing user profile information and different end device characteristics. This is where the MM4U framework comes into play. It provides the computer scientists the general architecture of the personalized multimedia application and supports them in designing and implementing the concrete multimedia personalization functionality. When using the MM4U framework, the computer scientists must know how to use and to extend it. The framework provides the basis for developing both basic and sophisticated multimedia personalization functionality, as for example the Slideshow or the CityMap operator presented in the section on content. To assist the computer scientists methodically we are currently working on guidelines and checklists of how to develop the personalized multimedia composition operators and how to apply them. Consequently, the development of personalized multimedia applications by using the MM4U framework basically means to the computer scientists the design, development, and deployment of multimedia composition operators for generating personalized content. The concept of the multimedia personalization operators as introduced in the content section, that every concrete personalized multimedia application is itself a new composition operator increases reusage of existing personalization functionality. Furthermore, the interface design of the sophisticated operators makes it possible to embrace existing approaches that are able to generate multimedia document trees, for example, so it can be generated with the basic and complex composition functionality of the MM4U framework.

Influence of Personalization to Multimedia Content Authoring

Authoring of multimedia content is the process in which the multimedia presentations are actually created. This creation process is typically supported by graphical authoring tools, for example, Macromedia's Authorware and Director (Macromedia, 2004), Toolbook (Click2learn, 2001-2002), (Arndt, 1999), and (Gaggi & Celentano, 2002). For creating the multimedia content, the authoring tools follow different design philosophies and metaphors, respectively. These metaphors can be roughly categorized into script-based, card/page-based, icon-based, timeline-based, and object-based authoring (Rabin & Burns, 1996).

All these different metaphors have the same goal, to support authors in creating their content. Even though based on these metaphors a set of valuable authoring tools has been developed, these metaphors do not necessarily provide a suitable means for authoring personalized content.

From the context of our research project Cardio-OP we derived early experiences with personalized content authoring for domain experts in the field of cardiac surgery (Klas et al., 1999; Greiner & Rose, 1998; Boll et al., 2001). One of the tools developed by a project partner, the Cardio-OP Authoring Wizard, is a page-based easy-to-use multimedia authoring environment, enabling medical experts to compose a multimedia book on operative techniques in the domain of cardiac surgery for three different target groups, medical doctors, nurses, and students. The Authoring Wizard guides the author through the particular authoring steps and offers dialogues specifically tailored to the needs of each step. Coupled tightly with an underlying media server, the authoring wizard allows use of every precious piece of media data available at the media server in all of the instructional applications at different educational levels. This promotes reuse of expensively produced content in a variety of different contexts.

Personalization of the e-learning content is required here, since the three target groups have different views and knowledge about the domain of cardiac surgery. Therefore, the target groups require different information from such a multimedia book, presented on an adequate level of difficulty for each group.

However, the experiences we gained from deploying this tool show that it is hard to provide the domain authors with an adequate intuitive user interface for the creation of personalized multimedia e-learning content for three educational levels. It was a specific challenge for the computer scientists involved in the project to provide both media creation tools and multimedia authoring wizard that allow the domain experts to insert knowledge into the system, while at the same time hiding the technical details from them as much as possible.

On the basis of the MM4U framework, we are currently developing a "smart authoring tool" aimed for domain experts to create personalized multimedia e-learning content. The tool we are developing works at the what-you-see-is-what-you-get (WYSIWYG) level and can be seen as a specialized application employing the framework to create personalized content. The content source from which this personalized e-learning content is created constitutes the LEBONED repositories. Within the LEBONED project (Oldenettel & Malachinski, 2003) digital libraries are integrated into learning management systems. Using the content managed by the LEBONED system for new e-learning units, a multimedia authoring support is needed for assembling existing e-learning modules into new, possibly more complex, units. In the e-learning context, the background of the learners is very relevant for the content that meets the users learning demands — that means a personalized multimedia content can meet the user's background knowledge and interest much better than a one-size-fits-all e-learning unit. The creation of an e-learning unit on the other side cannot be supported by a mere automatic process. Rather the domain experts would like to control the assembly of the content because they are responsible for the content conveyed. The smart authoring tool guides the domain experts through the composition process and supports them in creating presentations that still provide flexibility to the targeted user context. In the e-learning context we can expect domain experts such as lecturers that want to create a new e-learning unit but do not want to be bothered with the technical details of (multimedia) authoring.

We use the MM4U framework to build the multimedia composition and personalization functionality of this smart authoring tool. For this, the Multimedia Composition component supports the creation and processing of arbitrary

document structures and templates. The authoring tool exploits this functionality for composition to achieve a document structure that is suitable just for that content domain and the targeted audience. The Media Data Accessor supports the authoring tool in those parts in which it lets the author choose from only those media elements that are suitable for the intended user contexts and that can be adapted to the user's infrastructure. Using the Presentation Format Generators, the authoring tool finally generates the presentations for the different end devices of the targeted users. Thus the authoring process is guided and specialized with regard to selecting and composing personalized multimedia content. For the development of this authoring tool, the framework fulfils the same function in the process of creating personalized multimedia content in a multimedia application as described in the previous section on the framework. However, the creation of personalized content is not achieved at once but step by step during the authoring process.

IMPLEMENTATION AND PROTOTYPICAL APPLICATIONS

The framework, its components, classes and interfaces, are specified using the Unified Modeling Language (UML) and has been implemented in Java. The development process for the framework is carried out as an iterative software development with stepwise refinement and enhancement of the framework's components. The redesign phases are triggered by the actual experience of implementing the framework but also by employing the framework in several application scenarios. In addition, we are planning to provide a beta version of the MM4U framework to other developers for testing the framework and to develop their own personalized multimedia applications with MM4U.

Currently, we are implementing several application scenarios to prove the applicability of MM4U in different application domains. These prototypes are the first stress test for the framework. At the same time the development of the sample applications gives us an important feedback about the comprehensiveness and the applicability of the framework. In the following sections, two of our prototypes that are based on the MM4U framework are introduced: In the Sightseeing4U subsection, a prototype of a personalized city guide is presented, and in the Sports4U subsection a prototype of a personalized multimedia sports news ticker is described.

Sightseeing4U: A Generic Personalized City Guide

Our first prototype using the MM4U framework is Sightseeing4U, a generic personalized city guide application (Scherp & Boll, 2004a, 2004b; Boll et al., 2004). It is applicable to develop personalized tourist guides for arbitrary cities, both for desktop PCs and mobile devices such as PDAs (Personal Digital Assistants). The generic Sightseeing4U application uses the MM4U framework and its modules as depicted in Figure 3. The concrete demonstrator we developed for our hometown Oldenburg in Northern Germany considers the pedestrian zone and comprises video and image material of about 50 sights. The demonstrator is developed for desktop PCs as well as PDAs (Scherp & Boll, 2004a). It supports personalization with respect to the user's interests, for example, churches, museums, and theatres, and preferences such as the favorite language. Depending on the specific sightseeing interests, the proper sights are automatically selected for the user. This is realized by category matching of the user's interests with the meta data associated to the sights. Figure 10 and Figure 11 show some screenshots of our city guide application in different output formats and on different end devices. The presentation in Figure 10 is targeted at a user interested in culture, whereas the presentation in Figure 11 is generated for a user who is hungry and searches for a good

Figure 10. Screenshots of the city guide application for a user interested in culture (presentation generated in SMIL 2.0 and SMIL 2.0 BLP format, respectively)

(a) RealOne Player (RealNetworks, 2003) on a Desktop PC

(b) PocketSMIL Player (INRIA, 2003) on a PDA

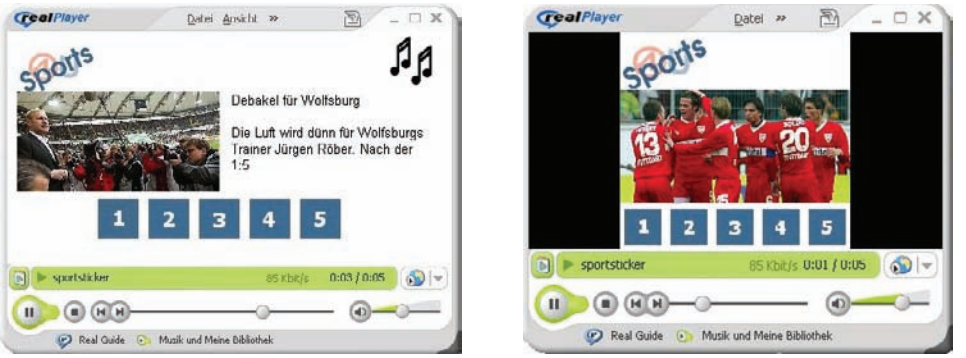
Figure 11. Screenshots of the Sightseeing4U prototype for a user searching for a good restaurant (output generated in SVG 1.2 and Mobile SVG format, respectively)

(a) Adobe SVG Plug-In (Adobe Systems, 2001) on a Tablet PC

(b) Pocket eSVG viewer (EXOR, 2001-2004) on a PDA

restaurant in Oldenburg. The different interests of the users result in different spots that are presented on the map of Oldenburg. When clicking on a certain spot the user receives a multimedia presentation with further information about the sight (see the little boxes where the arrows point). Thereby, the media elements for the multimedia presentation are automatically selected to fit the

Figure 12. Screenshots of the personalized sports newsticker Sport4U



end devices' characteristics best. For example, a user sitting at a desktop PC receives a high-quality video about the palace of Oldenburg as depicted in Figure 10a, while a mobile user gets a smaller video of less quality in Figure 10b. In the same way, the user searching for a good restaurant in Oldenburg receives either a high-quality video when using a Tablet PC as depicted in Figure 11a, or a smaller one that meets the limitations of the mobile device as shown in Figure 11b. If there is no video of a particular sight available at all, the personalized tourist guide automatically selects images instead and generates a slideshow for the user.

Sports4U: A Personalized Multimedia Sports News Ticker

A second prototype that uses our MM4U framework is the personalized multimedia sports news ticker called Sports4U. The Sports4U application exploits the MediÆther multimedia event space as introduced in (Boll & Westermann, 2003). The MediÆther is based on a decentralized peer-to-peer infrastructure and allows one to publish, to find, and to be notified about any kind of multimedia events of interest. In the case of Sports4U, the event space forms the media data basis of sports-related multimedia news events. A multimedia sports news event comprises data of different media types like describing text, a title, one or more images, an audio record, or a video clip. The personalized sports ticker application combines the multimedia data of the selected events, the available meta data, and additional information, for example, from a soccer player database. The application uses a sophisticated composition operator that automatically arranges these multimedia sports news to a coherent presentation. It regards possible constraints like running time limit and particular characteristics of the end device, like the limited display size of a mobile device. The result is a sports news presentation that can be, for example, viewed with an SMIL player over the Web as shown in Figure 12. With a suitable Media Data Connector the MediÆther is connected to the MM4U framework. This connector not only allows querying for media elements like the URIMediaConnector but also provides the notification of incoming multimedia events to the actual personalized application. Depending on the user context, the Sports4U prototype receives the sports news from the pool of sports events in the MediÆther that match the users profile. The Sports4U application alleviates the user from the time-consuming task of searching for sports news he or she might be interested in.

CONCLUSION

In this chapter, we presented an approach for supporting the creation of personalized multimedia content. We motivated the need of technology to handle the flood of multimedia information that allows for a much targeted, individual management and access to multimedia content. To give a better understanding of the content creation process we introduced the general approaches in multimedia data modeling and multimedia authoring as we find it today. We presented how the need for personalization of multimedia content heavily affects the multimedia content creation process and can only result in a dynamic, (semi)automatic support for the personalized assembly of multimedia content. We looked into existing related approaches ranging from personalization in the text-centric Web context over single media personalization to the personalization of multimedia content. Especially for complex personalization tasks we observe that an (additional) programming is needed and propose a software engineering support with our Multimedia for you Framework (MM4U).

We presented the MM4U framework concept in general and, in more detail, the single layers of the MM4U framework: access to user profile information, personalized media selection by meta data, composition of complex multimedia presentations, and generation of different output formats for different end devices. As a central part of the framework, we developed multimedia composition operators which create multimedia content in an internal model and representation for multimedia presentations, integrating the composition capabilities of advanced multimedia composition models. Based on this representation, the framework provides so-called generators to dynamically create different context-aware multimedia presentations in formats such as SMIL and SVG. The usage of the framework and its advantages has been presented in the context of multimedia application developers but also in the specific case of using the framework's specific features for the development of a high-level authoring tool for domain experts.

With the framework developed, we achieved our goals concerning the development of a domain independent framework that supports the creation of personalized multimedia content independent of the final presentation format. Its design allows to "just" use the functionality it provides, for example, the access to media data, associated meta data, and user profile information, as well as the generation of the personalized multimedia content in standardized presentation formats. Hence, the framework relieves the developers of personalized multimedia applications from common tasks needed for content personalization, that is, personalized content selection, composition functionality, and presentation generation, and lets them concentrate on their application-specific job. However, the framework is also designed to be extensible with regard to application-specific personalization functionality, for example, by an application-specific personalized multimedia composition functionality. With the applications in the field of tourism and sports news we illustrated the usage of the framework in different domains and showed how the framework easily allows one to dynamically create personalized multimedia content for different user contexts and devices.

The framework has been designed not to become yet another framework but to base on and integrate previous and existing research in the field. The design has been based on our long-term experience in advanced multimedia composition models and an extensive study of previous and ongoing related approaches. Its interfaces and extensibility explicitly allow not only to extend the framework's functionality but to embrace existing solutions of other (research) approaches in the field. The dynamically created personalized multimedia content needs semantically rich annotated content in the respective media databases. In turn, the newly created content itself not only provides users with personalized multimedia information but

at the same time forms a new, semantically even richer multimedia content that can be retrieved and reused. The composition operators provide common multimedia composition functionality but also allow the integration of very specific operators. The explicit decision for presentation independence by a comprehensive internal composition model makes the framework both independent of any specific presentation format and prepares it for future formats to come.

Even though a software engineering approach towards dynamic creation of personalized multimedia content may not be the obvious one, we are convinced that our framework fills the gap between dynamic personalization support based on abstract data models, constraints or rules, and application-specific programming of personalized multimedia applications. With the MM4U framework, we are contributing to a new but obvious research challenge in the field of multimedia research, that is, the shift from tools for the manual creation of static multimedia content towards techniques for the dynamic creation of, respectively, context-aware and personalized multimedia content, which is needed in many application fields. Due to its domain independence, MM4U can be used by arbitrary personalized multimedia applications, each application applying a different configuration of the framework. Consequently, for providers of applications the framework approach supports a cheaper and quicker development process and by this contributes to a more efficient personalized multimedia content engineering.

ABSTRACT

Current semantic approaches to multimedia content modeling treat the content's media, the semantic description of the content, and the functionality performed on the content, such as rendering, as separate entities, usually kept on separate servers in separate files or databases and typically under the control of different authorities. This separation of content from its description and functionality hinders the exchange and sharing of content in collaborative multimedia application scenarios. In this chapter, we propose Enhanced Multimedia MetaObjects (Emmos) as a new content modeling formalism that combines multimedia content with its description and functionality. Emmos can be serialized and exchanged in their entirety — covering media, description, and functionality — and are versionable, thereby establishing a suitable foundation for collaborative multimedia applications. We outline a distributed infrastructure for Emmo management and illustrate the benefits and usefulness of Emmos and this infrastructure by means of two practical applications.

INTRODUCTION

Today's multimedia content formats such as HTML (Raggett et al., 1999), SMIL (Ayars et al., 2001), or SVG (Ferraiolo et al., 2003) primarily encode the presentation of content but not the information content conveys. But this *presentation-oriented* modeling only permits the hard-wired presentation of multimedia content exactly in the way specified; for advanced operations like retrieval and reuse, automatic composition, recommendation, and adaptation of content according to user interests, information needs, and technical infrastructure, valuable information about the semantics of content is lacking.

In parallel to research on the Semantic Web (Berners-Lee et al., 2001; Fensel, 2001), one can therefore observe a shift in paradigm towards a *semantic* modeling of multimedia content. The basic media of which multimedia content consists are supplemented with metadata describing these media and their semantic interrelationships. These media and descriptions are processed by stylesheets, search engines, or user agents providing advanced functionality on the content that can exceed mere hard-wired playback.

Current semantic multimedia modeling approaches, however, largely treat the content's basic media, the semantic description, and the functionality offered on the content as separate entities: the basic media of which multimedia content consists are typically stored on web or media servers; the semantic descriptions of these media are usually stored in databases or in dedicated files on web servers using formats like RDF (Lassila & Swick, 1999) or Topic Maps (ISO/IEC JTC 1/SC 34/WG 3, 2000); the functionality on the content is normally realized as servlets or stylesheets running in application servers or as dedicated software running at the clients such as user agents.

This inherent separation of media, semantic description, and functionality in semantic multimedia content modeling, however, hinders the realization of multimedia content sharing as well as collaborative applications which are gaining more and more importance, such as the sharing of MP3 music files (Gnutella, n.d.) or learning materials (Nejdl et al., 2002) or the collaborative authoring and annotation of multimedia patient records (Grimson et al., 2001). The problem is that exchanging content today in such applications simply means exchanging single media files. An analogous exchange of semantically modeled multimedia content would have to include content descriptions and associated functionality, which are only coupled loosely to the media and usually exist on different kinds of servers potentially under control of different authorities, and which are thus not easily moveable.

In this chapter, we give an illustrated introduction to Enhanced Multimedia MetaObjects (Emmo), a semantic multimedia content modeling approach developed with collaborative and content sharing applications in mind. Essentially, an Emmo constitutes a self-contained piece of multimedia content that merges three of the content's aspects into a single object: the *media aspect*, that is, the media which make up the multimedia content, the *semantic aspect* which describes the content, and the *functional aspect* by which an Emmo can offer meaningful operations on the content and its description that can be invoked and shared by applications. Emmos in their entirety — including media, content description, and functionality — can be *serialized* into bundles and are *versionable*: essential characteristics that enable their exchangeability in content sharing applications as well as the distributed construction and modification of Emmos in collaborative scenarios.

Furthermore, this chapter illustrates how we employed Emmos for two concrete collaborative and content sharing applications in the domains of cultural heritage and digital music archives.

The chapter is organized as follows: we begin with an overview of Emmos and show their difference to existing approaches for multimedia content

modeling. We then introduce the conceptual model behind Emmos and outline a distributed Emmo container infrastructure for the storage, exchange, and collaborative construction of Emmos. We then apply Emmos for the representation of multimedia content in two application scenarios. We conclude this paper with a summary and give an outlook to our current and future work.

BACKGROUND

In this section, we provide a basic understanding of the Emmo idea by means of an illustrating example. We show the uniqueness of this idea by relating Emmos to other approaches to multimedia content modeling in the field.

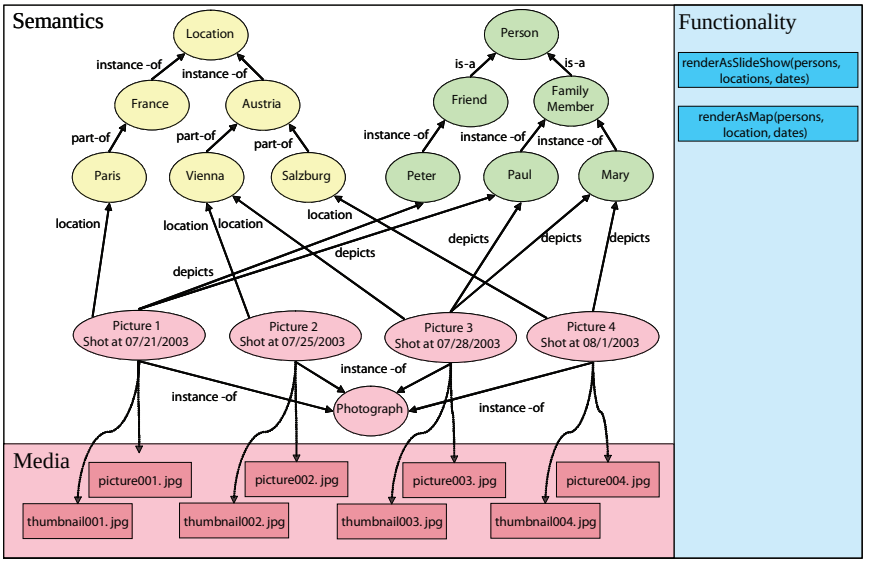
The Emmo Idea

The motivation for the development of the Emmo model is the desire to realize multimedia content sharing and collaborative applications on the basis of semantically modeled content but to avoid the limitations and difficulties of current semantic modeling approaches implied by their isolated treatment of media, semantic description, and content functionality.

Following an abstract vision originally formulated by (Reich et al., 2000), the essential idea behind Emmos is to keep semantic description and functionality tied to the pieces of content to which they belong, thereby creating self-contained units of semantically modeled multimedia content easier to exchange in content sharing and collaborative application scenarios. An Emmo coalesces the basic media of which a piece of multimedia content consists (i.e., the content's *media aspect*), the semantic description of these media (i.e., the content's *semantic aspect*), and functionality on the content (i.e., the content's *functional aspect*) into a single serializeable and versionable object.

Figure 1 depicts a sketch of a simplified Emmo, which models a small multimedia photo album of a holiday trip of an imaginary couple Paul and Mary and their friend Peter. The bottom of the figure illustrates how Emmos address the *media*

Figure 1. Aspects of an Emmo



aspect of multimedia content. An Emmo acts as a container of the basic media of which the content that is represented by the Emmo consists. In our example, the Emmo contains four JPEG images which constitute the different photographs of the album along with corresponding thumbnail images.

Media can be contained either by inclusion, that is, raw media data is directly embedded within an Emmo, or by reference via a URI if embedding raw media data is not feasible because of the size of media data or the media is a live stream.

An Emmo further carries a semantic description of the basic media it contains and the associations between them. This *semantic aspect*, illustrated to the upper left of Figure 1, makes an Emmo a unit of knowledge about the multimedia content it represents.

For content description, Emmos apply an expressive concept graph-like data model similar to RDF and Topic Maps. In this graph model, the description of the content represented by an Emmo is not performed directly on the media that are contained in the Emmo; instead, the model abstracts from physical media making it possible to subsume several media objects which constitute only different physical manifestations of logically one and the same medium under a single media node. This is a convenient way to capture alternative media. In Figure 1, for example, each media node Picture 1 … Picture 4 subsumes not only a photo but also its corresponding thumbnail image.

Apart from media, nodes can also represent abstract concepts. By associating an Emmo's media objects with such concepts, it is possible to create semantically rich descriptions of the multimedia content the Emmo represents. In Figure 1, for instance, it is expressed that the logical media nodes Picture 1 … Picture 4 constitute photos taken in Paris, Vienna, and Salzburg showing Peter and Paul, Paul and Mary, and Mary, respectively. The figure further indicates that nodes can be augmented with primitive attribute values for closer description: the pictures of the photo album are furnished with the dates at which they have been shot.

By associating concepts with each other, it is also possible to express domain knowledge within an Emmo. It is stated in our example that Peter, Paul, and Mary are Persons, that Paul and Mary are family members, that Peter is a friend, that Paris is located in France, and that Vienna and Salzburg are parts of Austria.

The Emmo model does not predefine the concepts, association types, and primitive attributes available for media description; these can be taken from arbitrary, domain-specific ontologies. While they thus constitute a very generic, flexible, and expressive approach to multimedia content model-

Figure 2. Emmo functionality

ing, Emmos are not ready-to-use formalism but require an agreed common ontology before they can be employed in an application.

Finally, Emmos also address the *functional aspect* of content. An Emmo can offer operations that can be invoked by applications in order to work with the content the Emmo represents in a meaningful manner. As shown to the top right of Figure 1, our example Emmo provides two operations supporting two different rendition options for the photo album, which are illustrated by the screenshots of Figure 2. As indicated by the left screenshot, the operation renderAsSlideshow()might know how to — given a set of persons, locations, as well as time periods of interest — render the photo album as a classic slideshow on the basis of the contained pictures and their semantic description by generating an appropriate SMIL presentation. As indicated by the right screenshot, the operation renderAsMap() might also know how to — given the same data — render the photo album as a map with thumbnails pointing to the locations where photographs have been taken by constructing an SVG graph.

One may think of many further uses of operations. For example, operations could also be offered for rights clearance, displaying terms of usage, and so forth.

Emmos have further properties: an Emmo can be *serialized* and shared in its entirety in a distributed content sharing scenario including its contained media, the semantic description of these media, and its operations. In our example, this means that Paul can accord Peter the photo album Emmo as a whole — for instance, via email or a file-sharing peer-to-peer infrastructure — and Peter can do anything with the Emmo that Paul can also do, including invoking its operations.

Emmos also support *versioning.* Every constituent of an Emmo is versionable, an essential prerequisite for applications requiring the distributed and collaborative authoring of multimedia content. This means that Peter, having received the Emmo from Paul, can add his own pictures to the photo album while Paul can still modify his local copy. Thereby, two concurrent versions of the Emmo are created. As the Emmo model is able to distinguish both versions, Paul can merge them into a final one when he receives Peter's changes.

Related Approaches

The fundamental idea underlying the concept of Emmos presented beforehand is that an Emmo constitutes an object unifying three different aspects of multimedia content, namely the media aspect, the semantic aspect, and the functional aspect. In the following, we fortify our claim that this idea is unique.

Interrelating basic media like single images and videos to form multimedia content is the task of multimedia document models. Recently, several standards for multimedia document models have emerged (Boll et al., 2000), such as HTML (Ragett et al., 1999), XHTML+SMIL (Newmann et al., 2002), HyTime (ISO/IEC JTC 1/SC 34/WG 3, 1997), MHEG-5 (ISO/IEC JTC 1/SC 29, 1997), MPEG-4 BIFS and XMT (Pereira & Ebrahimi, 2002), SMIL (Ayars et al., 2001), and SVG (Ferraiolo et al., 2003). Multimedia document models can be regarded as composite media formats that model the presentation of multimedia content by arranging basic media according to temporal, spatial, and interaction relationships. They thus mainly address the media aspect of multimedia content. Compared to Emmos, however, multimedia document models neither interrelate multimedia content according to semantic aspects nor do they allow providing functionality on the content. They rely on external applications like presentation engines for content processing.

As a result of research concerning the Semantic Web, a variety of standards have appeared that can be used to model multimedia content by describing the information it conveys on a semantic level, such as RDF (Lassila & Swick, 1999; Brickley & Guha, 2002), Topic Maps (ISO/IEC JTC 1/SC

34/WG 3, 2000), MPEG-7 (especially MPEG-7's graph tools for the description of content semantics (ISO/IEC JTC 1/SC 29/WG 11, 2001)), and Conceptual Graphs (ISO/JTC1/SC 32/WG 2, 2001). These standards clearly cover the semantic aspect of multimedia content. As they also offer means to address media within a description, they undoubtedly refer to the media aspect of multimedia content as well. Compared to Emmos, however, these approaches do not provide functionality on multimedia content. They rely on external software like database and knowledge base technology, search engines, user agents, and so forth, for the processing of content descriptions. Furthermore, media descriptions and the media described are separate entities — potentially scattered around different places on the Internet, created and maintained by different and unrelated authorities not necessarily aware of each other and not necessarily synchronized — whereas Emmos combine media and their semantic relationships into a single indivisible unit.

There exist several approaches that represent multimedia content by means of objects. Enterprise Media Beans (EMBs) (Baumeister, 2002) extend the Enterprise Java Beans (EJBs) architecture (Matena & Hapner, 1998) with predefined entity beans for the representation of basic media within enterprise applications. These come with rudimental access functionality but can be extended with arbitrary functionality using the inheritance mechanisms available to all EJBs. Though addressing the media and functional aspects of content, EMBs in comparison to Emmo are mainly concerned with single media content and not with multimedia content. Furthermore, EMBs do not offer any dedicated support for the semantic aspect of content.

Adlets (Chang & Znati, 2001) are objects that represent individual (not necessarily multimedia) documents. Adlets support a fixed set of predefined functionality which enables them to advertise themselves to other Adlets. They are thus content representations that address the media as well as the functional aspect. Different from Emmos, however, the functionality supported by Adlets is limited to advertisement and there is no explicit modeling of the semantic aspect.

Tele-Action Objects (TAOs) (Chang et al., 1995) are object representations of multimedia content that encapsulate the basic media of which the content consists and interlink them with associations. Though TAOs thus address the media aspect of multimedia content in a way similar to Emmos, they do not adequately cover the semantic aspect of multimedia content: only a fixed set of five association types is supported mainly concerned with temporal and spatial relationships for presentation purposes. TAOs can further be augmented with functionality. Such functionality is, in contrast to the functionality of Emmos, automatically invoked as the result of system events and not explicitly invoked by applications.

Distributed Active Relationships (Daniel et al., 1998) define an object model based on the Warwick Framework (Lagoze et al., 1996). In the model, Digital Objects (DOs), which are interlinked with each other by semantic relationships, act as containers of metadata describing multimedia content. DOs thus do not address the media aspect of multimedia content but focus on the semantic aspect. The links between containers can be supplemented with arbitrary functionality. As a consequence, DOs take account of the functional aspect as well. Different from Emmos, however, the functionality is not explicitly invoked by applications but implicitly whenever an application traverses a link between two DOs.

ENHANCED MULTIMEDIA META OBJECTS

Having motivated and illustrated the basic idea behind them, this section semiformally introduces the conceptual model underlying Emmos using UML class diagrams. A formal definition of this

Figure 3. Management of basic media in an Emmo

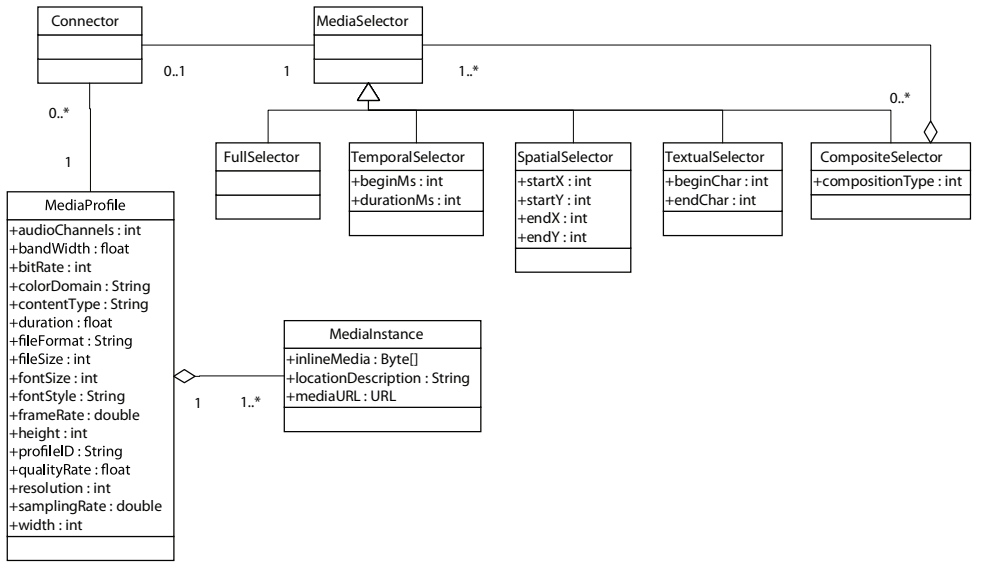


Figure 4. Semantic aspect of Emmos

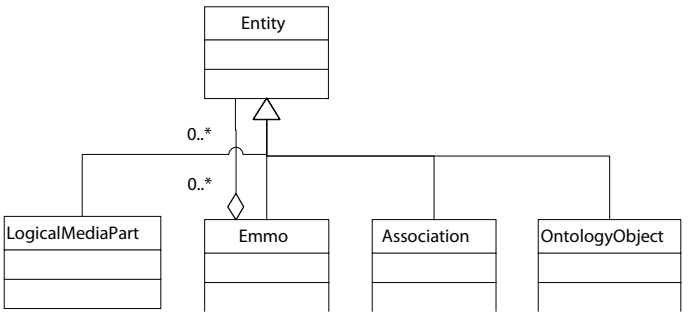

model can be found in (Schellner et al., 2003). The discussion is oriented along the three aspects of multimedia content encompassed by Emmos: the media aspect, the semantic aspect, and the functional aspect.

Media Aspect

Addressing the media aspect of multimedia content, an Emmo encapsulates the basic media of which the content it represents is composed. Figure 3 presents the excerpt of the conceptual model which is responsible for this.

Closely following the MPEG-7 standard and its multimedia description tools (ISO/IEC JTC 1/SC 29/WG 11, 2001), basic media are modeled by *media profiles* (represented by the class MediaProfile in Figure 3) along with associated media instances (represented by the class MediaInstance). Media profiles hold low-level metadata describing physical characteristics of the media such as the storage format, file size, and so forth.; the media data itself is represented by *media instances*, each of which may directly embed the data in form of a byte array or, if that is not possible or feasible, address its storage lo-

cation by means of a URI. Moreover, if a digital representation is not available, a textual location description can be specified, for example the location of analog tapes in some tape archive. Figure 3 further shows that a media profile can have more than one media instances. In this way, an Emmo can be provided with information about alternative storage locations of media.

Basic media represented by media profiles and media instances are attached to an Emmo by means of a *connector* (see class Connector in Figure 3). A connector does not just address a basic medium via a media profile; it may also refer to a *media selector* (see base class MediaSelector) to address only a part of the medium. As indicated by the various subclasses of MediaSelector, it is possible to select media parts according to simple textual, spatial, temporal and textual criteria, as well as an arbitrary combination of these criteria (see class CompositeSelector). It is thus possible to address the upper right part of a scene in a digital video starting from second 10 and lasting until second 30 within an Emmo without having to extract that scene and put it into a separate media file using a video editing tool.

Semantic Aspect

Out of the basic media which it contains, an Emmo forges a piece of semantically modeled multimedia content by describing these media and their semantic interrelationships. The class diagram of Figure 4 gives an overview over the part of the Emmo model that provides these semantic descriptions. As one can see, the basic building blocks of the semantic descriptions, the so-called *entities*, are subsumed under the common base class Entity. The Emmo model distinguishes four kinds of entities: namely, *logical media parts*, *associations*, *ontology objects*, and *Emmos* themselves, represented by assigned subclasses. These four kinds of entities have a common nature but each extends the abstract notion of an entity with additional characteristic features.

Figure 5 depicts the characteristics that are common to all kinds of entities. Each entity is globally and uniquely identified by its OID, realized by means of a universal unique identifier (UUID) (Leach, 1998) which can be easily created even in distributed scenarios. To enhance human readability and usability, each entity is further augmented with additional attributes like a name and a textual description. Moreover, each entity holds information about its creator and its creation and modification date.

Figure 5 further expresses that entities may receive an arbitrary number of *types*. A type is a concept taken from an ontology and represented by an ontology object in the model. Types thus constitute entities themselves. By attaching types, an entity gets meaning and is classified in an application-dependent ontology. As mentioned before, the Emmo model does not come with a predefined set of ontology objects but instead relies on applications to agree on common ontology before the Emmo model can be used.

In the example of Figure 6, the entity Picture 3 of kind logical media part (depicted as a rectangle), which represents the third picture of our example photo album of the holiday trip introduced in the previous section, is an instantiation of the concepts "photograph" and "digital image", represented by the ontology objects photograph and digital image (each pictured by an octagon), respectively. The type relationships are indicated by dashed arrows.

For further description, the Emmo model also allows attaching arbitrary *attribute values* to entities (expressed by the class of the same name in the class diagram of Figure 5). Attribute values are simple attribute-value pairs, with the attributes being a concept of an application-dependent ontology represented by an ontology object entity, and the value being an arbitrary object suiting the type of the value. The rationale behind representing attributes by concepts of an ontology and not just by mere string identifiers is that this allows expressing constraints on the usage of attributes

Figure 5. Entity details

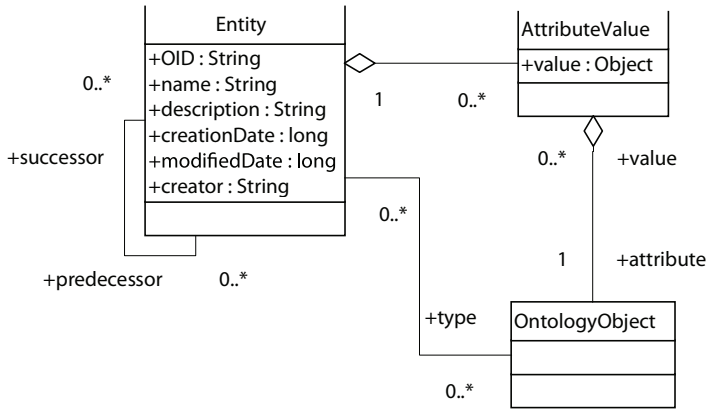

Figure 6. Entity with its types

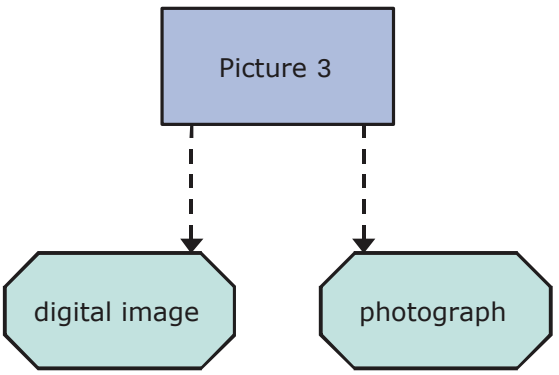

within the ontology; for example, to which entity types attributes are applicable.

Figure 7 gives an example of attribute values. In the figure, it is stated that the third picture of the photo album was taken July 28, 2003, by attaching an attribute value "date=07/28/2003" to the entity Picture 3 representing that picture. The attribute "date" is modeled by the ontology object date and the value "07/28/2003" is captured by an object of a suitable date class (represented using the UML object notation).

As an essential prerequisite for the realization of distributed, collaborative multimedia applications in which multimedia content is simultaneously authored and annotated by different persons at different locations, the Emmo model provides intrinsic support for versioning. The class diagram of Figure 5 states that every entity is versionable and can have an arbitrary number of predecessor and successor versions, all of which have to be entities of the same kind as the original entity. Treating an entity's versions as entities on their own has several benefits: on the one hand, entities constituting versions of other entities have their own globally unique OID. Hence, different versions concurrently derived from one and the same entity at different sites can easily be distinguished without synchronization effort. On the other hand, different versions of an entity can be interrelated just like any other entities allowing one to establish comparative relationships between entity versions.

Figure 7. Entiy with an attribute value

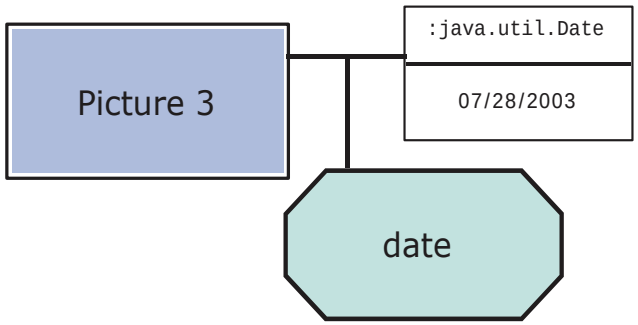

Figure 8. Versioning of an entity

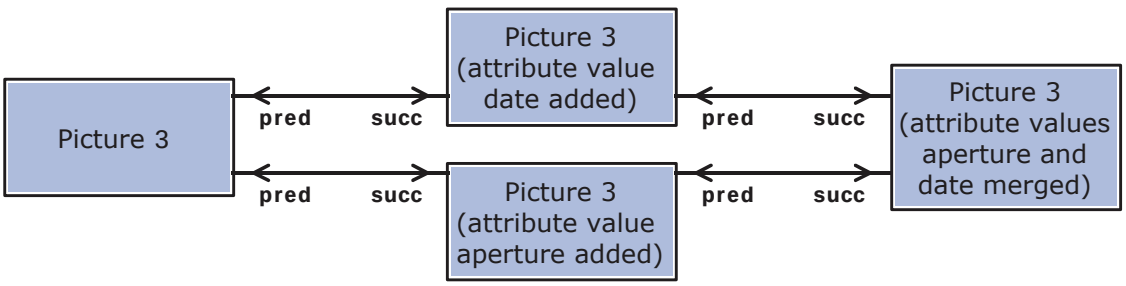

Figure 8 exemplifies a possible versioning of our example entity Picture 3. The original version of this logical part is depicted to the left of the figure. As expressed by the special arrows indicating the predecessor (pred) and the successor (succ) relationship between different versions of the same entity, two different successor versions of this original version were created, possibly by two different people at two different locations. One version augments the logical media part with a date attribute value to denote the creation date of the picture whereas the other provides an attribute value describing the aperture with which the picture was taken. Finally, as shown by the logical media part at the right side of the figure, these two versions were merged again into a fourth that now holds both attribute values.

Having explained the common characteristics shared by all entities, we are now able to introduce the peculiarities of the four concrete kinds of entities: logical media parts, ontology objects, associations, and Emmos.

Logical Media Parts

Logical media parts are entities that form the bridge between the semantic aspect and the media aspect of an Emmo. A logical media part represents a basic medium of which multimedia content consists on a logical level for semantic description, thereby providing an abstraction from the physical manifestation of the medium. According to the class diagram of Figure 9, logical media parts can refer to an arbitrary number of connectors — which we already know from our description of the media aspect of Emmo — permitting one to logically subsume alternative media profiles and instances representing different

media files in possibly different formats in possibly different storage locations under a common logical media part. The ID of the default profile to use is identified via the attribute masterProfileID. Since logical media parts do not need to have connectors associated with them, it is also possible to refer to media within Emmos which do not have a physical manifestation.

Ontology Objects

Ontology objects are entities that represent concepts of an ontology. We have already described how ontology objects are used to define entity types and to augment entities with attribute values. By relating entities such as logical media parts to ontology objects, they can be given a meaning. As it can be seen from the class diagram of Figure 10, the Emmo model distinguishes two kinds of ontology objects represented by two subclasses of OntologyObject: Concept and ConceptRef. Whereas an instance of Concept serves to represent a concept of an ontology that is fully captured within the Emmo model, ConceptRef allows one to reference concepts of ontologies specified in external ontology languages such as RDF Schema (Brickley & Guha, 2002). The latter is a pragmatic tribute to the fact that we have not developed an ontology language for Emmos yet and therefore rely on external languages for this purpose. References to concepts of external ontologies additionally need a special ID (ob-

Figure 9. Logical media parts

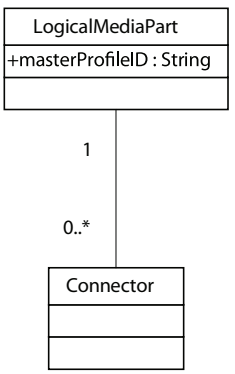

Figure 10. Ontology objects

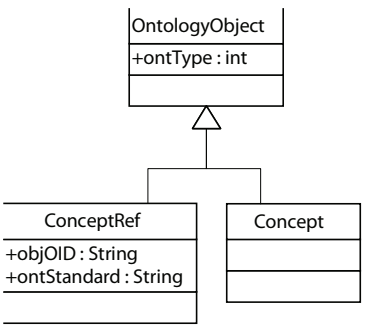

Figure 11. Association

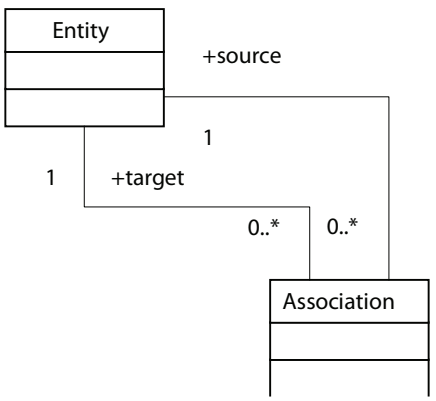


jOID) uniquely identifying the external concept referenced and a label indicating the format of the ontology (ontStandard); for example, "RDF Schema".

Associations

Associations are entities that establish binary directed relationships between entities, allowing the creation of complex and detailed descriptions of the multimedia content represented by the Emmo. As one can see from Figure 11, each association has exactly one *source entity* and one *target entity*. The kind of semantic relationship represented by an association is defined by the association's *type* which is — like the types of other entities — an ontology object representing the concept that captures the type in an ontology. Different from other entities, however, an association is only permitted to have one type as it can express only a single kind of relationship.

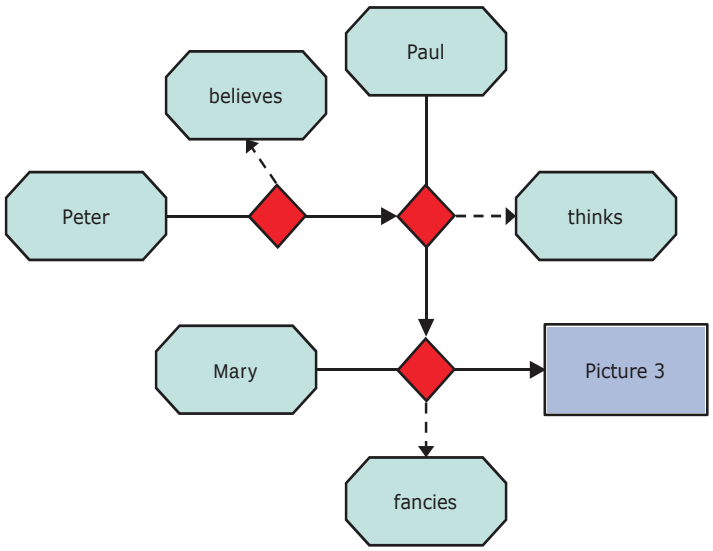
Since associations are first-class entities, they can take part as sources or targets in other associations like any other entities. This feature permits the creation of very complex content descriptions, as it facilitates the reification of statements ("statements about statements") within the Emmo model.

Figure 12 demonstrates how reification can be expressed. In the figure, associations are symbolized by a diamond shape, with solid arrows indicating the source and target of an association and dashed arrows indicating the association type. The example shown in this figure wants to express that "Peter believes that Paul thinks that Mary fancies Picture 3". The statement "Mary fancies Picture 3" is represented at the bottom of the figure by an association of type fancies that connects the ontology object Mary with the logical media part Picture3. Moreover, this association acts as target for another association having the type thinks and the source entity Paul, thereby making a statement about the statement "Mary fancies Picture 3". This reification is then further enhanced by attaching another statement to obtain the desired message.

Emmos

Emmos themselves, finally, constitute the fourth kind of entities. An Emmo is basically a container

Figure 12. Reification



that encapsulates arbitrary entities to form a semantically modeled piece of multimedia content (see the aggregation between the classes Emmo and Entity in the introductory outline of the model in Figure 4). As one and the same entity can be contained in more than one Emmo, it is possible to encapsulate different, context-dependent, and even contradicting, views onto the same content within different Emmo; as Emmo are first-class entities, they can be contained within other Emmos and take part in associations therein, allowing one to build arbitrarily nested Emmo structures for the logical organization of multimedia content. These are important characteristics especially useful for the authoring process, as they facilitate reuse of existing Emmos and the content they represent.

Figure 13 shows an example where a particular Emmo encapsulates another. In the figure, Emmos are graphically shown as ellipses. The example depicts an Emmo modeling a private photo gallery that up to the moment holds only a single photo album (again modeled by an Emmo): namely, the photo album of the journey to Europe we used as a motivating example in the section illustrating the Emmo idea. Via an association, this album is classified as "vacation" within the photo gallery. In the course of time, the photo gallery might become filled with additional Emmos representing further photo albums; for example, one that keeps the photos of a summer vacation in Spain. These Emmos can be related to each other. For example, an association might express that the journey to Europe took place before the summer vacation in Spain.

Functional Aspect

Emmos also address the functional aspect of multimedia content. Emmos may offer *operations* that realize arbitrary content-specific functionality which makes use of the media and descriptions provided with the media and semantic aspects of an Emmo and which can be invoked by applications working with content. The class diagram of Figure 14 shows how this is realized in the model. As expressed in the diagram, an Emmo may aggregate an arbitrary number of operations

Figure 13. Nested Emmo

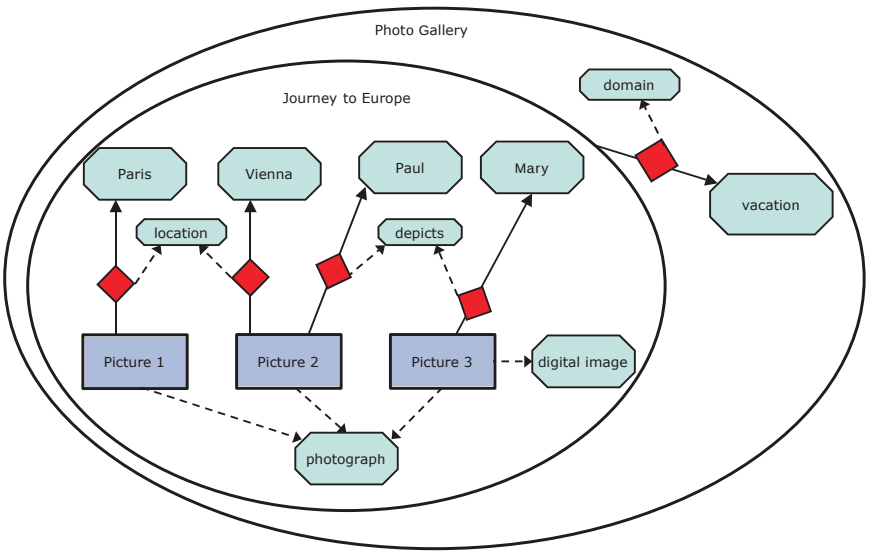


Figure 14. Emmo's functionality

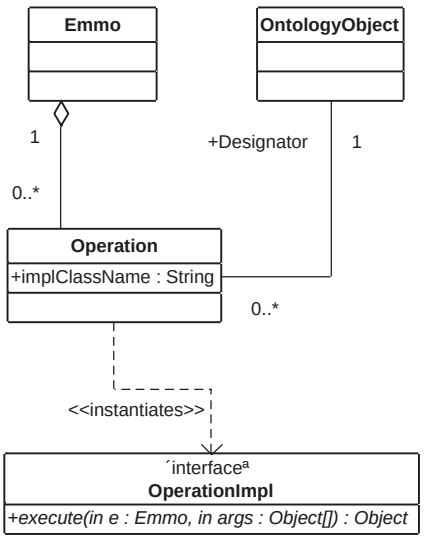

Figure 15. Example of Emmo operations

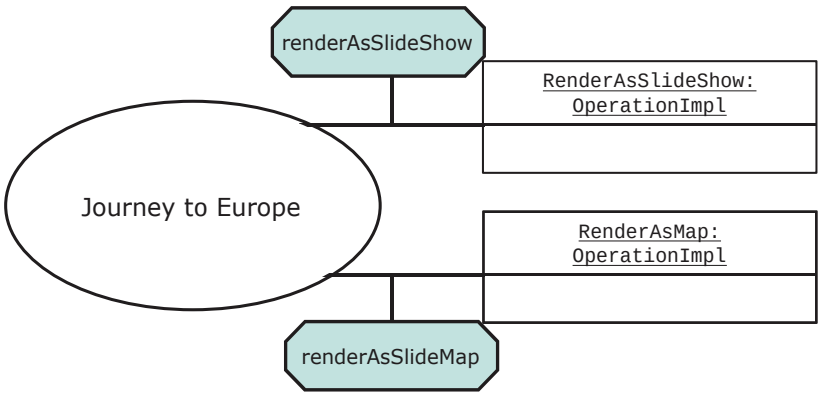


represented by the class of the same name. Each operation has a *designator*, that is, a name that describes its functionality, which is represented by an ontology object. Similar to attributes, the motivation behind using concepts of an ontology as operation designators instead of simple string identifiers is that this allows one to express restrictions on the usage of operations within an ontology; for example, the types of Emmo for which an operation is available, the types of the expected input parameters, and so forth.

The functionality of an operation is provided by a dedicated *implementation class* whose name is captured by an operation's implClassName attribute to permit the dynamic instantiation of the implementation class at runtime. There are not many restrictions for such an implementation class: the Emmo model merely demands that an

implementation class realizes the OperationImpl interface. OperationImpl enforces the implementation of a single method only: namely, the method execute() which expects the Emmo on which an operation is executed as its first parameter followed by a vector of arbitrary operation-dependent parameter objects. Execute() performs the desired functionality and, as a result, may return an arbitrary object.

Figure 15 once more depicts the Emmo modeling the photo album of the journey to Europe that we already know from Figure 13, but this time enriched with the two operations already envisioned in the second section: one that traverses the semantic description of the album returns an SMIL presentation that renders the album as a slide show, and another that returns an SVG presentation that renders the same album as a map. For both operations, two implementation classes are provided that are attached to the Emmo and differentiated via their designators renderAsSlideShow and renderAsMap.

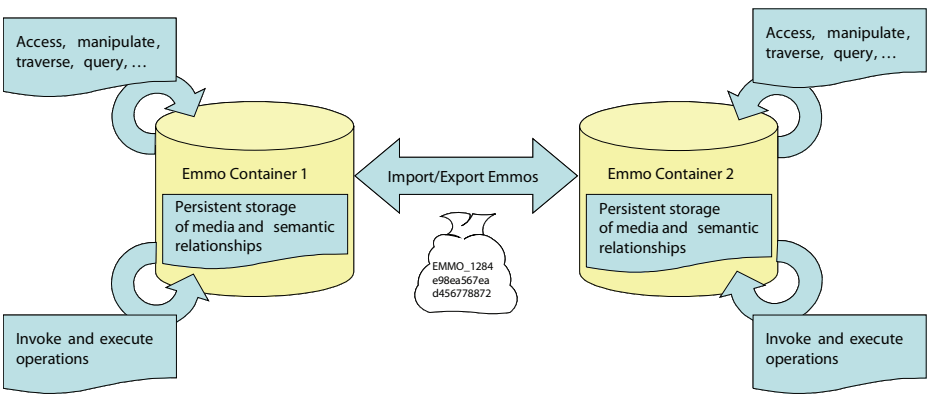
THE EMMO CONTAINER INFRASTRUCTURE

As an elementary foundation for the sharing and collaborative authoring of pieces of semantically modeled multimedia content on the basis of the Emmo model, we have implemented a distributed Emmo container infrastructure. Figure 16 provides an overview of this infrastructure, which we are going to describe in more detail in the following section.

Basically, an Emmo container provides a space where Emmos "live." Its main purpose is the management and persistent storage of Emmos. An Emmo container provides application programming interfaces that permit applications to fine-grainedly access, manipulate, traverse, and query the Emmos it stores. This includes the media aspect of an Emmo with its media profiles and instances, the semantic aspect with all its descriptional entities such as logical media parts, ontology objects, other Emmos, and associations, as well as the versioning relationships between those entities. Moreover, an Emmo container offers an interface to invoke and execute an Emmo's operations giving access to the functional aspect of an Emmo.

Emmo containers are not intended as a centralized infrastructure with a single Emmo container running at a server (although this is possible). Instead, it is intended to establish a decentralized infrastructure with Emmo containers of different scales and sizes running at each site that works with Emmos. Such a decentralized

Figure 16. Emmo container infrastructure



Emmo management naturally reflects the nature of content sharing and collaborative multimedia applications.

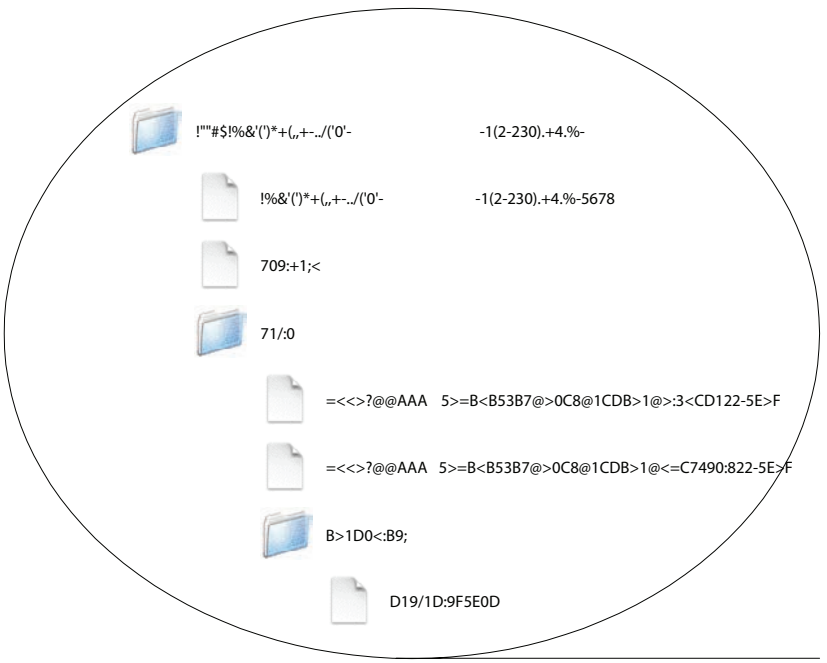
The decentralized approach has two implications. The first implication is that *platform independence* and *scalability* are important in order to support Emmo containers at potentially very heterogeneous sites ranging from home users to large multimedia content publishers with different operating systems, capabilities, and requirements.

For these reasons, we have implemented the Emmo containers in Java, employing the object-oriented DBMS ObjectStore for persistent storage. By Java, we obtain platform independence; by ObjectStore, we obtain scalability as there does not just exist a full-fledged database server implementation suitable for larger content providers, but also a code-compatible file-based in-process variant named PSEPro better suiting the limited needs of home users. It would have been possible to use a similarly scalable relational DBMS for persistent storage as well; we opted for an object-oriented DBMS, however, because of these systems' suitability for handling complex graph structures like Emmos.

The second implication of a decentralized infrastructure is that Emmos must be *transferable* between the different Emmo containers operated by users that want to share or collaboratively work on content. This requires Emmo containers to be able to completely export Emmos into bundles encompassing their media, semantic, and functional aspects, and to import Emmos from such bundles, which is explained in more detail in the following two subsections.

In the current state of implementation, Emmo containers are rather isolated components, requiring applications to explicitly initiate the import and export of Emmos and to manually transport Emmo bundles between different Emmo containers themselves. We are building a peer-to-peer infrastructure around Emmo containers that permits the transparent search for and transfer of Emmos across different containers.

Figure 17. Structure of an Emmo bundle



Exporting Emmos

An Emmo container can export an Emmo into a bundle whose overall structure is illustrated by Figure 17.

The bundle is basically a ZIP archive which captures all three aspects of an Emmo: the media aspect is captured by the bundle's media folder. The basic media files of which the multimedia content modeled by the Emmo consists are stored in this folder.

The semantic aspect is captured by a central XML file whose name is given the OID of the bundled Emmo. This XML file captures the semantic structure of the Emmo, thus describing all of the Emmo's entities, the associations between them, the versioning relationships, and so forth.

Figure 18 shows a fragment of such an XML file. It is divided into a <components> section declaring all entities and media profiles relevant for the current Emmo and a <links> section capturing all kinds of relationships between these entities and media profiles, such as types, associations, and so forth.

The functional aspect of an Emmo is captured by the bundle's operations folder in which the binary code of the Emmo's operations is stored. Here, our choice for Java as the implementation language for Emmo containers comes in handy again, as it allows us to transfer operations in form of JAR files with platform-independent bytecode even between heterogeneous platforms.

The export functionality can react to different application needs by offering several export variants: an Emmo can be exported with or without media included in the bundle, one can choose whether to also include media that are only referenced by URIs, the predecessor and successor versions of the contained entities can either be added to the bundle or omitted, and it can be decided whether to recursively export Emmos contained within an exported Emmo. The particular export variants chosen are recorded in the bundle's manifest file.

In order to implement these different export variants, an Emmo container distinguishes three different *modes* of how entities can be placed in a bundle:

- The *strong* mode is the normal mode for an entity. The bundle holds all information about an entity including its types, attribute values, immediate predecessor and successor versions, media profiles (in case of a logical media part), contained entities (in case of an Emmo), and so forth.
- The *hollow* mode is applicable to Emmos only. The hollow mode indicates that the bundle holds all information about an Emmo except the entities it contains. The hollow mode appears in bundles where it was chosen not to recursively export encapsulated Emmo. In this case, encapsulated Emmos receive the hollow mode; the entities encapsulated by those Emmos are excluded from the export.
- The *weak* mode indicates that the bundle contains only basic information about an entity, such as its OID, name, and description but no types, attribute values, and so forth. Weak mode entities appear in bundles that have been exported without versioning information. In this case, the immediate predecessor and successor versions of exported entities are placed into the bundle in weak mode; indirect predecessor and successor versions are excluded from the export.

The particular mode of an entity within a bundle is marked with the mode attribute in the entity's declaration in the bundle's XML file (see again Figure 18).

Importing Emmos

When importing an Emmo bundle exported in the way described in the previous subsection, an Emmo container essentially inserts all media files, entities, and operations included in the bundle into

Figure 18. Emmo XML representation

```

its local database. In order to avoid duplicates, the container checks whether an entity with the same OID or whether a media file or JAR file already exists in the local database before insertion. If a file already exists, the basic strategy of the importing container is that the local copy prevails.

However, the different export variants for Emmos and the different modes in which entities might occur in a bundle — as well as the fact that in a collaborative scenario Emmos might have been concurrently modified without creating new versions of entities — demand a more sophisticated handling of duplicate entities on the basis of a timestamp protocol. Depending on the modes of two entities with the same OID in the bundle, and the local database and the timestamps of both entities, essentially the following treatment is applied:

- A greater mode (weak < hollow < strong) in combination with a more recent timestamp

always wins. Thus, if the local entity has a greater mode and a newer timestamp, it prevails, and the entity in the bundle is ignored. Similarly, if the local entity has a lesser mode and an older timestamp, the entity in the bundle completely replaces the local entity in the database.

- If the local entity has a more recent timestamp but a lesser mode, additional data available for the entity in the bundle (entity types, attribute values, predecessor or successor versions, encapsulated entities in case of Emmos, or media profiles in case of logical media parts) complements the data of the local entity, thereby raising its mode.
- In case of same modes but a more recent timestamp of the entity in the bundle, the entity in the bundle completely replaces the local entity in the database.
- In case of same modes but a more recent timestamp of the entity in the local database, the entity in the database prevails and the entity in the bundle is ignored.

APPLICATIONS

Having introduced and described the Emmo approach to semantic multimedia content modeling and the Emmo container infrastructure, this section illustrates how these concepts have been practically applied in two concrete multimedia content sharing and collaborative applications. The first application named CULTOS is in the domain of cultural heritage and the second application introduces a semantic jukebox.

CULTOS

CULTOS is an European Union (EU)-funded project carried out from 2001 to 2003 with 11 partners from EU-countries and Israel1. It has been the task of CULTOS to develop a multimedia collaboration platform for authoring, managing, retrieving, and exchanging *Intertextual Threads* (ITTs) (Benari et al., 2002; Schellner et al., 2003) — knowledge structures that semantically interrelate and compare cultural artifacts such as literature, movies, artworks, and so forth. This platform enables the community of intertextual studies to create and exchange multimedia-enriched pieces of cultural knowledge that incorporate the community's different cultural backgrounds — an important contribution to the preservation of European cultural heritage.

ITTs are basically graph structures that describe semantic relationships between cultural artifacts. They can take a variety of forms, ranging from spiders over centipedes to associative maps, like the one shown in Figure 19.

The example ITT depicted in the figure highlights several relationships of the poem "The Fall" by Tuvia Ribner to other works of art. It states that the poem makes reference to the 3rd book of Ovid's "Metamorphoses" and that the poem is an ekphrasis of the painting "Icarus' Fall" by the famous Dutch painter Breugel.

The graphical representation of an ITT bears strong resemblance to well-known techniques for knowledge representation such as concept graphs or semantic nets, although it lacks their formal rigidity. ITTs nevertheless get very complex, as they commonly make use of constructs such as *encapsulation* and *reification* of statements that are challenging from the perspective of knowledge representation.

Encapsulation is intrinsic to ITTs because intertextual studies are not exact sciences. Certainly, the cultural and personal context of a researcher affects the kind of relationships between pieces of literature he discovers and are of value to him. As such different views onto a single subject are highly interesting to intertextual studies, ITTs themselves can be relevant subjects of discourse and thus be contained as first-class artifacts within other ITTs. Figure 20 illustrates this point with a more complex ITT that interrelates two ITTs

Figure 19. Simple intertextual thread

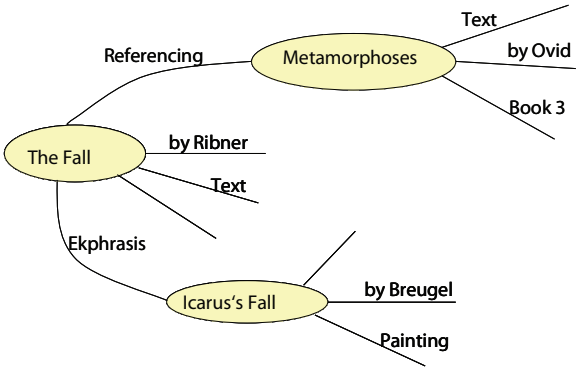

Figure 20. Complex intertextual thread

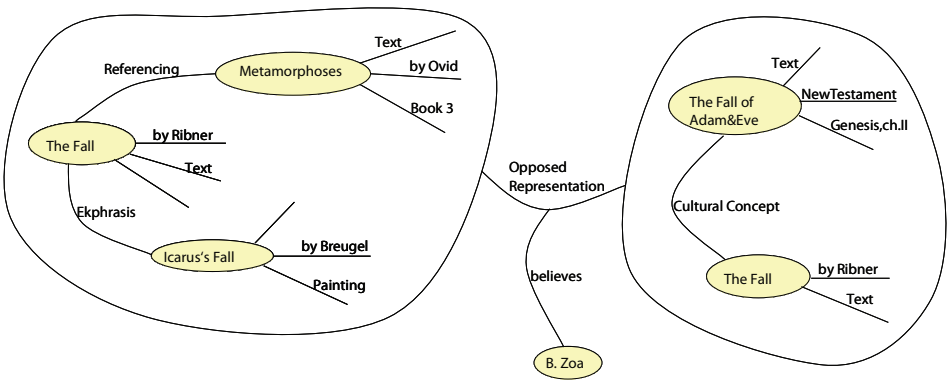

manifesting two different views on Ribner's poem as opposed representations.

Reification of statements is also frequently occurring within ITTs. Since experts in intertextual studies extensively base their position on the position of other researchers, statements about statements are common practice within ITTs. In the ITT of Figure 20, for instance, it is expressed by reification that the statement describing the two depicted ITTs as opposed representation is only the opinion of a certain researcher B. Zoa.

Given these characteristics of ITTs, we have found that Emmos are very well suited for their representation in the multimedia collaboration platform for intertextual studies that is envisioned by CULTOS. Firstly, the semantic aspect of Emmo offers sufficient expressiveness to capture ITTs. Figure 21 shows how the complex ITT of Figure 20 could be represented using Emmos. Due to the fact that associations as well as Emmos themselves are first-class entities, it is even possible to cope with reification of statements as well as with encapsulation of ITTs.

Secondly, the media aspect of Emmos allows researchers to enrich ITTs that so far expressed interrelationships between cultural artefacts on an abstract level with digital media about these artefacts, such as a JPEG image showing Breugel's

painting, Icarus' Fall. The ability to consume these media while browsing an ITT certainly enhances the comprehension of the ITT and the relationships described therein.

Thirdly, with the functional aspect of Emmos, functionality can be attached to ITTs. For instance, an Emmo representing an ITT in CULTOS offers operations to render itself in an HTML-based hypermedia view.

Additionally, our Emmo container infrastructure outlined in the previous section provides a suitable foundation for the realization of the CULTOS platform. Their ability to persistently store Emmos as well as their interfaces which enable applications to fine-grainedly traverse and manipulate the stored Emmos and invoke their operations make Emmo containers an ideal ground for the authoring and browsing applications for ITTs that had to be implemented in the CULTOS project. Figure 22 gives a screenshot of the authoring tool for ITTs that has been developed in the CULTOS project which runs on top of an Emmo container.

Moreover, their decentralized approach allows the setup of independent Emmo containers at the sites of different researchers; their ability to import and export Emmos with all the aspects they cover facilitates the exchange of ITTs, including the media by which they are enriched as well as the functionality they offer. This enables researchers to share and collaboratively work on ITTs in order to discover and establish new links between artworks as well as different personal and cultural viewpoints, thereby paving the way to novel insights to a subject. The profound versioning within the Emmo model further enhance this kind of collaboration, allowing researchers to concurrently create different versions of an ITT at different sites, to merge these versions, and to highlight differences between these versions.

Semantic Jukebox

One of the most prominent (albeit legally disputed) multimedia content sharing applications is the sharing of MP3 music files. Using peer-to-peer file sharing infrastructures such as Gnutella, many users gather large song libraries on their home PCs which they typically manage with one of the many jukebox programs available, such as Apple's

Figure 21. Emmo representing an ITT

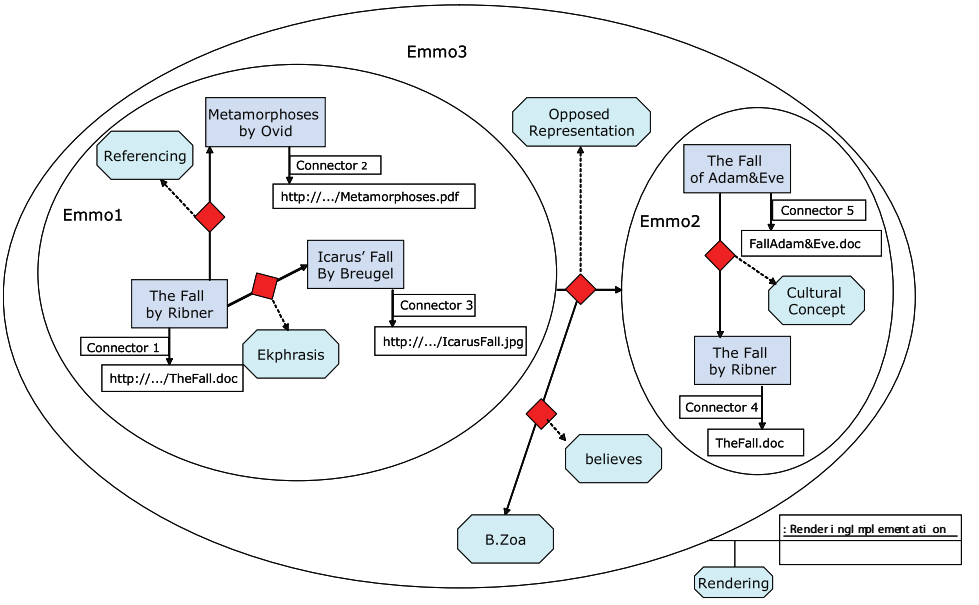

Figure 22. CULTOS authoring tool for ITTs

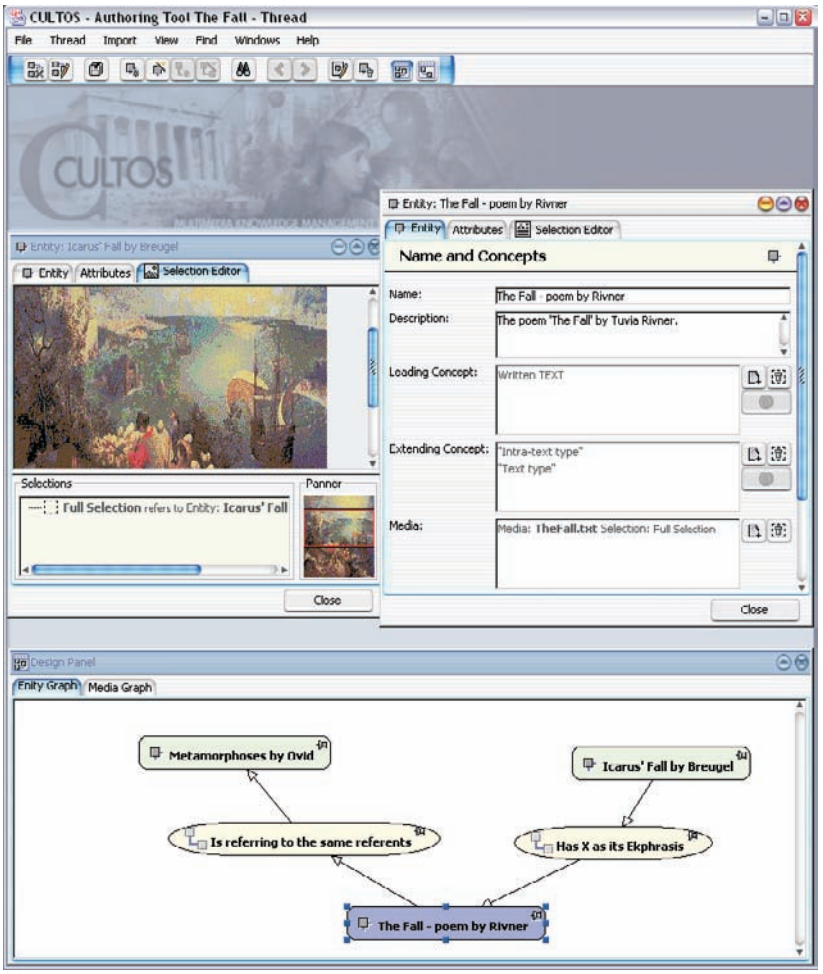
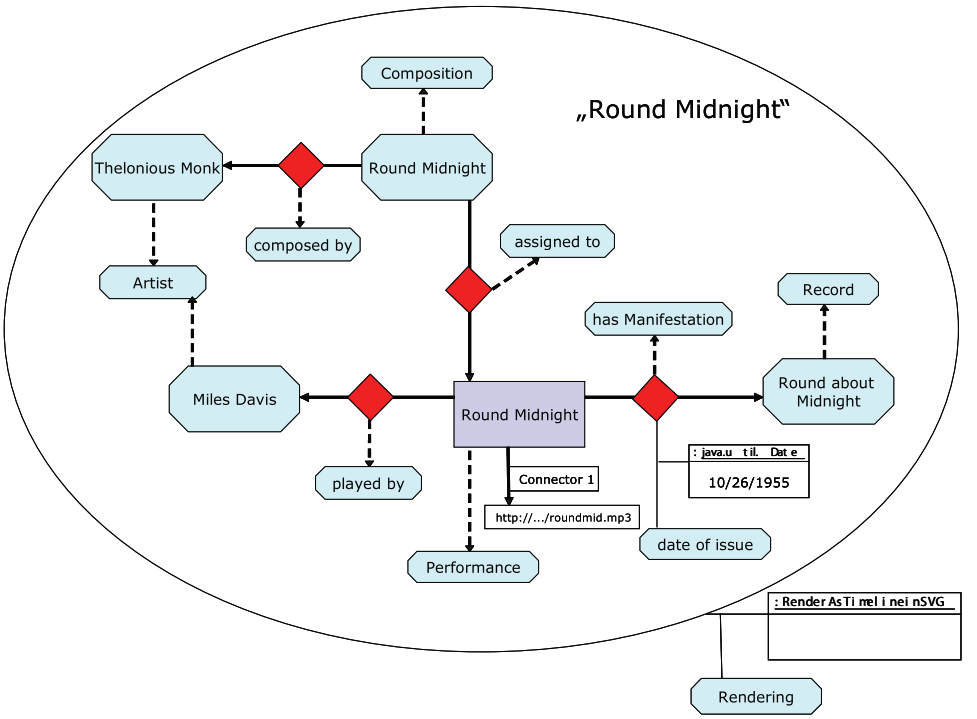


iTunes (Apple Computer, n.d.). The increasing use of ID3 tags (ID3v2, n.d.) — optional free text attributes capturing metadata like the interpreter, title, and the genre of a song - within MP3 files for song description alleviates the management of such libraries.

Nevertheless, ID3-based song management quickly reaches its limitations. While ID3 tags enable jukeboxes to offer reasonably effective search functionality for songs (provided the authors of ID3 descriptions spell the names of interprets, albums, and genres consistently), more advanced access paths to song libraries are difficult to realize. Apart from other songs of the same band or genre, for instance, it is difficult to find songs similar to the one that is currently playing. In this regard, it would also be interesting to be able to navigate to other bands in which artists of the current band played as well or with which the current band appeared on stage together. But such background knowledge cannot be captured with ID3 tags.

Using Emmos and the Emmo container infrastructure, we have implemented a prototype

Figure 23. Knowledge about the song "Round Midnight" represented by an Emmo



of a *semantic* jukebox that considers background knowledge about music. The experience we have gained from this prototype shows that the Emmo model is well-suited to represent knowledge-enriched pieces of music in a music sharing scenario. Figure 23 gives a sketch of such a music Emmo which holds some knowledge about the song "Round Midnight."

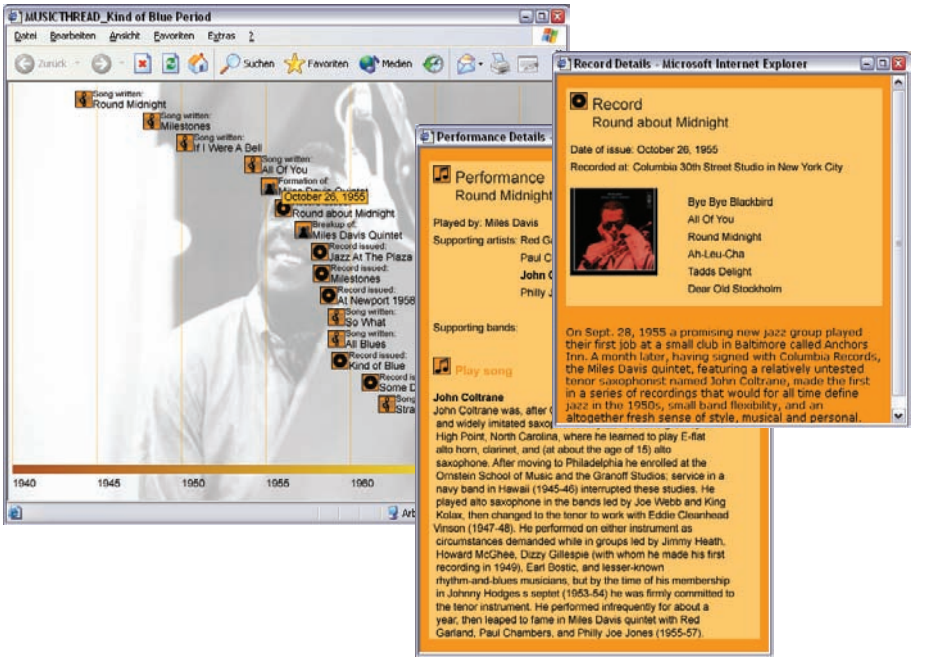
Its media aspect enables the depicted Emmo to act as a container of MP3 music files. In our example, this is a single MP3 file with the song "Round Midnight" that is connected as a media profile to the logical media part Round Midnight in the center of the figure.

The Emmo's semantic aspect allows us to express rich background knowledge about music files. For this purpose, we have developed a basic ontology for the music domain featuring concepts such as "Artist", "Performance", "Composition", and "Record" that all appear as ontology objects in the figure. The ontology also features various association types which allow us to express that "Round Midnight" was composed by Thelonious Monk and the particular performance by Miles Davis can be found on the record "Round about Midnight".

The ontology also defines attributes for expressing temporal information like the issue date of a record.

The functional aspect, finally, enables the Emmo to support different renditions of the knowledge it contains. To demonstrate this, we have realized an operation that, being passed a time interval as its parameter, produces an SVG timeline rendition (see screenshot of Figure 24) arranging important events like the foundation of

Figure 24. Timeline rendition of a music Emmo



bands, the birthdays and days of death of artists, and so forth, around a timeline. More detailed information for each event can be gained by clicking on the particular icons on the timeline.

Further operations could be imagined; for example, operations that provide rights clearance functionality for the music files contained in the Emmo, which is a crucial issue in music sharing scenarios.

Our Emmo container infrastructure provides a capable storage foundation for semantic jukeboxes. Their ability to fine-grainedly manage Emmos as well as their scalability allowing them to be deployed as both small-scale file-based and as large-scale database server configurations. Thus, Emmo containers constitute suitable hosts for knowledge-enriched music libraries of private users as well as libraries of professional institutions such as radio stations. Capable of exporting and importing Emmos to and from bundles, Emmo containers also facilitate the sharing of music between different jukeboxes. Their versioning support even allows it to move from mere content sharing scenarios to collaborative scenarios where different users cooperate to enrich and edit Emmos with their knowledge about music.

CONCLUSION

Current approaches to semantic multimedia content modeling typically regard the basic media which the content comprises, the description of these media, and the functionality of the content as conceptually separate entities. This leads to difficulties with multimedia content sharing and collaborative applications. In reply to these difficulties, we have proposed Enhanced Multimedia Meta Objects (Emmos) as a novel approach to semantic multimedia content modeling. Emmos

coalesce the media of which multimedia content consists, their semantic descriptions, as well as functionality of the content into single indivisible objects. Emmos in their entirety are serializable and versionable, making them a suitable foundation for multimedia content sharing and collaborative applications. We have outlined a distributed container infrastructure for the persistent storage and exchange of Emmos. We have illustrated how Emmos and the container infrastructure were successfully applied for the sharing and collaborative authoring of multimedia-enhanced intertextual threads in the CULTOS project and for the realization of a semantic jukebox.

We strive to extend the technological basis of Emmos. We are currently developing a query algebra, which permits declarative querying of all the aspects of multimedia content captured by Emmos, and integrating this algebra within our Emmo container implementation. Furthermore, we are wrapping the Emmo containers as services in a peer-to-peer network in order to provide seamless search for and exchange of Emmos in a distributed scenario. We also plan to develop a language for the definition of ontologies that is adequate for use with Emmos. Finally, we are exploring the handling of copyright and security within the Emmo model. This is certainly necessary as Emmos might not just contain copyrighted media material but also carry executable code with them.

Chapter 2.4
Designing for Learning in Narrative Multimedia Environments

Lisa Gjedde
Danish University of Education, Denmark

ABSTRACT

Narrative is fundamental for learning and the construction of meaning. In the design of interactive learning programs, the need for narrative is often neglected, and the emphasis is on information design rather than the design of experiential learning environments. This chapter presents research related to the development of two prototypes of narrative interactive multimedia learning environments, from an experiential and situated learning perspective and proposes a model for a narrative learning process, related to a situated and experiential learning perspective.

BACKGROUND

Narrative is fundamental for the construction of meaning on a personal as well as on a community level. The narrative format has been a traditional way of teaching in many cultures, and teachers may develop a competence as storytellers, drawing on narrative for motivation, and for experiential and contextual learning by using stories or having the learner's develop stories themselves (Gudmundsdottir, 1991). The concept of narrative encompasses both the narrative expression in the form of story-making and narrative as a cognitive tool for the construction of knowledge, which includes the construction of culturally embedded

knowledge as well as being an important part of knowledge sharing (Bruner, 1990; Schank, 1995). It also plays an important part in collaborative and experiential learning. The concept of situated and collaborative learning has been put forth by Brown, Collins, and Duguid, (1989) in their seminal article on Situated Cognition and the Culture of Learning: "Learning, both outside and inside school, advances through collaborative social interaction and the social construction of knowledge." The role of narrative in this learning process is important for distributed and embedded knowledge.

NARRATIVE AND MULTIMEDIA

Research into interactive multimedia as a resource for instruction and learning has previously pointed to problems in the organization and presentation of the material in relation to the cognitive processes of the students. Researchers from the MENO-project (Multimedia in Education and Narrative Organisation), located at the Open University and University of Sussex, have been investigating the role of narrative in relation to comprehension and learning in interactive multimedia, based on findings that the degree of narrative structure would affect the learners' level of comprehension. They found (Laurillard et al., 1998) that "learners working on interactive media with no clear narrative structure display learning behaviour that is generally unfocused and inconclusive." Based on a hypothesis of narrative as fundamental for learning, they designed an experimental study with three versions of material on a CD-ROM, with different degrees of narrative structure, and tested the different versions in classroom settings. The CD-ROM offered video sequences and a notepad for collecting material as well as questions to guide the exploration. Their conclusions point to the importance of designing interactive multimedia environments (Plowman et al., 1999), "so learners are able to both find narrative coherence and generate it for themselves." Groundbreaking cognitive psychologist and AI-researcher Roger Schank (1995), has likewise found narrative reasoning and construction to be fundamental for cognitive processes. At a theoretical level, Schank (with Abelsson) has contributed seminally through his cognitive models of goals, scripts, and plans. At the level of development and research, he has developed several prototypes and multimedia training programs that draw on narrative elements like case stories. He has advocated different learning architectures, which offers the possibility for sharing knowledge and natural learning and that stories can be used as a fundamental mode of communication and learning not only in case-based learning architectures but also in exploratory and incidental learning. Schank's prototypes of learning architectures with their call for life-like learning situations can be seen as exponents for experiential learning (Schank & Cleary, 1995).

The above-mentioned projects focused on their exploration of narrative in relation to educational and cognitive processes. They, however, do not provide prototypes that afford an exploration of the potentials of learning in an open environment, where the learner's own production of multimedia narratives is supported by offering multimedia tools.

Experiential learning is most often characterized by learning from primary experience. In relation to the research projects presented here, it is suggested that a fictional and imagination-based experience may offer a context for experiential learning that may provide material for expression and reflection. An influential model for experiential learning, which has been developed by David A. Kolb, draws on the work of John Dewey and Jean Piaget. However, in relation to the development of principles for the design of narrative interactive learning environments, it is important to include a focus on the situated and social aspects of the learning process.

There are potential learning advantages to be gained by constructing multimedia learning environments, not primarily as way of presenting encyclopedia-style factual material, but rather through offering the learners an experiential pathway into the material. It is further suggested that this may be enhanced by providing a narrative experience through a narrative framework, through narrative visual elements, as well as offering multimedia tools for narrative construction.

This chapter raises some questions related to the development of such prototypes of narrative interactive multimedia learning environments from an experiential and situated learning perspective and suggests a model for a narrative learning process, related to a situated and experiential learning perspective.

DESIGN OF NARRATIVE INTERACTIVE LEARNING ENVIRONMENTS

Designers of educational interactive multimedia programs are facing a challenge as to how to design learning environments that may enhance the collaborative learning that is situated as well as cognitive, through the use of narrative in the design and content. They are also facing the challenge of how to engage the learner in interactive experiences that are meaningful at the level of participation and expression of the learner. The participation may be in an immersive experience that allows the learner to actively engage in the action or to identify with the protagonist of the story. It may also be an experience with elements of role-playing, where the learner takes the action forward by using imagination as well as factual knowledge, and thus interacts by moving the story line forward. Engaging the learner in an imaginative productive way, where the learner is guided to participate in the development of the narrative plot and contribute to the development of the story, may be a way of engaging the learner at multiple levels of involvement.

Often, the use of story in education presents the teacher in a role as storyteller and the students as listeners that follow the unfolding of the narrative. The use of narrative in educational media calls for ways to engage the learner in a process of narrative that is meaningful and fully draws on the possibilities of the media for creation of media expression by the user, and thus for engaging the learner at different levels.

By placing the learner in the role as a storyteller, the learning context becomes one that may enhance the level of involvement as well as the inclusiveness of the situation, as the learner may approach the task from a different point of view and use different modalities of expression: images, sound, movement, etc.

Another issue to be explored in the development of narrative multimedia learning environments concerns the creation of content that is meaningful, that may be engaging for the learner and takes into consideration possible differences in gender-specific interests and social and cultural backgrounds.

Some of these issues related to the development of an architecture and design for narrative based on principles for experiential and situated learning, with the creation of authentic tasks, have been explored in two research projects funded by the Danish Ministry of Education, as part of a program to further the development and research of the use of ICT in schools.

PARTICIPATORY CONTENT DESIGN

The Narrative Universes of Children

This project is on the creation of content and the design of interactive multimedia narratives by children within the Danish Language and Art curriculum. The project involved students of Grades 4 to 6 in a study drawing on principles of participatory design. Four classes at four different schools, numbering about 100 students and

six teachers, participated in this project, which aimed at exploring children's narrative universes and their narrative construction and collaboration in multimedia productions and the creation of content design supporting that.

The research design included two separate phases. The first phase was an investigation of the narrative universes, which the children in this age group produced, when prompted to produce stories and develop imagery to illustrate them. The children produced stories and drawings, working in groups, for a period of weeks. They were allowed to use different modes of expression, ranging from making giant storybooks to be used for the kindergarten pupils, to the use of tape recorders and puppet theatre. The main purpose with this first phase was to prompt the creation of narrative material in order to inform the design process for the animation program. In this way, the learners would help create relevant content material, which subsequently could be used in relation to the animation program they were to use in the second phase.

The second phase focused on the learner's construction of interactive narratives using a simple animation program that allowed for production of interactive multimedia narratives by the learners. Based on the analysis of the stories and narrative universes created by the children during the first phase, a series of narrative universes was developed by the researchers based on the content created by the children. These universes were then produced into graphic material, by professional artists, in order to be used by the learners in the animation program.

The animation program allowed the learner to use these images and also to construct and modify the images and animations and the use of text and sound. This led to the creation of a rich material of interactive stories provided by the learners as well as classroom observation of their collaborative processes in their construction of the interactive narratives. This process in which most of the students where highly motivated, led to other processes of informal collaborative learning leading to mastery of the program and production of the story in which they were involved.

The collaborative learning was expressed in the creation of shared environments, with narrative elements, e.g., characters, settings, and themes. The program aimed at creating a context that would support the development of the learners' narrative competences and their construction of interactive narratives that were relevant to them, and it would also support their sharing of experiences. A further analysis of this rich material may reveal more of the learner's strategies for developing interactive media literacy and expressive nonlinear narrative competencies, and how this type of learning environment may support situated and collaborative learning and knowledge construction.

NARRATIVE FRAMEWORK – NARRATIVE EXPRESSION

Another project related to the development and research of narrative multimedia learning environments is the project "Narrative in interactive Web-based learning environments." This project explores the interplay between the narrative context that includes a narrative setting, with access to resources including stills, audio, and text, and the learner's collaborative production of narratives using these resources. The prototypes are produced and explored as action research using a qualitative methodology. It is an iterative design process involving an educational setting with three secondary schools with students in Grades 8 and 9.

In order to facilitate this process of collaborative learning, it is important that the context be motivating and appealing and that it offer familiar and interesting figures, settings, and issues that may be the frame for further exploration and narrative development relating to that theme (Gjedde, 2002). Part of the development

Figure 1. Multimedia narrative interface

of the script for the frame narrative included the showing of documentary film material from the historical period that this multimedia learning program addressed. This film was shown to the target group of Grade 8 students, and they were asked to fill out a questionnaire, subsequently, that focused on the different content areas of the film about the German occupation of Denmark during the Second World War, rating it for interest. The questionnaire and discussion of the film showed gender-specific preferences for the subjects. These were addressed in the development of the script for the frame narrative in order to provide content material, which would be interesting and motivating for the different students in relation to their preferences.

The illustrations that are used in this Web-based interactive multimedia program were made by an award-winning Danish artist. By applying a certain aesthetic expression on purpose, they are meant to address the target group and help create an immersive experience.

Figure 1 shows part of the room, which is the main interface in the program. It is navigable at 360 degrees, allowing the learner to explore the room and the artifacts, which are related to the narrative learning process.

Most of the artifacts are interactive and will open up to the activities that are available in this learning environment. The activation of the picture over the desk, which is indicated on the figure, will take the learner into the frame narrative. The frame narrative will guide the learner through some fictional but historically correct episodes, and lead the learner to some questions to continue the storytelling, either from the point of view of the male or female protagonist. The book on the table will provide access to a specially designed Web builder. Through this production tool, material from the databases holding sound and image files can be integrated in the Web-based multimedia stories produced by the learners. All the relevant source materials and production tools can be accessed as artifacts in the room, being held, for instance, in the cupboard, the book on the table, and the phone. This coherence between the graphic interface and the narrative environment is done in order to provide for a *pervasive narrative experience*, in which all actions and all materials are embedded in the context of the frame narrative. This is done in order to support the use of a narrative logic and narrative reasoning involved in the narrative experience, which provides for a shared learning environment that may facilitate

the building of stories involving shared knowledge and experience in a community of practice.

TOWARD A NARRATIVE LEARNING PROCESS

Storytelling and the use of narrative in interactive multimedia programs can offer ways of engaging with the material at different levels. The narrative elements and the way they are embedded in an interactive learning environment can serve as cognitive artifacts, which support the construction of meaning through structure, content, and culturally implicated values. The narratives offer immersive experiences, which allow the user to engage at an emotional level and involve the user with different emotional states.

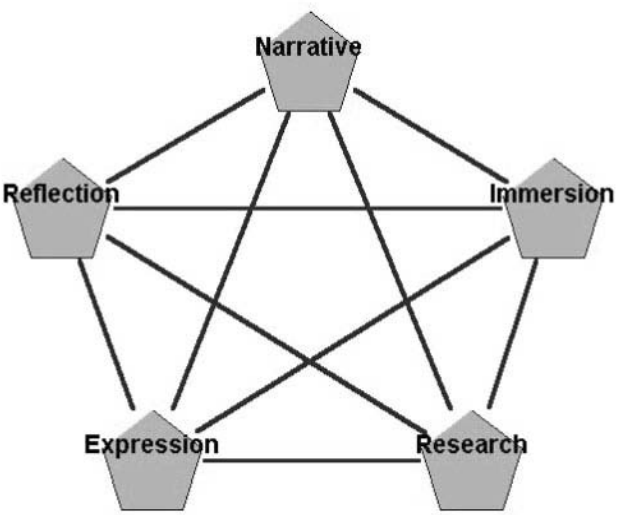
Developing and producing stories stimulates narrative thinking and a sense of causal relationships and analogy. It brings about possibilities for identification with the characters and situations, and in this way, it allows for multiple perspectives on situations and different points of view that are essential social skills. The development of this level of understanding and the competence to interpret and construct meaning are important skills and values in terms of the personal development and sense of cultural identity and personal values of the learner.

The stories offer materials for interpretation and reflection, and a shared cultural environment for doing so. In the interactive learning environment, the reflective process is distributed by the use of interactive log books and online conferences that allows for reflection on the process and productions.

The narrative learning process is framed by stories that are contextual, that make up the shared conceptual learning environment, which is characterized by its setting, characters, actions, and themes. The learner's development of the stories may lead to a process of research into the elements and factual material that are necessary for the unfolding of the story. The process of the articulation of the narratives in an interactive multimedia production may lead to the sharing of knowledge in a way that is socially and cognitively inclusive.

Through the narrative expression and articulation in digital media, a process that is experiential as well as situated in communities of practice, may

Figure 2. Narrative learning process



be initiated. This model on a narrative learning process is presented in Figure 2.

The model for the narrative learning process in the interactive multimedia learning environment described above, involves five distinct learning approaches and activities that are interrelated and mutually supportive. This model suggests a process of dynamic learning in which the elements are synergically related:

1. *Narrative*. The top point of the pentad refers to the concept of narrative that is based on the premise that narrative is an important experiential and contextual frame and approach to learning. It relates to the narrative content as well as to the organizing narrative structure.
2. *Immersion*. The concept of immersion is related to the experience of narrative content and structure. It is through the story and the related imaginative story elements that the learner experiences the immersion. It may be experienced further in the learning process as immersion in the subject matter and a research activity that is then expressed in the learner's own narrative articulation.
3. *Research*. The activity of research is a learner-directed activity delving into information and themes related to the narrative and the curricular areas it is exploring. It is focused by the narrative and supported by the sense of immersion into the subject.
4. *Expression*. The activity of expression is based on the research activity and is held in line by the narrative, which is the context it relates to and it further elaborates on or uses as a base for the construct of new narratives. It is also supported by the sense of immersion into the narrative context and characters.
5. *Reflection*. This activity can be a reflection by the learners on the material presented in narrative or nonfiction form, as well as on the narrative expression produced by the fellow learners. It is thus offering the teacher an avenue for reflecting on the learners' concepts as they are expressed in narrative form. It can encompass a hermeneutic as well as an aesthetic, imaginative, and expressive process.

These above-mentioned points are relevant parameters to include in the evaluation of the learning potentials of narrative interactive learning environments. Key questions to be asked in such an evaluation include the following:

- To what extent does the narrative interactive learning environment offer a narrative experience with a content that is relevant, engaging, and pervasive?
- Does it provide tools for the learner to participate in a process of articulation?
- Is it to be used with a learning scenario that includes a process of reflection?
- What roles does it offer the learner and the teacher?

CONCLUSION

Experiential and narrative learning processes move the focus from the instructor toward the learner. It moves it from the transfer of information, toward the hermeneutic process of interpretation and construction of meaning. By building architectures for learning in interactive multimedia environments that take into account the hermeneutic narrative process and the expressive narrative process, reflection on the learner's own expression is included.

Principles for the development of narrative multimedia learning environments must ideally be based on educational and psychological principles as well as on including production theory, in order to offer the potentials for a satisfactory learning experience.

Using the approach of narrative learning may further the knowledge of how to design and make available an interactive multimedia learning environment that can support the learner toward the understanding of the events and the meaning they hold and not just aim at achieving knowledge of factual events. Having this as the overarching learning paradigm supporting the design, it may allow for the learners to enter into levels of learning in which they may be more likely to be involved at personal levels. Thus, the boundaries between formal and nonformal learning environments may be blurred and allow for the learners to be part of communities of practice that are situated in experiential settings and cater to their needs to express their own goals and learning.

ACKNOWLEDGMENT

The projects "The Narrative Universes of Children" and "Narrative in interactive Web-based learning environments" are funded by the Danish Ministry of Education, "ITMF-programme."

The project "The Narrative Universes of Children" has been carried out in collaboration with Leif Gredsted, Associate Professor, DPU.

ABSTRACT

This chapter describes the learning design of two multimedia modules which complement a problem-based learning health sciences curriculum. The use of student-centred, authentic learning design frameworks guide academics and instructional designers in the creative pedagogical design of learning resources. The chapter describes the educational context, learning design of two multimedia modules and suggests a number of strategies for improving the design and development of multimedia resources.

INTRODUCTION

This chapter examines the instructional design of two multimedia modules that utilize authentic learning interactions to teach medical, dental, and health science concepts. Interactive multimedia modules complement the broader goals of a problem-based learning curriculum and enrich the health science curriculum by addressing conceptually difficult content areas. It is essential that the learning design (Koschmann, Kelson, Feltovich, & Barrows, 1996) of self-directed learning modules "should be informed from its

inception by some model of learning and instruction" (p. 83). The use of student-centered learning approaches is becoming increasingly popular in medicine, dentistry, and health science curricula as the teaching of problem-based learning and case-based learning assure a close match with real-world clinical cases. This chapter outlines the educational context and then examines two multimedia modules that utilize a case-based learning design. As educators, it is essential that we articulate our learning design for educational interventions from the earliest stages so that we are able to integrate the module into the educational setting and also provide a framework for evaluating the innovation (Koschmann, Kelson, Feltovich, & Barrows, 1996).

EDUCATIONAL CONTEXT

The medical course at the University of Melbourne had traditionally been taught using a discipline-based approach. Internal review mechanisms and student feedback in recent years had highlighted a number of deficiencies in the traditional course. In broad terms, these included insufficient integration between the basic and clinical sciences, insufficient attention to teaching communication skills, problem-solving skills, and social aspects of health, and an overload of biomedical detail that was duplicated in subjects originating from different departments. In an effort to remedy these deficiencies and also to incorporate current theories of medical education, a new medical curriculum was introduced in 1999. The pedagogical model for the new medical curriculum incorporates elements of problem-based learning (PBL) and self-directed learning (SDL) (Koschmann, Kelson, Feltovich, & Barrows, 1996). The primary focus of learning in semesters 2 through 5 is through medical problems (known as problems of the week), which are presented to students in small group tutorial settings. A key feature of the new curriculum is the horizontal integration across disciplines and the vertical integration of clinical situations with basic scientific material (Keppell, Kennedy, Elliott, & Harris, 2001).

The transformation of a medical course by the faculty involved considerable analysis, planning, investment of resources, staffing, and fundamental changes to teaching and learning approaches. Changing a traditional teaching and learning approach to a PBL approach represented a major pedagogical shift for academics within the faculty. In addition to this fundamental change, the curriculum also placed considerable emphasis on Web-based and multimedia teaching resources. This major departure from a traditional medical curriculum required support from academic staff across a wide range of diverse disciplines. A number of researchers have examined the importance of context in supporting major change like the faculty's curricular transformation. According to Altschuld and Witkin (2000), the following was found:

> *…implementation of innovations required awareness on the part of and strong support from administrators, a dedicated and critical mass of staff working with the change, communication channels that were frequently used by that staff to promote change, and a climate that makes nonadopters feel as though they are "out of it" unless they begin to adopt or move forward* (p. 182)

These factors will make or break the implementation of the innovation.

Use of Information and Communication Technology in the Curriculum

The use of information and communication technology (ICT) is an important feature of the problem-based learning curriculum. ICT is utilized to deliver medical content in two ways.

These include the use of the Web-based problem of the week embedded in the TopClass learning framework and stand-alone, computer-facilitated learning modules. The TopClass learning framework provides a central access point for students to enter the online course work, complete self-assessment tests, view class announcements, participate in discussion groups, and send and receive messages from teachers or peers. In the first three years of the medical curriculum, the medical student needs to complete 60 problems of the week. Approximately 120 problems of the week will be required for the entire curriculum. Self-directed learning resources, in the form of computer-facilitated learning modules, are also required to support the core content of the problems. Approximately 70 modules are in use or are currently under development within the faculty, and it is envisaged that 100 modules will be required to support the curriculum in its entirety.

Self-directed learning resources have a unique role in the curriculum. These resources are often initiated by clinicians who teach conceptually difficult content areas. A conceptually difficult content area (usually one to two hours) is often identified and developed by academics and multimedia teams. For instance, a module on pediatric dentistry focusing on a diabetic child complements a dental curriculum; a module on sensitive examination technique (SET) cervical screening is used to complement the teaching of cervical cancer. These resources may be used independently of the PBL curricula or they may be developed to complement the content within a problem of the week. Often, these computer-facilitated learning modules support the core content of the problems. Figure 1 portrays the use of ICT in the curriculum and the use of computer technology to complement, enhance, and support teaching and learning in the curriculum. The focus of this chapter is on the self-directed learning component of Figure 1.

MULTIMEDIA AND ONLINE MODULES

Figure 2 shows the variety of modules developed by the faculty as of December 2002. Each content

Figure 1. Use of computer technology in the medical curriculum

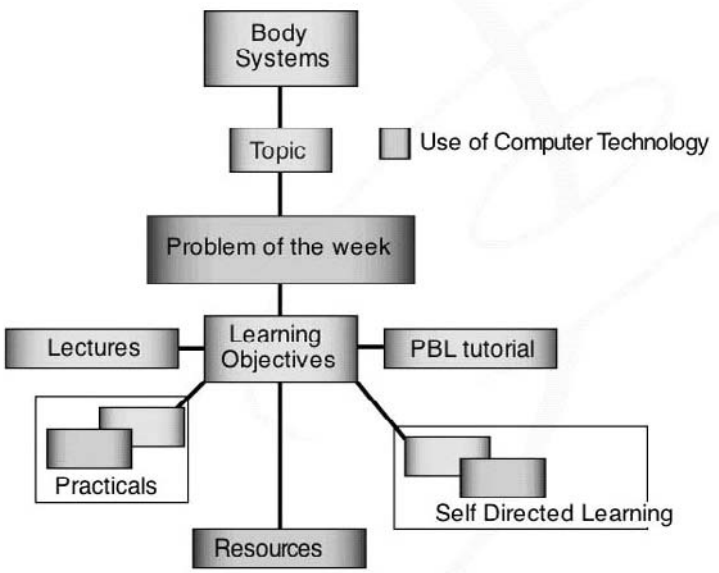

Figure 2. Multimedia and online modules utilized within the faculty

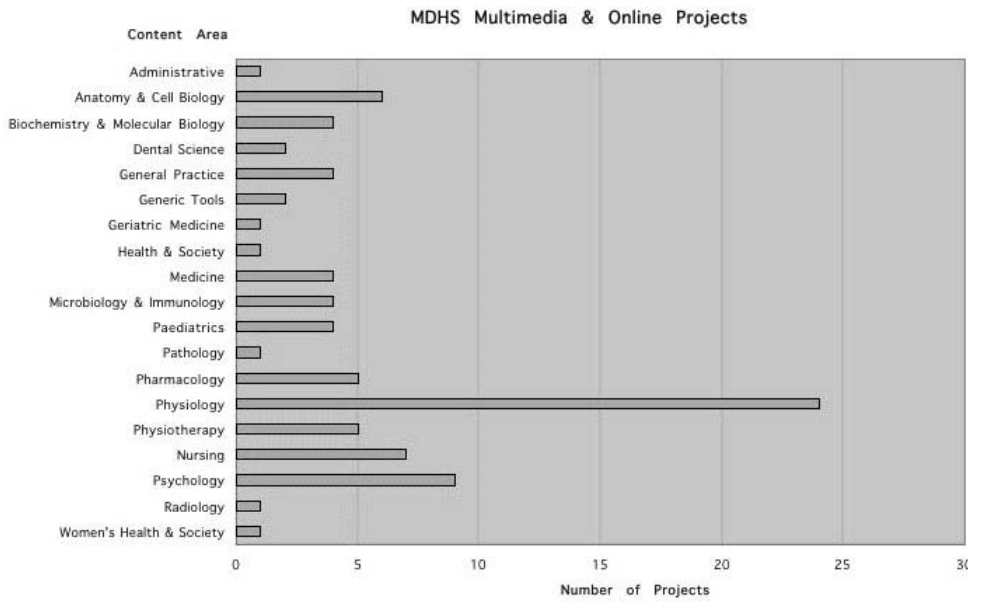

area is outlined with the number of modules per discipline area. This graphic provides an overview of the diversity of content areas that utilize multimedia to enhance teaching and learning. Many modules utilize student-centered teaching and learning approaches. In some instances, instructional designers have worked with the academics to develop their module utilizing constructivist teaching and learning principles, including case-based learning. The following aspects of this chapter examine the application of these principles to the design of two multimedia modules.

STUDENT-CENTERED LEARNING

There has been a trend away from teacher-directed instructional approaches to student-centered learning environments. Jonassen and Land (2000) compare the two methods in Table 1. In particular, in student-centered learning environments, contextualized, authentic, and situated learning interactions are emphasized. These principles have been adopted in the learning design of the two specific modules that will be discussed in this chapter, which utilize authentic learning interactions.

LEARNING DESIGN

Although, as stated in Herrington, Oliver, and Reeves (2002), "it is impossible to design truly authentic learning experiences" (p. 60), we attempted to develop learning experiences that would complement and enhance the professional practice of doctors and dentists. We considered a range of factors including the intent of the curriculum, lecturer teaching style, and learning outcomes in designing the multimedia modules. Authentic learning experiences, according to Jonassen, Mayes, and McAleese (1992), are "those which are problem- or case-based, that immerse the learner in the situation requiring him or her to acquire skills or knowledge in order to solve the problem or manipulate the situation" (p. 235).

Table 1. A comparision of instructive and student-centered learning environments

Instruction	Student-Centered Learning Environments
Transmission, acquisition	Interpretation, construction
Mastery, performance	Meaning making
External reality	Internal reality
Abstract, symbolic	Contextualized, authentic, experiential
Individually interpreted	Socially negotiated, coconstructed
Individual	Collaborative
Encoding, retention, retrieval	Articulation and reflection
Symbolic reasoning	Situated learning
Psychology	A nthropology, sociology, ethnography
Laboratory	in situ
Well-structured	Ill-structured
Decontexualized	Embedded in experience

Source: Adapted from Jonassen and Land (2000)

And, according to Young (1993), "Authentic tasks enable students to immerse themselves in the culture of the academic domain, much like an apprentice" (p. 43). Authentic learning contexts such as the virtual dental clinic and cervical screening module may have a number of advantages over more decontextualized teaching and learning settings. The authentic nature of the technology-enhanced, student-centered learning environment may anchor knowledge in authentic contexts. An effective learning environment enables learners to use its resources and tools to process more deeply and extend thinking (Jonassen, 1996; Jonassen & Reeves, 1996; Kozma, 1987).

In order to create realistic learning experiences for the students, it was essential that we immerse the student in authentic cases to guide our creation of the two modules. Herrington, Oliver, and Reeves (2002) outlined 10 characteristics of authentic activities. These comprise the following:

- Authentic activities have real-world relevance.

- Authentic activities are ill-defined, requiring students to define the tasks and subtasks needed to complete the activity.
- Authentic activities comprise complex tasks to be investigated by students over a sustained period of time.
- Authentic activities provide the opportunity for students to examine the task from different perspectives, using a variety of resources.
- Authentic activities provide the opportunity to collaborate.
- Authentic activities provide the opportunity to reflect.
- Authentic activities can be integrated and applied across different subject areas and lead beyond domain-specific outcomes.
- Authentic activities are seamlessly integrated with assessment.
- Authentic activities create polished products valuable in their own right rather than as preparation for something else.
- Authentic activities allow competing solutions and diversity of outcome.

Two modules will be analyzed to demonstrate how the above principles have been utilized to design authentic learning interactions. In the first instance, Tables 2 and 3 outline an overview of the principles and their concrete applications.

Authentic Activities have Real-World Relevance

In designing the two modules, we considered the "real-world tasks of professionals" (Herrington, Oliver, & Reeves, 2002, p. 62) as a basis for the module. For instance, in the field of pediatric dentistry, there are concerns that dental students are not competent in combining preventive and restorative management philosophies while integrating diagnosis and treatment planning (Suivinen, Messer, & Franco, 1998). Declining patient numbers and a need to focus on integration suggested that the use of multimedia case simulations were a viable alternative, as they replicate the dental clinic without requiring live patients. A module on diabetes and its implications for dentistry provides an opportunity to develop and consolidate the concept of integrated patient care. The diabetes case created unique challenges for the design team. A virtual pediatric diabetic patient was created in order to address the difficulty of obtaining relevant patient photographs. Our explicit learning design focused on increasing the level of student engagement with the content by contextualizing the scenario content within a virtual dental clinic (Keppell, Kan, Messer, & Bione, 2002).

The SET project attempts to examine a real-world clinical case of cervical screening so that medical students can decide which women should be screened on the basis of evidence-based screening recommendations. It also discusses the barriers to cervical screening from the patient's and doctor's perspectives and effective communication skills to explain how a Pap test is performed. Videos are sequenced to explain and demonstrate the steps involved in taking a Pap test and how to communicate the results to a woman. Currently, medical students have few opportunities to observe or perform Pap tests, and current literature documents negative screening experiences by women as a major barrier to participation in the cervical screening program. Participation in a cervical screening program has been shown to prevent most cases of cervical cancer (Keppell, Gunn, Hegarty, Madden, O'Connor, Kerse, & Judd, 2003).

Authentic Activities are Ill-Defined, Requiring Students to Define the Tasks and Subtasks Needed to Complete the Activity

In the SET project, we specifically attempted to engage the students by providing cases that the student would need to examine from a clinical

Table 2. Authentic learning design principles and their concrete applicatons within the design of the virtual dental clinic (see Figures 3 and 4)

Principle (Herrington, Oliver, & Reeves, 2002)	**Concrete Application (Virtual Dental Clinic)**
Authentic activities have real-world relevance.	• The clinical case on diabetes was developed in conjunction with experts from medicine and dentistry. • The virtual dental clinic was designed using photographs of the actual clinical setting. Photographs of the clinic were used to build the setting in order to keep the real-world relevance. • Actual case information from real-life patients was used to develop the scenario. This clinical information included actual photographs, radiographs, and medical case information in relation to a child with diabetes.
Authentic activities are ill-defined, requiring students to define the tasks and subtasks needed to complete the activity.	• The diabetes scenario is presented to the students as an actual case. They complete sections on patho-physiology, medical management, and dental management and then apply their knowledge in a realistic case. • There is no step-by-step sequence to completing the clinical case. Students are expected to determine the most appropriate strategies and sequence for completing the treatment plan. • The case information is accessible in any order. The students must make a decision as to the information they require at a particular point in the clinical case.
Authentic activities comprise complex tasks to be investigated by students over a sustained period of time	• The clinical case requires students to concentrate their energy toward the case for a period of approximately 45–60 minutes. • It is expected that the student would return to the case over a period of time as their knowledge is elaborated in the area.
Authentic activities provide the opportunity for students to examine the task from different perspectives, using a variety of resources.	• A wide variety of resources assist the student in obtaining an in-depth examination of the case. • These resources include the following: o Seven clinical photographs o Three radiographs o Patient history o Medical history o Dental history o Height/weight o Social history o Expert opinions from a teacher, psychologist, and endocrinologist.
Authentic activities provide the opportunity to collaborate.	• This module was created as a self-directed learning activity that is used by the professors in a lab setting. • Students complete the module and are provided with expert assistance as required. • Collaboration with other students is not explicit, although teaching staff could complete collaborative group activities at certain points in the tutorial.
Authentic activities provide the opportunity to reflect.	• Explicit reflective activities have not been included in the design of the module. • The use of questions immediately following the presentation of the virtual dental clinic may encourage students to backtrack and re-examine information. • The use of an electronic reflective journal at appropriate points would foster reflection. This feature may be considered at a future time.
Authentic activities can be integrated and applied across different subject areas and lead beyond domain-specific outcomes.	• This case is focused on dental students who will learn generic case-based strategies. • Generic skills of observation, analysis, synthesis, and professional practice would be fostered.
Authentic activities are seamlessly integrated with assessment.	• This is a major strength of the virtual dental clinic. • Students complete a treatment plan that contains all treatment procedures used by an Australian dentist. • The treatment plan encourages the students to re-examine the clinical information (case information, photographs, radiographs) and complete a legitimate treatment plan for the diabetes child. • Students submit their treatment plan and compare their plan to an expert treatment plan. • Students can confirm their treatment plan or re-examine the clinical photographs and radiographs to determine where they may have been incorrect in their initial judgement.
Authentic activities create polished products valuable in their own right rather than as preparation for something else.	• This module is valuable in its own right as a clinical case. Future cases may be developed around the virtual dental clinic. • The clinical case is also the fundamental interaction utilized by the dentist in clinical practice.
Authentic activities allow competing solutions and diversity of outcome.	• Students examine the clinical information and create a treatment plan based on their clinical judgement. • Students may clearly perceive all relevant clinical information and complete the case successfully. However, the design of the case encourages the student to backtrack and re-examine the clinical information and to adjust their treatment plans after submitting to obtain an expert treatment plan.

perspective. Topic 1 examines five mini-cases and provides perspectives on the barriers of cervical screening from the woman's different cultural background. Learners may have insufficient knowledge and will need to examine additional clinical information in the form of a glossary of key medical terms and the library that provides detailed information about cervical screening. This additional information may assist the student in interpreting and analyzing each case more effectively. Students can identify their own knowledge deficiencies and supplement

Table 3. Authentic learning principles and their concrete application in the design of the SET module (see Figures 5, 6, and 7)

Principle (Herrington, Oliver, & Reeves, 2002)	**Concrete Application (Cervical Screening Module)**
Authentic activities have real-world relevance.	• The clinical case on cervical screening was developed in conjunction with experts in medicine from three different universities in Australia and New Zealand. • State health departments involved in cervical screening also participated in the design of the module. • Topic 1 examines five cases from different cultural and ethnic backgrounds and the barriers that differ across these cultures. • Topics 2, 3, and 4 follow one woman into the communication, examination, and follow-up stages. • The virtual clinic was based on an actual clinical setting. Photographs of the clinic were used to build the setting in order to keep the real-world relevance. • Actual case information from real patients was used to build the scenario. This included actual photographs and video and case information in relation to medical history.
Authentic activities are ill-defined, requiring students to define the tasks and subtasks needed to complete the activity.	• The cervical screening cases presented in Topic 1 require the student to examine the different types of barriers of different women from different ethnic and cultural backgrounds. • Students should begin to understand the influence of personal factors, previous experience with cervical screening, and cultural norms in relation to treating different women in the clinical setting. • Questions are open-ended, which requires the student to examine a variety of information resources to determine appropriate responses. • The case information is available for students to access as needed. A glossary and library provide additional resources for examination.
Authentic activities comprise complex tasks to be investigated by students over a sustained period of time	• The clinical case requires students to concentrate their energy toward the case for a period of approximately 3–4 hours. • It is expected that the student would return to the case over a period of time as their knowledge is elaborated in the area. • The video examples of communication and examination provide a means for the student to view best-practice examples before clinical practice and as revision after clinical practice. Used in these two ways, the student should be able to reflect on appropriate strategies for improving the clinical practice of this sensitive area.
Authentic activities provide the opportunity for students to examine the task from different perspectives, using a variety of resources.	• A wide variety of resources assist the students in obtaining an in-depth examination of the case. • These resources include the following: o Clinical photographs o Video of ideal communication between the doctor and the woman o Video of ideal examination procedures o Patient history o Medical history o Social history o Expert opinions from practicing doctors o Definitions of key words in the glossary o Extended information in the library o Expert feedback
Authentic activities provide the opportunity to collaborate.	• This module was created as a self-directed learning activity and as an adjunct to the cervical screening program in Victoria. • It is expected that participants in the clinical screening program will discuss key issues and concerns using aspects of the module as a trigger for activities. • Collaboration with other students is not explicit at this point in time, although teaching staff could complete collaborative group activities at certain points in the tutorial.
Authentic activities provide the opportunity to reflect.	• Explicit reflective activities have been included in the design of the module. • A reflective notebook allows the students to document reflections and ideas throughout the module. This can be saved as an electronic file or printed out at the end of the session. The use of an electronic reflective journal at appropriate points would foster reflection. • Open-ended questions require the student to complete a detailed response before proceeding. This can be saved as an electronic file for future examination. • The use of questions immediately following the presentation of the video segments may encourage students to backtrack and re-examine information.
Authentic activities can be integrated and applied across different subject areas and lead beyond domain-specific outcomes.	• The module examines a difficult and sensitive area in which students may experience some awkwardness. • It is hoped that students will begin to learn skills in empathy and improve communication skills that can be applied to other sensitive areas in medical clinical practice, such as breast examinations. • Generic skills of observation, analysis, synthesis, and professional behavior would be fostered.
Authentic activities are seamlessly integrated with assessment.	• Formal assessment has not been determined. Future implementation will determine this assessment. • Self-assessment activities are embedded throughout the module. Students are asked to complete activities after viewing each video segment.
Authentic activities create polished products valuable in their own right rather than as preparation for something else.	• This module is valuable in its own right as a clinical case. • The clinical case is also the fundamental interaction utilized by the medical doctor in clinical practice.
Authentic activities allow competing solutions and diversity of outcome.	• Students examine the clinical information and create a schema for future medical consultation. • The design of the case encourages the student to backtrack and re-examine the clinical information.

their ideas via the additional resources provided (see Figure 8).

Authentic Activities Comprise Complex Tasks to be Investigated by Students over a Sustained Period of Time

SET will be used by universities in Australia and New Zealand to introduce the concepts of cervical screening and intimate examinations in a consistent way that emphasizes the importance of sensitive communication and examination skills. It should be noted that many students are nervous about performing intimate examinations, and the SET module will attempt to demystify the clinical process. Because the module focuses on communication skills in conjunction with clinical skills, students will need to examine the module over a period of time. Initially, students may obtain an overview of the cervical screening pathway before undertaking clinical practice. They may also revise certain sections after clinical practice. While practicing as a general practitioner, the doctor may revisit appropriate sections of the module and examine best-practice processes

Figure 3. Virtual dental clinic

Figure 4. Virutal dental office

Figure 5. Situated learning environment utilized for the SET Project–1

Figure 6. Situated learning environment utilized for the SET Project–2

and procedures in the field. For this reason, the four to five hour module will require sustained attention over a period of time and for different purposes. Specifically, the SET module will be utilized in different ways in the medical program of Melbourne, Queensland, and Auckland. The module will be used to compliment face-to-face teaching as well as allow students to explore the "learning loops" provided on SET both in the tutorial and self-directed learning (SDL) setting. The SET module will be available for students to use in the computer labs/PBL rooms at each site.

Authentic Activities Provide the Opportunity for Students to Examine the Task from Different Perspectives, Using a Variety of Resources

The use of different cases provides the students with an ability to examine different barriers

Figure 7. Situated learning environment utilized for the SET Project–3

Figure 8. Glossary utilized in the SET module

that may affect cervical screening. The library resources also provide additional information and a variety of resources that should assist the student (Herrington, Oliver, & Reeves, 2002) to "examine the problem from a variety of theoretical and practical perspectives, rather than allowing a single perspective that learners must imitate to be successful" (p. 281) (see Figures 9 and 10).

Authentic Activities are Ill-Defined, Requiring Students to Define the Tasks and Subtasks Needed to Complete the Activity

Both modules examine complex content areas in the areas of dentistry and medicine. Due to the complexity of the content, a range of resources pro-

vides definitions of key terms and more elaborate content in the library. Key dental, medical, and physiological concepts are defined in a glossary. Users can choose to browse all glossary terms or select specific terms that require clarification at the relevant point in the module. In addition, resources are provided in a library section in the SET module. The virtual dental clinic has a range of clinical images and case information available within the clinical setting, allowing students to access as required in the examination of the dental case. We specifically attempt to engage the students by providing cases that the student will need to examine from a clinical perspective. This means that they may need to search for relevant content in other sections of the module to achieve a deep understanding of the content.

Authentic Activities Comprise Complex Tasks to be Investigated by Students over a Sustained Period of Time

Each module focuses on 1 to 3 hours of difficult dental, clinical, and physiological content that is used to complement face-to-face teaching. The modules will also be used to support lectures by allowing lecturers to recommend that students examine the self-directed learning module located in a lab setting. The students may also be asked to utilize the modules as a revision tool before examinations. Because the modules focus on conceptually difficult content, they will require multiple exposure and viewing by the students. For example, students can review communication practices before they complete cervical screening in a clinical setting and then after clinical practice to review their communication and examination methods. Dental students can reinforce clinical treatment protocols in treating a pediatric dental patient by working through a legitimate case on diabetes.

Authentic Activities Provide the Opportunity for Students to Examine the Task from Different Perspectives, Using a Variety of Resources

Within the virtual dental clinic, we provide multiple entry points into the clinical information. This allows the user to explore the clinic and obtain the necessary clinical information about the patient. We wanted the student to "criss-cross the landscape of knowledge" in order to obtain information that will enable them to complete the relevant treatment plan (Young, 1993, p. 46). The user can navigate around the clinic and find information in two ways. By traveling around the clinic, they will find hotspots that provide clinical information. A site map also provides clinical information enabling the student to access patient records (patient information, medical history, height and weight, dental history, and social history), seven clinical slides, three radiographs, and expert information from a teacher, psychologist, and endocrinologist. By providing the necessary scaffolding for the novice learner, we attempt to move the learner toward expert case management (see Figure 11–14).

The use of different cervical screening cases provides the students with an opportunity to examine different barriers that may affect cervical screening. The library resources also provide additional information and a variety of resources that should assist the student (Herrington, Oliver, & Reeves, 2002) to "examine the problem from a variety of theoretical and practical perspectives, rather than allowing a single perspective that learners must imitate to be successful" (p. 281).

Authentic Activities Provide the Opportunity to Collaborate

Within the virtual dental clinic, the learning context allows the student to learn within an expert-supported learning environment. Lab

Figure 9. Clinical visuals and radiographs that can be enlarged for further detail within the virtual the virtual dental clinic

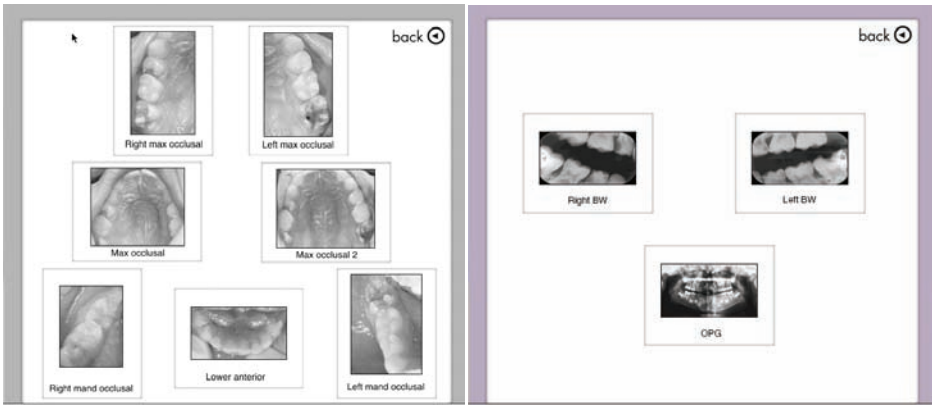

Figure 10. Library resources utilized by the student for additional clinical information about cervical screening

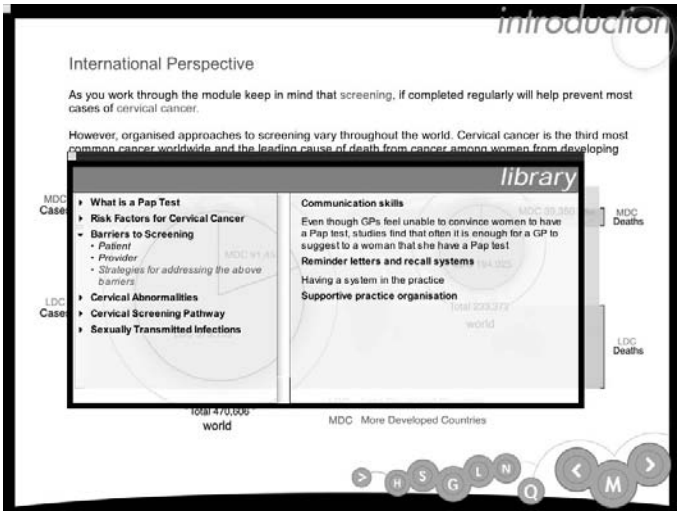

sessions have been scheduled in which students interact with the module and were supported by pediatric dentists. According to Young (1993), "From the perspective of situated cognition, the teacher's role should be to 'tune the attention' of students to the important aspects of the situation or problem-solving activity, specifically those attributes that are invariant across a range of similar problems and therefore will transfer to many novel situations" (p. 47). The advantage of utilizing expert support is that some information about the case can be clarified and explained by the expert tutors. Their roles in the learning process are as a coach, collaborator, and mentor for student learning. According to Choi and Hannafin (1995), coaching focuses on "directing

Figure 11. Student response to an open-ended question with an expert answer within the SET project

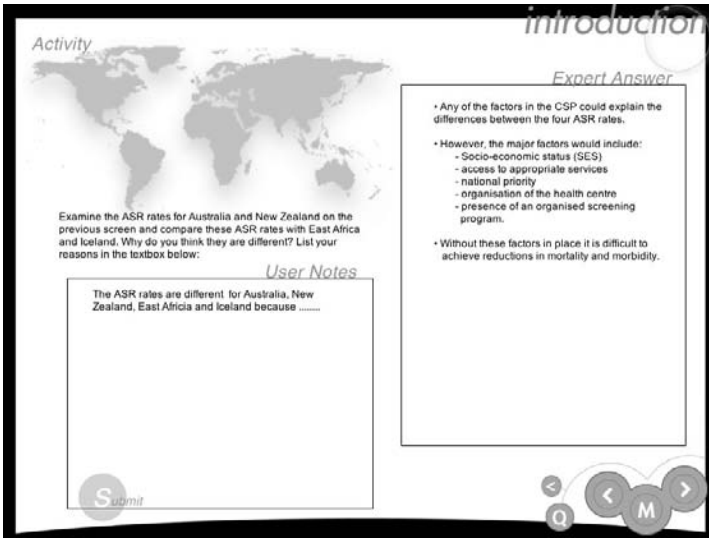

Figure 12. Reflective notebook utilized in the SET project

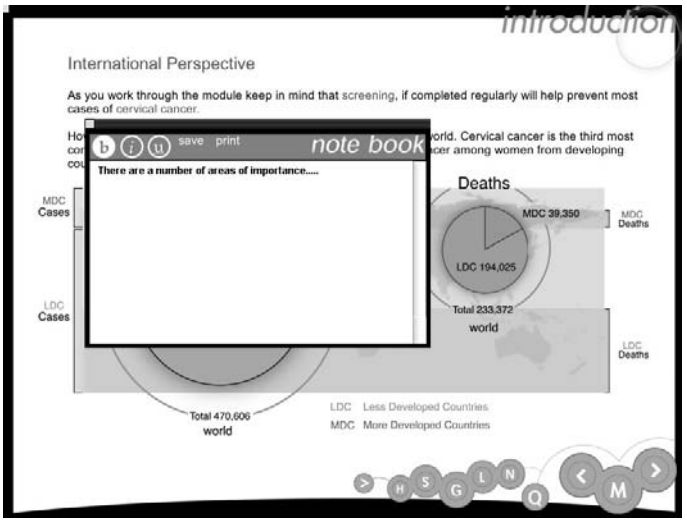

learner attention, reminding of overlooked steps, providing hints and feedback, challenging and structuring ways to do things, and providing additional tasks, problems, or problematic situations" (p. 62). The SET module will also be used in a collaborative setting.

Authentic Activities Provide the Opportunity to Reflect

Many of the activities embedded throughout the SET module ask the student to type in extended responses to questions. These responses are then submitted, and the student is provided with expert

Figure 13. Electronic treatment plan utilized for the diabetes clinical case

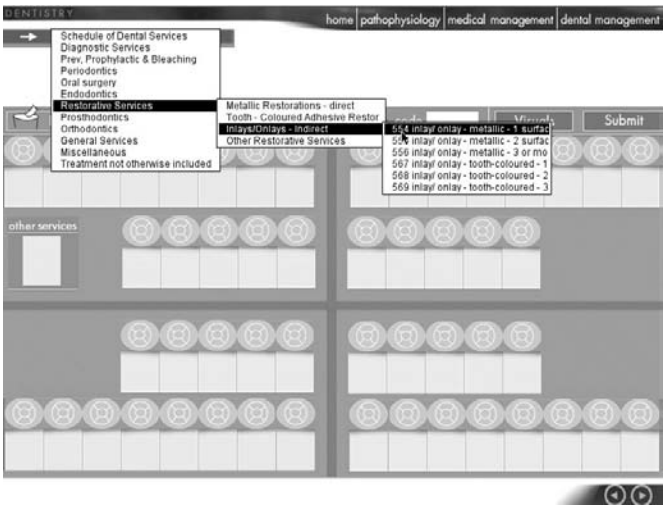

Figure 14. Expert answers for the diabetes treatment plan

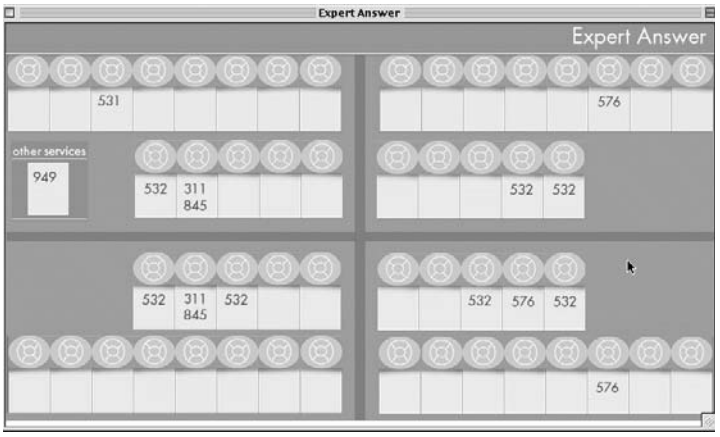

feedback. In addition, these typed responses can be saved by the student and referred to at a later point in their study. This approach was adopted to encourage students to engage with the content and synthesize ideas in their own words. Students are also encouraged to write their own notes and ideas in their personal notebook that can be printed or saved as a Microsoft Word file for review at a later point in the semester.

Authentic Activities can be Integrated and Applied Across Different Subject Areas and Lead Beyond Domain-Specific Outcomes

Students will be able to view the cervical screening cases from different perspectives. Medical students, nurses, and other health professionals should become aware of different disciplinary approaches and roles in cervical screening. Students

should begin to see the cervical screening process from the woman's perspective as opposed to the clinical perspective.

The case-based approach utilized in the virtual dental clinic allows students to examine a process for examining other similar cases in dentistry.

Authentic Activities are Seamlessly Integrated with Assessment

Young (1993) suggested that traditional forms of assessment in situated learning may prove to be inadequate. Authentic learning tasks must be assessed using methods that best align with the task. Within the virtual dental clinic, we attempted to do so by asking the students to develop a treatment plan using an electronic version of the protocols utilized in a traditional clinic. Our aim in developing this method of assessment was to foster higher-order thinking skills. We were also conscious of providing a method of formative assessment that allowed (Choi & Hannafin, 1995), "generation of ideas and the presentation of problem-solving processes such as planning, implementing, and revising" (p. 65). In order to simulate the use of the treatment chart, an electronic dental chart was created to allow users to create treatment plans. The electronic dental chart allows the trainee dentist to select a category of dental services and allocate a specific treatment for individual teeth. This chart also allows the user to complete cases and submit information to obtain expert feedback. The expert feedback provides precise information about the treatment protocol for each tooth. The students can compare their treatment plans to the experts' plans and then reenter the virtual clinic to rectify any inaccuracies and misconceptions. This concept of authentic assessment tasks is essential in the instructional design of authentic learning tasks. As stated in Young (1993), "Assessment should be a seamless, continuous part of the activity (a learning/assessment situation)" (p. 48). The final exam paper also mirrors the authentic learning task in the multimedia package by utilizing a case-based learning approach.

Although not a formal part of assessment, the SET module will be gradually utilized in all parts of the medical curriculum. Activities have been embedded that reflect real-world decisions and clinical encounters. Students will be given the opportunity to complete a number of on-screen sequencing and clinical interpretation tasks. To assess whether they are able to identify the barriers to cervical screening, they will be required to respond to a number of questions relating to the video sequence. Student assessment will be via the above self-assessment activities and tutor feedback during the tutorial setting. As the assessment is developed, we will utilize principles as outlined by Young (1993).

Authentic Activities Create Polished Products Valuable in Their Own Right rather than as Preparation for Something Else

Both modules are polished products in their own right, which focus on specific content relevant for treatment in dentistry and cervical screening. By studying each of the modules, the students will learn in-depth knowledge about the topic. Because the modules focus on a difficult content area, they act as stand-alone modules or complement other aspects of the curriculum. For instance, the SET module will be utilized to complement the existing forms of teaching cervical screening, which include face-to-face settings, video, pelvic models, observation, and clinical practice.

Authentic Activities allow Competing Solutions and Diversity of Outcome

The virtual dental clinic focuses on the examination of clinical information to develop a treatment protocol, whereas the SET module emphasizes communication, process, and procedures in relation to cervical screening. In examining the SET

module, students should be able to learn about communication practices that can be transferred to other clinical areas, particularly, of a medically sensitive nature. Students should be able to interpret content in a diversity of ways and begin to assimilate some of these concepts into their own process of completing cervical screening.

EVALUATION

An initial evaluation was undertaken to determine user perceptions in relation to the virtual dental clinic. Three practicing pediatric dentists participated in a focus group. A number of insights were gained into the design of the virtual clinic and its authenticity. We examined the match between the actual clinical setting and the virtual dental clinic. It appeared that presenting all relevant clinical information in one session may overwhelm the student:

If we think about the diabetes case and ... the virtual clinic, what do you think about that case in terms of how realistic it was…

It would be quite different. You would probably have more than one appointment and that was quite tricky deciding—on the first day I probably wouldn't do all these things. You could put them under general anaesthetic. Apart from that it was quite difficult if you had to write the whole lot out on the same day you would probably do something after the general anaesthetic get them back two weeks later and say okay, how's the toothbrush going.

Navigation also appeared to be an issue in the virtual clinic. We provided two methods of navigation. These included a site map and hotspots in the clinical setting. Although we provided a brief tutorial for the students, all three students still failed to utilize the hotspot information.

When I moved the mouse it came up and I didn't realise what I could click. I think if you want us to get the picture on the top of the menu, you should have it flashing or something like that. So that it shows up.

Further design work is being undertaken to address this misunderstanding. An animation will be utilized instead of the existing help screens to highlight relevant information in the virtual clinic. Our design attempted to provide an open exploration of the clinic. However, this proved too advanced for the users. Although we provided flexible access to the resources to solve the clinical case, the students still utilized the site map in a traditional top-to-bottom and left-to-right reading pattern as opposed to clicking on information that they considered relevant at that point in the case:

When you went into the office?
I went back to the menu and went to help. I couldn't understand. So then I went back to the other picture and found it by accident. I clicked on the telephone or something.

The sequence of information was also important to the user:

Did you actually read about the teacher; the specialist information?
Don't you think this information should go before the examination? You are talking about the medical history and social history. It should go before the examination.
If it was a referral, you would get a note from a doctor before she actually comes in, which gives you the whole..., and you don't have to look for anything.

Our goal of designing the module so that students would need to revisit some clinical information appeared to be successful in some instances:

Did you go back to the visuals when you were completing the treatment plan?
Did you need any other information at that point?
Patient file, complaints and history. I did use it, but I did go back to the pictures quite a lot. How many times? Three, five times. I think I wrote it down which made it a bit easier. I don't know the numbers so it made it a lot harder.

However, it appeared that the students had difficulty providing a treatment number from the electronic treatment plan as opposed to the usual paper-based booklet. It also appeared that obtaining expert feedback could have been optimized:

Did you all submit and get the expert answers? I didn't get the answers. I went to next. That's why I didn't find the expert…. Maybe it's a good thing to put the expert under next. Down the bottom. So you go to the next phase.

Further evaluation with a subsequent group should also inform the design and provide feedback to the development team. However, it appears that there is a fine line between authentic myth and reality.

Although the SET module has not been formally evaluated, our next step in the process is to complete extensive evaluation on the module from different perspectives. In the first instance, we will evaluate the module with clinicians experienced in the process. Some formative evaluation has already been undertaken with this group. In the second instance, a number of multimedia experts will be asked to evaluate the learning design of the module. Student evaluation will be undertaken over the next 12 months. We are also examining the evaluation of the module in cross-cultural settings to determine its applicability for different international usage. The module examined one woman's journey through the cervical screening process. In the future, we intend to examine modules for different ethnic groups.

Major Problems Encountered

The examination of the two modules within this chapter demonstrates a student-centered approach to their design. They represent rich teaching and learning resources that address conceptually difficult content areas. However, there are also cases of projects that have not been successful in developing viable educational resources. We cannot assume that design and development processes adopted by many development teams are sufficient to assure the success of a project. Burford and Cooper (2000) support this view and suggested that "most academics are not skilled in interface design, multimedia, selecting appropriate technologies for online teaching, nor project management" (p. 207). For this reason, they suggested that "whatever the developmental model, it must be achievable within the confines of established practice and available resources" (p. 209). However, it is important to remember that online and multimedia design and development are highly creative processes. Design and development models help to minimize potential difficulties in projects, but they never eliminate all constraining factors. According to Burford and Cooper (2000), "Whatever the model used, however well defined the process, the development process itself is a diffuse and difficult one. From its first conception to a final product, a development process is fraught with undefinable influences and unpredicted contributing factors" (p. 210). This section examines some of the consistent problems encountered in the transformation of a curriculum with multimedia and online learning:

- A consistent problem encountered in designing and developing multimedia modules is that academic staff members are over ambitious with their goals. Through a process of coaching and educating academic staff, it is possible to change this perception. Because it often requires 300–800 hours of development per course hour, multimedia should only be used for areas where it is

appropriate. The virtual dental clinic and the cervical screening module represent conceptually difficult content that warrant the above time and effort on the part of the development team. The first two questions we ask are as follows: Can this be completed using another teaching method? And why multimedia? Technology must enhance the teaching and learning process and should be used for addressing learning misconceptions and complex and difficult content that cannot be easily explained in another form.

- Another common problem is that many academic staff members apply their traditional teaching styles in designing and developing multimedia and online learning. Academic staff often focus on instructivist teaching models in developing their online or multimedia modules. The challenge in this situation is for the instructional designer to provide other pedagogical perspectives and suggest alternative approaches such as case-based reasoning, PBL, and authentic learning environments. There are a number of factors that need to be considered in this situation. For instance: What are the learning outcomes of the module? What pedagogical methods best suit the attainment of these outcomes? It is important to always take an eclectic approach to the teaching and learning process and suggest methods of teaching best suited to the entire learning context. There is a delicate balance between implementing the content expert's approach and coaching the academic in other pedagogical possibilities, which may enhance the learning of the content by the user.
- It is important not to underestimate the time required to design and develop online and multimedia products. As suggested by the above formulas, there must be an excellent pedagogical reason for justifying the resources required for multimedia and online learning.
- Working in teams is both a rewarding and challenging experience. It is important to employ a dedicated manager who can coach the design and development team in appropriate processes, and who has the ability to harness creative energy and deal with the inevitable tensions that arise in creative teams. By focusing on the goal as opposed to personal ownership, tensions can often be dissipated.

A potential bottleneck exists between the content expert and design and development staff (instructional designers, graphic designers, programmers, etc.) in terms of translating content into a form that embodies sound educational design. A process or strategy is required to streamline the interaction between the instructional designer and subject matter expert (Keppell, 2001). One of the most important principles in any project is to clarify the roles and expectations of the client/SME. Many projects fail due to an inappropriate consideration of what the client/SME expects from the project. According to Coscarelli and Stonewater (1979–1980), "An understanding of client psychological types and an ability to differentially respond to various types is a particularly effective designer strategy for relationship building and managing" (p. 16). It is therefore essential to establish a successful working relationship with an SME by determining philosophical assumptions of the SME before beginning the instructional design (Davies, 1975), as "a great deal of what is accomplished depends on the quality of the client–consultant relationship" (p. 351).

CONCLUSION

Learner-centered approaches emphasize problem-based and case-based learning, which attempt to create realistic learning interactions in order to replicate professional practice. The above discussion demonstrates how authentic

learning multimedia modules have been used to complement a medical, dental, and health science curricula. The learning design for each module is carefully articulated in order to provide an insight into the process of instructional design that can be transferred to other learning settings and other content areas. The articulation of the learning design also demonstrates the explicit instructional design decisions that were made in the two modules, each of which are based on a constructivist teaching and learning model. It is also suggested that interactive, media-rich multimedia modules are relevant for difficult content areas or areas where misconceptions may be prevalent in the curriculum. The articulation of this model of teaching and learning allows other designers and researchers to examine the applicability of these designs for their own setting and circumstances.

ACKNOWLEDGMENT

The author wishes to acknowledge the graphic designers on both projects: Jennifer Kirk, Avril Martinelli, Jacqui Jewell, Andrew Bonollo, and Carolyn Casey from the Biomedical Multimedia Unit.

ABSTRACT

E-learning plays a key enabling role in knowledge management for individuals, schools, and enterprises. Nevertheless, the lack of standards in content and learning management systems (LMSs) makes the reusability and interoperability of learning resources infeasible. The emergence of the SCORM specification has shed light on the standardization of e-learning. Unfortunately, the existing SCORM-compliant asset model is simplified; only a few asset types are allowed. On the other hand, W3C's declarative-style SMIL (Synchronized Multimedia Integration Language) is becoming prevalent in designing Web-based instructions with the consideration of temporality and spatiality of presentations. In addition, advances in real-time multimedia technologies can vitalize further these instructions. In this study, we propose an SMIL-enabled asset model with the enhancement of multimedia streaming. To render SCORM-compliant SMIL-enabled streaming contents, a Java applet-based SMIL RTP/RTSP LMS system is designed. We develop the proposed system in the Java EJB environment to tackle the issue of platform interoperability. The

resulting system demonstrates an encouraging direction towards a more vivid and interactive SCORM-compliant e-learning.

INTRODUCTION

The rapid expansion of the Internet has had a dramatic impact on both our lives and our education. The major feature that differentiates e-learning from traditional learning is its ability to train anyone, anytime, and anywhere, which is attributed to the openness of the Internet. Without temporal and spatial limitations, a person can have an independent and individual learning space. Universities first realized the advantages of e-learning and actively built up the so-called cyber universities that offered diverse asynchronous or synchronous distance learning in regular, professional, and/or continued educations. Next, business companies also recognized the significant market benefits of e-learning. Analysts predicted that corporate spending on e-learning programs would reach US $23 billion by 2004. Yet, some innovative enterprises have moved beyond training to focus on e-learning in the context of knowledge management and found that e-learning is a vital step in the development of knowledge management systems (Ismail, 2002).

The major feature of e-learning is digitalized courseware, which is managed by the so-called Learning Management System (LMS). In addition, LMS helps learners to learn the coursewares and keep track of their learning behaviors. But coursewares in different LMS platforms cannot be interoperable directly, so the attempt to share learning resources is impeded. The most critical issue for this is whether the process of designing the coursewares follows some kind of standards. Besides, the heterogeneity existing in the different LMSs is another impediment. There is no way to monitor and evaluate the learner's behavior from one platform to another. All these hinder the sharing of learning resources, including platforms and contents. Although it has been recognized that developing reusable and sharable content objects is of great importance (Anido et al., 2001a, 2001b; Muzio et al., 2002; Rifon et al., 2001), not all of the aforementioned issues have been addressed. To overcome these hurdles, a variety of e-learning standards have been developed, such as IMS, IEEE LTSC, AICC CMI, LMML, ARIADNE, and ULF, and so forth. Recently, Advanced Distributed Learning (ADL) organization, supported by the U.S. Department of Defense, and major e-learning vendors, established one specification called Sharable Content Object Reference Model (SCORM) toward standardizing e-learning (SCORM, 2003). SCORM integrates and refers to the aforesaid standards from AICC, IMS, IEEE, and several e-learning factories. The objective of the specification is to facilitate the interoperability between SCORM-compliant contents and SCORM-compliant LMS, and to make the valuable resources become durable, interoperable, accessible, and reusable.

On the other hand, recent progress in multimedia technologies is greatly changing people's life styles. The marriage of the Web and multimedia technologies results in the Web-based multimedia presentations, so people can read multimedia lectures via general browsers. However, designing multimedia presentations is not a trivial task. Synchronized Multimedia Integration Language (SMIL) (SMIL, 2004) built on XML and proposed by W3C, provides a simple way to design multimedia presentations in a manner similar to HTML documents. The SMIL specification meets three requirements of multimedia document models: temporal, spatial, and interaction.

Furthermore, the demand for real-time and robust multimedia applications is rising dramatically, as Internet connection speeds improve. Various protocols for supporting networked multimedia services have been proposed. Two of the representatives are Real-Time Transport Protocol (RTP) and Real-Time Streaming Protocol (RTSP). RTP is designed specifically to transmit real-time

media data and enables client applications to play media over the Internet without having to download the entire file at once. RTSP, a state-oriented protocol, provides VCR-like functionality to allow more interaction between users and media sources.

Multimedia presentations can attract learners' attentions because of the vivid video images and sound effects. According to the SCORM specification, multimedia materials, such as images, are defined as *assets* in the content. Currently, however, the samples in this specification or mostly SCORM-complaint LMSs that only handle simple assets like pictures. To vitalize the asset contents of SCORM, this study designs a new asset model based on SMIL and RTP/RTSP standards, so that the features of spatiality, temporality, interaction, and streaming control can be added into assets. The extended asset model conforms to SCORM, and, thus, any SMIL-enabled asset can be imported to LMS, and communicates with LMS to track the learners' learning progresses.

In addition to facilitating the interoperability of sharable course contents, there is a great necessity for making LMS interoperable. The prototype of ADL sample LMS 1.2 environment is oversimplified and cannot fit the requirement of interoperability and reusability. On the other hand, component-based computing has been recognized as a successful paradigm that allows two or more software components to cooperate in a seamless manner, despite heterogeneities in implementation of languages, service interfaces, and deployment platforms (Li, 2002). Therefore, we choose the emerging Enterprise Java Bean (EJB), a distributed component-based computing environment, to develop the proposed LMS for realizing SCORM-compliant SMIL-enabled multimedia streaming contents.

This paper is organized as follows. First, it gives a brief review about e-learning standards. Then, we propose the SMIL-enabled asset model with multimedia-streaming functionality and show how SMIL documents can be wrapped as SCORM assets in the manifest and the structure of SMIL documents. The next section discusses the rendering of SMIL-enabled assets by a Java applet-based SMIL player. Then comes the design of SCORM-compliant LMS in the EJB environment, and after that, a content sample and its presentation on a Web browser are demonstrated. Finally, we conclude this paper by providing some directions about future work.

STANDARDS IN E-LEARNING

In this section, we briefly review several popular standards in e-learning.

Existing Standards

Instructional Management System (IMS) (AICC, 2003; IMS, 2003) is a global learning consortium to develop an open specification for sharing of heterogeneous platforms, reusability of valuable contents, tracking of learned material, exchange of records, and so forth. IMS is the generator of Learning Object Metadata (LOM), which is extended continually to IEEE LTSC. IMS submits suggestions and maps the metadata concept in the so-called content aggregation model (CAM) to IEEE LTSC. Metadata provides a shortcut for content developers to search and retrieve desired contents in the content repository. IMS defines nine basic categories of metadata: general, life-cycle, meta-metadata, technical, educational, rights, relation, annotation, and classification. In addition, IMS introduces the package type of instruction: content packaging. By assembling all physical files and describing the organizations and relations of the content items in a manifest file, a content package is flexible to be assembled, disassembled, merged, and recreated from contents. However, IMS tends to concentrate on the conceptual layers, and lacks the details of implementation.

Learning Technology Standards Committee (IEEE LTSC) (LTSC, 2004) has devoted itself to the tutorial standards of software, tools, development, maintainability, and contents. There are many teams in LTSC, of which the LOM team is responsible for developing the contents' standards. The main target of LOM is to facilitate the sharing and exchange of contents by defining plenteous metadata in LOM.

Computer Management Instruction (CMI) in Aviation Industry Computer-Based Training Committee (AICC) (AICC, 2003) defines the way to construct a course. In addition, CMI provides a data model to define the mechanism of communications in LMS, the status of instruction resources, and the tracking of learners' behaviors. However, from the viewpoint of the data model, CMI lacks the course structure, metadata, and content packaging.

Learning Material Markup Language (LMML) (LMML, 2004) was developed by Passau University in Germany. LMML, an XML-based language, is used in describing course contents; however, it is difficult to add a low-level media and, thus, results in the lack of clear hierarchy.

Alliance of Remote Instructional Authoring and Distributed Networks for Europe (ARIADNE) (ARIADNE, 2004) is the alliance of many universities in different European countries. ARIADNE emphasizes the integration in multi-languages and multi-culture. It generally follows the LOM specification but with minor simplification.

Universal Learning Format (ULF) (ULF, 2002), which originated from XML and RDF, defines content types from a series of learning systems by SABA Inc. It provides a complete specification of description and bridges other standards, such as IMS, ADL, IEEE LTSC, and so forth.

SCORM

Sharable Content Object Reference Model (SCORM) adopts the concepts of metadata and content packaging from IMS and IEEE LTSC to define a standard set of metadata element definitions that can be used to describe learning resources. SCORM Version 1.2, announced by ADL, is composed mainly of Content Aggregation Model (CAM) and Run-Time Environment (RTE). CAM focuses on how to construct reusable and sharable contents, whereas RTE ensures the interoperability of different LMSs.

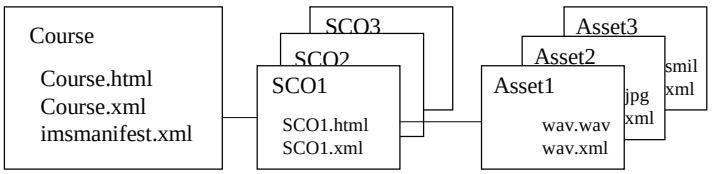
Content packaging defines the structure and the intended behavior of a collection of learning resources. It is used to provide a standardized way to exchange digital learning resources among different systems or tools. A package uses a manifest file that contains the following information for describing the package:

- meta-data about the package
- an optional organization section that defines content structure and behavior
- a list of references to the resources in the package

In a content package, the organizations component defines the structure of the content, and the resources component describes external resources as well as the physical files of which the package consists. The resources are referred to at various points within the organization component. The type of the SCORM resource is defined by the attribute, named "adlcp:scormtype". The value of the "adlcp:scormtype" is either "asset" or "sco".

An asset is an electronic representation of media, text, image, sound, Web page, assessment objects, or other pieces of data deliverable to Web clients. Learning contents normally are composed of assets. On the other hand, a Sharable Content Object (SCO) contains a collection of one or more assets that include a specific launchable asset utilizing a SCORM RTE to communicate with LMS. A SCO represents the lowest level of granularity of learning resources that can be tracked by an LMS in a SCORM RTE. Figure 1

Figure 1. Concept diagram of SCORM course content



shows the concept diagram of a SCORM course content. Each course is composed of several SCOs, which, in turn, are constituents of several assets. The structure of the course content is defined in imsmanifest.xml_whereas the metadata of each learning resources is described by the corresponding XML files.

The purpose of SCORM RTE is to provide a means for interoperability between SCO-based learning contents and the learning management systems. An essential requirement of SCORM is that learning contents should be interoperable across multiple LMSs, regardless of the tools used to create them. For this to be possible, there must be a common way to start the content and a common way for the content to communicate with an LMS and predefined data elements that are exchanged between an LMS and the content during its execution. The three components of the RTE are defined in SCORM as Launch, Application Program Interface (API), and Data Model.

SMIL

SMIL provides a simple way to design TV-like multimedia presentations on the Web (SMIL, 2004). The SMIL syntax conforms to the XML standard, so one can write SMIL presentations using general text editors. There are several salient features that make SMIL attractive in designing Web-based multimedia presentations.

- The presentation designer can indicate the spatial layout and temporal relationships of media objects.
- Media objects can be distributed either from the same resource of the SMIL document or any place specified by the URL.
- It supports the functionality of hyperlinks.
- Media objects can be presented on a client's browser according to system and personal preferences, such as network bandwidth, user language, and screen resolution.

An SMIL presentation usually is rendered by a specific player, such as RealPlayer. Unfortunately, most Web browsers, including Microsoft Internet Explorer 6.0 and Netscape, do not support SMIL documents yet. The rendering work involves pre-fetching and buffering media objects. To accommodate the requirement of SCORM, we extend our previous work on SMIL players (Li & Chen, 2001) and propose a Java applet-based architecture for rendering SMIL-enabled assets on IE in this study.

Multimedia Streaming

RTP, defined in IETF RFC 1889, is a transport protocol for delivering real-time multimedia streams over multicast or unicast IP networks. RTP usually is carried by UDP in order to efficiently transmit data under time constraints; thus, neither resource reservation nor QoS is guaranteed. A number of fields are defined in the RTP header to specify what actions should be taken for a receiver when packets arrive. For example, the field *payload type* indicates the media type and the packet's compression way, such as audio or video

encoding. The fields *time stamp* and *sequence number* are used by the receiver to synchronize time-based media packets. RTP is accompanied with Real-time Control Protocol (RTCP), which periodically sends information about the quality of the packet transmission to all participants in the RTP session.

RTSP, initiated by Netscape, RealNetworks, and Columbia University, is an application-level protocol for controlling single or multiple real-time streams, such as video or audio delivered over the Internet (Muzio et al., 2002). Similar to HTTP, RTSP uses textual commands to control stream transmission. However, unlike HTTP, RTSP is a state-oriented protocol, by which an RTSP server and client need to maintain the state of the connection session labeled by a session identifier. It offers the functionality of VCR-like remote control so that the client may fast-forward, rewind, pause, or stop the media streams. Furthermore, in contrast to HTTP, both server and client can issue requests. For instance, the server may ask the client to connect to another media server for services. RTSP request/response messages in a session often are transmitted in a transport-level (either TCP or UDP) channel independent of the media channel. The underlying transport standards for an RTSP session to deliver media streams can be various, ranging from TCP, UDP, multicast UDP, or RTP.

SMIL-ENABLED MULTIMEDIA-STREAMING ASSETS

In SCORM, the mechanism of content packaging is designed for packing instruction contents and the navigation sequences. In each content package, the oranizations portion specifies the content structure and the behaviors of this content. The resources session describes the instruction materials needed in this content, the type and physical location of each physical file. To create an SMIL-enabled asset, one may define an unlaunchable asset, which refers to a physical filename ending with .smil (e.g., "intro.smil", as shown in Figure 2 and Table 1). In addition, a <metadata> element can be used to describe its attributes. The instruction unit specified in the package is composed of one SCO:R_S1, which, in turn, consists of five assets as R_L1, R_U1, R_U2, R_U3, and R_U4. In this case, the instruction is packed in the content package, named "MMC.pif", and the content of imsmanifest.xml in "MMC.pif" is shown in Table 1.

The intro.smil document defines the rendering sequence of text (para.txt), image (2122.gif), sound (s1.wav) objects and real-time media (in intro.smil) synchronously in different regions, respectively (see Table 2).

The physical resource for SCO R_S1 is the file SCO.html, which is shown in Table 3. It consists of two javascript files packed in the content package. This SCO communicates with LMS by invoking some functions like doLMSGetValue, and all functions called by SCO.html are defined in either APIWrapper.js or AUFunctions.js.

After importing the content, LMS will identify each element in the content package and place them in the appropriate positions in order to show them when learners launch this content through the runtime environment. Figure 3 illustrates how the content package is composed, the process of launching contents, and the communication with the LMS server and the RTP/RTSP server.

Each SCO must contain at least, one launchable asset (e.g., R_L1 in Table 1) that contains javascript files and is responsible for communicating with LMS. When the SCO communicates with LMS, the launchable asset is connected to APIAdapterApplet, which, in turn, communicates with LMS afterward. LMS invokes EJB objects, residing in the server, to access LMS DB with the data model that stores the information of SCOs tracked by different LMSs.

The SMIL document can be defined as an unlaunchable asset similar to the jpeg asset when a content package is compiled. Since an SMIL

document may be composed of several files, all files in the SMIL document must be packed as resources in the content package (see Table 1). Moreover, an SMIL document may contain real-time multimedia objects that refer to an RTP server. The RTP server sends a stream of bytes containing the media back to the client. The SMILAppletAdapter buffers a portion of

the media, which the client begins playing after a certain portion has been received. Additional media are continually buffered, providing users with an uninterrupted clip.

RENDERING OF SMIL-ENABLED MULTIMEDIA-STREAMING ASSETS

Since most Web browsers do not support the functionality of rendering SMIL documents, we develop a Java applet-based player by extending the SMIL player presented in Li and Chen (2001). The applet specification is embedded in the content, as shown in Table 4. When the instruction content is presented to a learner, the player automatically will be downloaded and installed onto the client's browser and the SMIL document rendered at the same time.

The SMIL player is built upon Java Media Framework (JMF) and Java-XML technologies to overcome the issues of interoperability and

</body>
</smil>
```

dates the specified SMIL document and retrieves the embedded elements and attributes. Protocol Handler invokes the procedures for handling specific protocols, such as HTTP/HTML, JPEG, WAV, and RTP media. Finally, Render Engine is responsible for the appropriate rendering of different media objects.

Since the SMIL-type resource is not supported by most LMSs, the approach of the applet-based player provides a lightweight, feasible solution for augmenting the functionality of LMSs. If the SMIL standard were eventually adopted by the SCORM society, the player could be embedded into APIAdapterApplet of LMS; this definitely will simplify the development task of SCORM contents.

SCORM-COMPLIANT LMS IN EJB

To tackle the interoperability issue of e-learning platforms, we developed the proposed SCORM-compliant SMIL-enabled multimedia streaming LMS on Java Enterprise Java Beans (EJB) environment (Jboss, 2003). The EJB environment, part of Java 2 Enterprise Edition (J2EE), is a technology for developing, assembling, deploying, and managing distributed component applications. It simplifies the handling of issues inherent in distributed applications by concealing such complexities as security, transaction handling, and database access, and enables component developers to focus on business logic. There are two types of enterprise Java beans: session and entity. Session beans are business objects designed to act as the interface between business logic and application logic, whereas entity beans are data objects. In the study, the session bean calls out to a single underlying entity bean to access the database model. The mechanisms of EJB, such as business objects, data objects, object pool, and transaction, are particularly suitable for developing the data model in SCORM RTE.

```

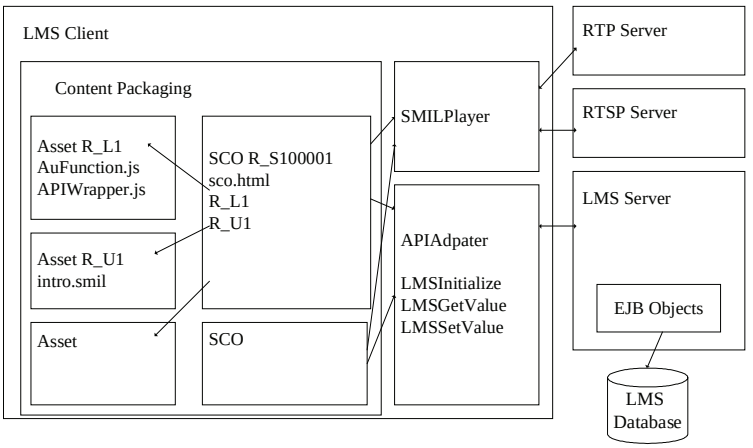
Figure 3. The act of Content content Packaging packaging in LMS Clientclient



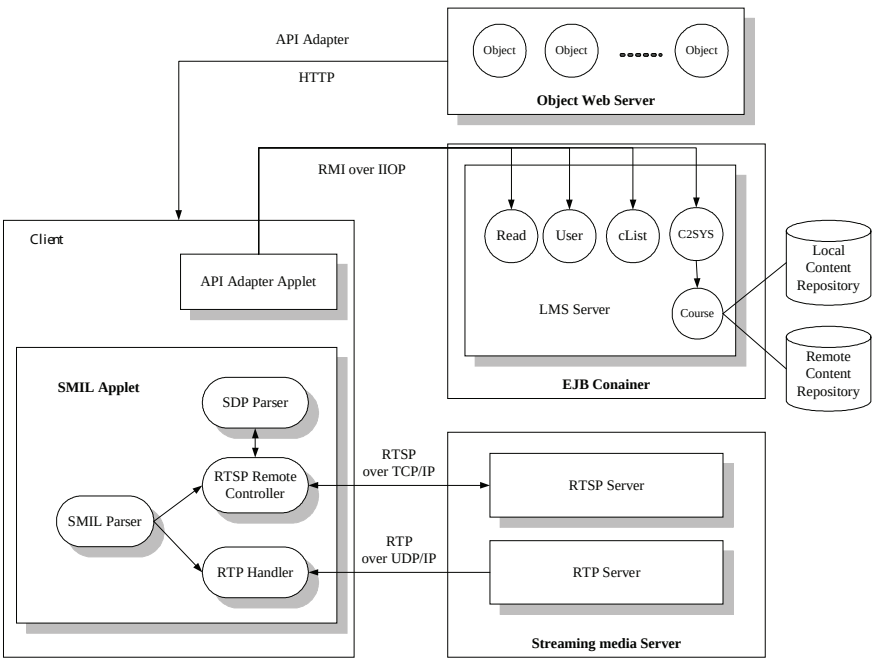
System Architecture

Figure 4 shows the system architecture of the proposed LMS developed in the EJB environment. First, the client has to download an API Adapter Applet from the_Object Web Server. An API Adapter Applet is an EJB client that is responsible for communicating with the LMS Server, so that a client can assess learning material in LMS. The LMS Server follows EJB's model, and there are five enterprise Java beans in LMS Server, which are discussed as follows.

Table 4. The specification of an applet-based SMIL player in the content:sco.html

```
<applet archive="sSmil.jar" code="SmilApplet.class"
 width=450 height=380>
   <PARAM NAME ="location" VALUE="./smil-intro/intro.smil">
   <PARAM NAME ="height"   VALUE="380" >
   <PARAM NAME ="width"    VALUE="450" >
</applet>
```

Figure 4. The architecture of the proposed LMS in EJB environment

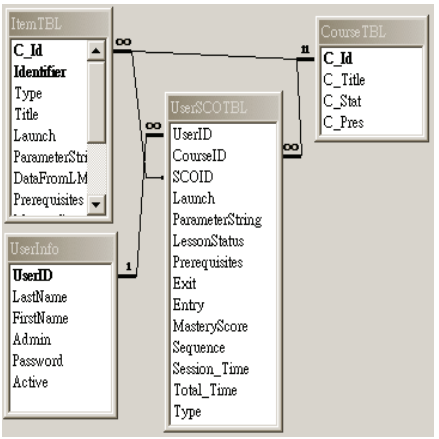


- **UserEJB:** UserEJB is an entity bean, that is in charge of confirming the legality of users and maintaining their information.
- **cListEJB:** cListEJB is an entity bean, that maintains the list of instructions available in LMS so that students can register as regular students or guests and choose any course they like to browse.
- **ReadEJB:** ReadEJB is an entity bean. The learning path of each student will be recorded in the LMS Server, if an instructor wants to keep track. When students are reading, taking tests, or setting preferences in an instruction, the ReadEJB bean will track and record such behavior in the data model defined in SCORM's RTE in the background. This bean plays the most important role in the proposed LMS.
- **C2SYSEJB:** C2SYSEJB is a session bean that allows teachers or system administrators to import courses or update course contents. In detail, this EJB object is responsible for unzipping the content package (a PIF file) of instructions, analyzing the MANIFEST, and allocating all physical files in appropriate locations in a content repository. Moreover, this session bean is the interface between EJB client and CourseEJB.

- **CourseEJB:** CourseEJB is an entity bean that endorses the C2SYSEJB bean to access the database of content repository. In implementation, this entity bean is wrapped by CourseEJB in a session bean, so one can access all business functionality without the overhead of polling the entity bean.

In order to support manipulating multimedia streams, the SMIL Parser parses SMIL-enabled assets and extracts embedded multimedia objects.

Figure 5. The entity-relationship of the LMS database



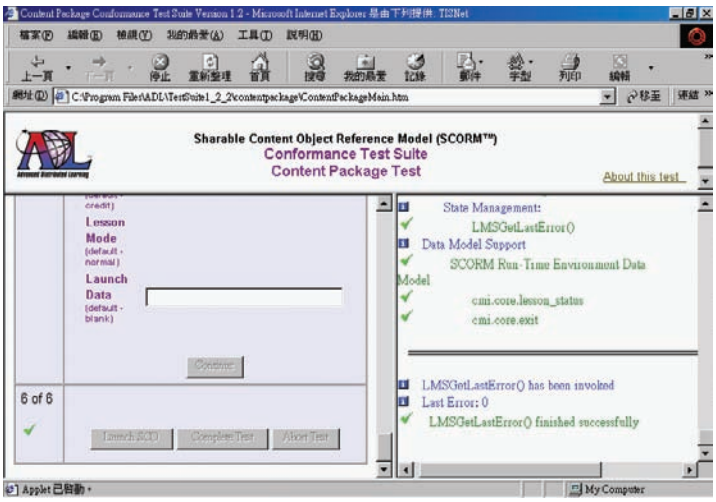
If the extracted object is an RTP object, the RTP Handler will be invoked to receive RTP media streams, synchronize audio and video stream, and render them in the client screen. On the other hand, when the client obtains an RTSP object, an RTSP Remote Controller also is called. Initially, the RTSP Server returns a Session Description Protocol (SDP) message, which describes the information of the RTP media to be transmitted. After parsing the SDP data by SDP Parser, RTP Handler receives and consumes the RTP streams. During playback, the RTSP Remote Controller handles the RTSP protocol between client and the RTSP Server, so that the client may issue play, pause, fast forward, rewind, or stop commands to control the streams.

Schema of Database

The database in the LMS Server is the place to store all detailed data, such as the individual information, specifications of instructions, learning paths, and so forth. The main schema of the database is depicted in Figure 5.

There are four major tables defined in the database. First, table UserInfo collects all the individual information. Specifications of each instruction are maintained in CourseTBL as an

Figure 6. Test SMIL-enabled content with Test Suite



unit. ItemTBL stores the detailed information on every learning resource, such as asset, SCO, and aggregation. Finally, UserSCOTBL stores the students' learning behaviors, such as student name, score.max, core.exit, and so forth. All fields are designed adhering to the data model in SCORM RTE. From the schema, one notes that fields and relations are designed according to attributes of objects and roles of objects in LMS, respectively.

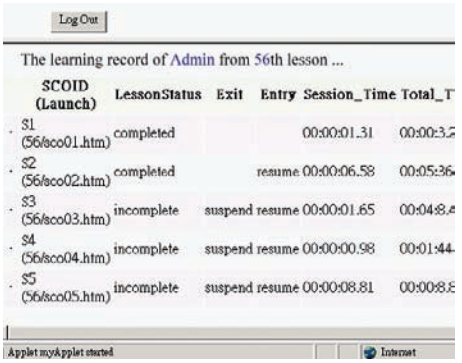
Figure 9. The presentation of the RTSP in SMIL-enabled SCORM content on learner's browser

Figure 10. The learning path tracked



EXPERIMENT AND DEMONSTRATIONS

The proposed SMIL-enabled multimedia streaming e-learning system has been experimented on JBoss-3.0.3_Tomcat-4.1.12 EJB server (Jboss, 2003). To demonstrate the effectiveness of the system, the SMIL-enabled SCORM content package (shown in Table 1) is imported to the proposed LMS, but only after the conformity with the SCORM standard of SMIL-enabled content is validated. SCORM Version 1.2 Conformance Test Suite Version 1.2.2 provides a simple tool for self-testing. The test suite provides conformance test from four options:

- LMS Run-Time Environment Conformance Test
- SCO Run-Time Environment Conformance Test
- Meta-Data Conformance Test
- Content Package Conformance Test

Figure 6 shows the steps of the successful tests of the proposed SMIL-enabled instructions

against the conformances of SCO Run-Time Environment, Meta-Data, and Content Package.

Subsequently, the content can be imported to the LMS server, as depicted in Figure 7. We choose the type of navigation control as *choice*, and this finishes the registration procedure. Figure 8 is the snapshot of browsing SMIL-enabled RTP content, and Figure 9 illustrates an RTSP multimedia object instead. The tiny difference between the two snapshots is that there is a VCR-like control bar below the movie in Figure 9.

From the snapshots demonstrated, SMIL instructions are rendered on the learner's browser appropriately, whenever the instructions contain raw media, such as sounds, graphs, texts, and so forth, or the read-time types RTP/RTSP. One notes that the tree structure of the course content is listed clearly in the left-down frame as well, and learning can proceed on the learner's demand. Figure 10 illustrates the learning path of some students recorded by ReadEJB. With this functionality, the teacher is granted the ability to monitor or query the learning path and the students' progress in the course, and thus, appropriate measures can be taken to improve the instruction quality.

CONCLUSION AND FUTURE WORK

This paper proposes an SMIL-enabled asset model that allows W3C's SMIL documents to be embedded in the instructions. The asset model is enhanced further by incorporating multimedia streaming objects. Realizing and rendering such assets on learners' Web browsers, a Java applet-based SMIL player and LMS are needed. To meet the reusability of software development, we integrate the components of the player developed in our previous work, SAX for parsing SMIL documents and JMF for playing the RTP/RTSP media. To handle the interoperability issue of LMS, we developed the proposed LMS in the overwhelming Java EJB component-based computing environment. The initial experimental results show an encouraging achievement. With SMIL ability and streaming multimedia objects of assets, instruction contents could be more vivid and interactive. The proposed asset model is adherent to the SCORM standard; thus, it can be sharable, reusable, accessible, and durable. As far as the references surveyed, our work presented is the very pioneering study in the literature toward integrating SCORM, SMIL, and multimedia streaming in e-learning. Based on the lessons learned in this study, the next research direction is to enhance the proposed LMS by incorporating directory services, such as Lightweight Directory Access Protocol (LDP), so that remote SMIL-enabled assets can be interoperable and sharable. Another objective could be aimed toward developing an efficient and effective way of maintaining these assets using ontology engineering for supporting resource and knowledge sharing.

Chapter 2.7
Feature-Based Multimedia Semantics:
Representation for Instructional Multimedia Design

Michael May
LearningLab DTU, Technical University of Denmark, Denmark

ABSTRACT

The aim of this chapter is to sketch a semantic taxonomy of representational forms (or "sign types" in the terminology of semiotics) relevant for the compositional analysis, design, and indexing of multimodal multimedia, specifically, in the domain of instructional design of learning objects, and to contribute to current attempts to bridge the "semantic gap" between the technical and spatio-temporal description of media objects and the contextual perception and interpretation by users of their content.

INTRODUCTION

In the present chapter, it is suggested that descriptions of *graphical and multimedia content*, as it is known from multimedia databases, multimedia programming, and graphic design, should be extended to include *taxonomic information about the representational forms* (or "sign types" in the terminology of semiotics) combined in multimedia presentations.

From the point of view of design, there is a fundamental *rhetorical* problem in deciding which *combination of media types and representational forms* ("sign types", "modalities of expression") would be adequate for a particular multimedia presentation within a particular context-of-use. This rhetorical problem is necessarily present in all forms of information, interface, and interaction design, although it is not the whole story of designing usable and adequate presentations, since there are many criteria of usability as well as adequacy of presentations (i.e., presentations that are relevant, intelligible, efficient, consistent, aesthetic, etc.) and many levels of design that have to be considered in the design or automated gen-

eration of presentations (functional specification, spatial layout, temporal organisation, forms of interaction, forms of cognitive support for users, contextual relations to activities and situations of use, etc.). In this chapter, we will only address the rhetorical problem of "media and modality" and specifically the problem of taxonomy, that is, the need for some kind of classification of media types and representational forms to support a conceptual understanding of the design space of available types and its operational specification in particular design contexts (where the example given here is multimedia content specification for instructional design).

TAXONOMIES OF MEDIA AND REPRESENTATIONAL FORMS

Taxonomies in Graphic Design

One might think that taxonomic issues in graphic design have been settled for a long time, since the representation and layout of simple graphical objects like two-dimensional documents with "text" and "illustrations" appear simple compared to the full complexity of computer-based animation, video, gesture, and haptics. This appearance of simplicity is an illusion, however, and the problems of representation and layout of multimodal documents have not yet been fully solved (Bateman, Delin, & Henschel, 2002; Bateman, Kamps, Kleinz, & Reichenberger, 2001). It is important, from the point of view presented in the present chapter, to note that *multimedia* communication as well as *multimodality* (of representations) does not originate with modern computer technology or electronic audio-visual technologies like television. We know multimodal representations from the printed graphical media in the form of combinations of language, images, and diagrams, and before the invention of printing, from combinations of writing and drawing within the graphical media. The fundamental origin of multimedia communication and multimodality, however, is coextensive with the origin of language, since the embodied language of human speech combining multiple media (speech, gestures) and multiple forms of representation (natural language discourse, intonation patterns, schematic "conversational gestures", facial expression, etc.) is an advanced form of multimodal communication (Quek, McNeil, Bryll, Duncan, Ma, Kirbas, McCullough, & Ansari, 2002) that in some ways can play the role of a natural ideal for designed technically-mediated communication.

The taxonomic problem of identifying and combining different types of media and representational forms (or "modalities") have been addressed in design theories based on the printed graphical media, but it was intensified with the advent of computer-based multimedia systems. It will be useful to start the present analysis of problems of taxonomy with a few early attempts to classify graphical objects.

With a few exceptions, the focus on taxonomic issues within *graphical design* has been on representational forms derived from examples of "business graphics", and it has been restricted to static graphical media objects. In the *scientific visualisation* community, on the other hand, there has also been some interest in taxonomic issues, but with a focus on images, maps, and graphs used for data visualisation within simulations and other forms of dynamic graphics. Early work in scientific visualisation was driven by presentations of examples of new applications and graphic algorithms, whereas the conceptual foundation of the domain was neglected. Recent work in the domain of *information visualisation*, common to business graphics and scientific visualisation, has attempted to present the area as based on knowledge of perception (Ware, 2000). This is an important step forward, but what is still missing is an understanding of the syntactic and semantic features of graphical expressions, and how these features are expressed in other media (acoustic, haptic, gestic).

With the increasing importance of the Internet and Web-based presentations, a new quest for taxonomies has arisen in studies of automated presentation agents and multimodal document design. It appears that, even from the point of view of document design restricted to static two-dimensional documents including text, pictures, and diagrams, there is still no consensus on a systematic description of multimodal documents (Bateman, Delin, & Henschel, 2002).

A taxonomy of graphics in design was proposed by Michael Twyman (1979). "Graphical languages" is here analysed along two dimensions: *configuration* and *mode of symbolisation*. The focus of Twyman was on static graphics and the role of eye movements in reading graphics. Configuration thus refers to different forms of linear, branched, matrix-like, or non-linear reading of graphical forms, whereas the "mode of symbolisation" refers to the verbal/numerical, verbal and pictorial, pure pictorial, or schematic organisation of the content. Ordinary text is usually configured typographically to be read in a linear fashion, whereas diagrams with branching nodes have a branching linear configuration, and pictures are examined in a non-linear fashion. Although we are presented with a classification of the "modes of symbolisation", there is no analysis of the semantic content as such. The classification is inconsistent in considering combined forms such as "verbal and pictorial" to be a class next to simple forms such as "pictorial" from which it must be derived. Twyman refers to the distinction between symbolic and iconic in semiotics, but does not find it relevant for the classification, and he does not utilise his own conception of "graphical languages". Even though the concept of a language implies syntactic and semantic structures, he only considers "pictorial" and "verbal" forms as aggregated and unanalysed wholes.

Another example of classification problems with "graphics" is seen in the work of Lohse, Walker, Biolsi, and Rueter (1991) and Lohse, Biolsi, Walker, and Rueter (1994). The methodology is here quite different; through a cluster analysis of individual subjective classifications of a series of examples of graphics, they arrive at the following distinctions: graphs and tables, network charts, diagrams, maps, and icons. The authors try to interpret these classes along two dimensions, but they are given no real analysis. The five classes seem to range from symbolic (graphs and tables) to more "analogue" forms (maps and diagrams) in one dimension, and from explicit and "expanded" forms of expression (network charts) to more implicit and "condensed" forms of expression (icons) in another.

The work of Lohse, Walker, et al. (1991) and Lohse, Biolsi, et al. (1994) should be understood as referring to "folk taxonomies" derived from clustering of perceived differences among representations. This kind of taxonomy could be important for studies of individual styles of reasoning and self-generated external representations (Cox, 1999), but less important for systematic models of design choices in multimedia design. "Perceived differences" will reflect peoples' attitudes towards representations rather than their intrinsic characteristics, and folk taxonomies are not consistent classifications: Sometimes people will group representations together because they have the same use context, sometimes because they are expressed in the same media, and sometimes because they "look alike" (but disregarding their semantic and syntactic properties).

Web-based techniques for presentation based on HTML and XML have enforced a clearer separation of document content from its layout as well as from different types of meta-data associated with documents, and this is reflected in recent theories of the structure and layout of multimodal documents. According to Bateman, Delin, and Henschel (2002) and Bateman, Kamps, Kleinz, and Reichenberger (2001), it will be necessary to distinguish five types of document structure: the *content structure* of the information communicated in a document, the *rhetorical structure* of the relations between content elements, the

layout structure of the presented document, the *navigation structure* of the supported ways in which the document can be accessed, and the *linguistic structure* of the language used to present the document. The question of media types is *implicit* in this typology since only graphical media documents are considered in these typographic theories, whereas the question of representational forms (or "sign types") is hidden in what is called "the linguistic structure". For our purpose, the linguistic structure should be generalised to the *semiotic structure* of multimodal multimedia documents or "objects".

Media Types

In early approaches to multimedia the concept of "multimodality" was constructed from an engineering point of view as referring to combinations of technologies. According to Gourdol, Nigay, Salber, and Coutaz (1992) and Nigay and Coutaz (1993), for example, a modality is associated with a physical hardware device. A multimodal system is accordingly defined as a particular configuration of hardware, that is, as a system that supports many "modalities" for input and output. The taxonomy that can be constructed from this point of view will be restricted to dimensions of the technical control of hardware systems such as the support given by these modalities with respect to temporal execution (sequential or parallel) and the combined or independent nature of commands with regard to the modalities. This taxonomy of "systems" does not consider the representational issues involved in multimedia, but from the perspective of users of applied multimedia systems, the important design decisions cannot be based on a characterisation of the physical devices and media, since it is precisely the representational and cognitive properties of the application that will determine what kind of support users can expect in their situated activity involving the application. An example is instructional design of multimedia applications for higher learning, where Recker, Ram, Shikano, and Stasko (1995) have stated the importance of what they call the "cognitive media types": Design of hypermedia and multimedia for learning should not be based directly on properties of the physical media, but on properties of the information presentation that are "cognitively relevant" to the learning objectives.

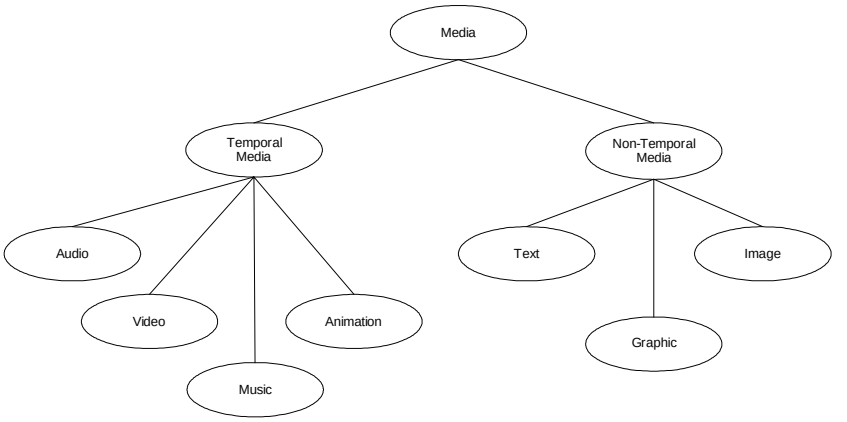
An important step forward towards a classification of media types was taken with the object-oriented approach to multimedia programming, but even with the focus on a conceptual foundation for multimedia (Gibbs & Tsichritzis, 1995), the software abstractions constructed to represent media types were mainly a reflection of the data types and digital file formats available at the time. The concept of media type introduced the idea of a template for distinguishing the representational from the operational aspects. With a template like

```
Media type <name>
    Representation
            <aspects of representation>
    Operations
            <categories of operation>
```

Gibbs and Tsichritzis (1995) identified a set of important media types as well as their associated forms of representation and supported operations. The actual classification of media types represented by media classes was, however, both incomplete and inconsistent.

The suggested media types are incomplete from a systematic point of view, where we would want to include haptic and gestic media types. Another problem is the inherent inconsistencies of the classification scheme. The distinction between temporal and non-temporal media appears clear cut, but on a closer analysis all so-called non-temporal media have temporal aspects. Text can indeed be statically displayed, but it could also be presented repetitively (blinking), sequentially (one word or noun phrase at a time displayed in a

Figure 1. Media classes as suggested by Gibbs and Tsichritzis (1995); the diagram has been redrawn to make the assumption of the non-temporal media classes explicit in the diagram



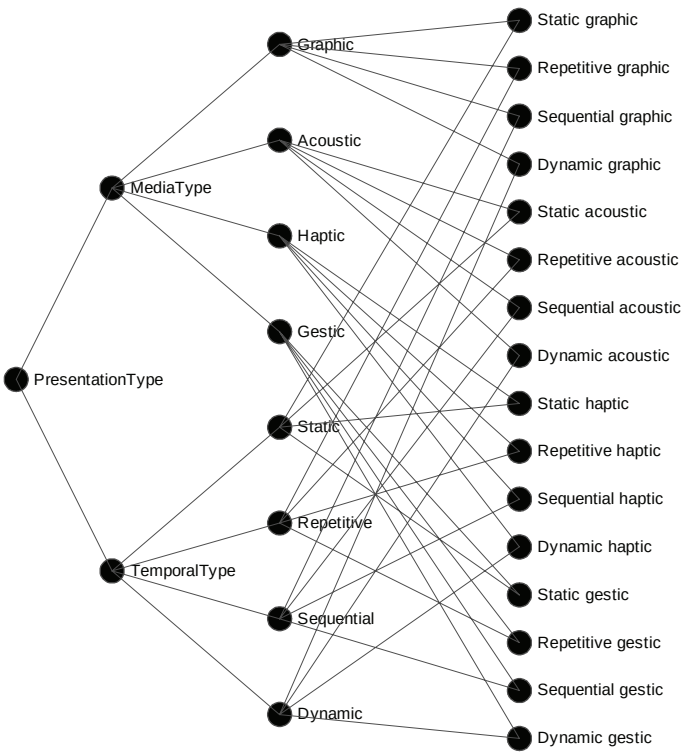
linear fashion as in the "ticker tape display"), or dynamically as in auto-scrolling text on a Web page. The same argument can be made for images and object-oriented graphics, that is, they are not inherently static, but can be presented in different temporal forms. The media type called "animation" now appears to be a derivation of repetitive, sequential, or dynamic versions of other media types. It could be an improvement to differentiate the temporal properties of presentations from the specification of their media type (just as the interactivity of presentations is seen as a separate issue), and a classification scheme like the one constructed in Figure 2 could be defended.

From the classification presented in Figure 2, a series of questions will have to be answered, though. How can, for instance, the acoustic media be ascribed a static form? Although the acoustic media is inherently temporal at a physical level, it does make sense from a perceptual point of view to define a static acoustic media type with reference to sound (in the form of noise or un-modulated tones) that is constant within the duration of the presentation. After considering limit cases like static sound, the same temporal distinctions can be applied to all media resulting in a classification scheme (Figure 2) based on the systematic formation of all logical combinations. The temporal distinctions are static, repetitive, sequential, and dynamic (Bernsen, 1993, 1994).

With regard to the difference between "animation" and "video" suggested by the traditional classification scheme (Figure 1), this distinction breaks down when we consider modern techniques of animated computer graphics and virtual reality in the 3D computer games or in mixed-media film, where animated computer-generated characters and human actors can appear within the same media object. Although animated graphics and video have different technical foundations and origins, there is no longer any fundamental difference between them as systems of communication. The referential difference between "virtual" graphics and "real" photographic presentations have important cognitive and epistemic ramifications, but it does not determine the media type (i.e., graphic/photographic and animation/video are not distinctions in media type).

Finally "animation" is a mixed concept for another important reason: It includes the traditional graphical forms of communication utilised in animated drawings (sequential graphics) as well

Figure 2. A systematic classification of presentation types as derived from media types and four temporal types, as they can be determined beofre the further articulation of representational forms (and before considering spatial and temporal layout issues)



as the embodied movement-based communication realised in facial, hand, and full-body gestures. As channels of communication, we need to distinguish the *gestic media* ("gestures") from the graphical media, although presentations in both channels are visually perceived.

There is a more serious problem with the temporal specification of media types, though: Although temporal specifications in some cases seem to be fundamental to the internal properties essential to media types (as in the case of static graphics versus animation and video), this does not resolve the issue of how this internal temporality is articulated within the temporal organisation of the presentation as a whole. In accordance with the different levels of structure introduced for multimodal documents, we need to separate different issues of temporality in multimedia objects.

Temporal aspects of multimedia objects can appear as important for the type specification of the chosen presentation media for a particular representational content, for instance, whether a graph or a diagram within an instructional document is animated or not. With present-day techniques for multimedia multimodal presenta-

tions such as Java applets for interactive Internet documents or dynamically-constructed graphs within a Maple worksheet for doing mathematical calculations, the difference between static, sequentially-animated, or fully-dynamic graphs or diagrams turns out to be of minor importance at the level of media types. Static, animated, or dynamic versions of the same object will often be available as part of the temporal layout of the instructional document or otherwise put directly under the interactive control of the user. Consequently, distinctions like static, repetitive, sequential, and dynamic should be located at the level of temporal layout and interactivity and not at the level of specification of media types (as an internal property of the type).

Gibbs and Tsichritzis (1995) are aware of another classification problem that arise with the combination of "audio" and "video": We would usually expect "video" to have some sound overlay, but since both audio and video can exist in a "pure" form, we should classify them according to these simple non-combined types and consider audio-visual media types as combinations of simple types (like video, audio, speech, and music).

A more difficult problem of classification, however, is associated with the inconsistent analysis of representational forms supported by different media. Speech is not considered as a type except as collapsed into the audio type, partly because it, in contrast to music represented in the midi encoding format, did not have a separate encoding at the time (cf. the recent VoiceXML format), and partly because there is no thorough analysis of the relation between media types and the representational forms they support.

In early approaches to multimedia content, many obvious relations that would be relevant for content management and for flexible display of multimedia content were almost "hidden" by the classification scheme. A good example is natural language, where the close relation between *text* and *speech* is lost if graphical and acoustic language presentations are only considered as presentations in two different media, and not also as representations within a single *representational form* (natural language). Similarly, the classification scheme hides the fact, well known to any graphical designer, that text is in fact a kind of graphical presentation that inherits many of the operations supported by other forms of object-oriented graphics: operations on shape, size, colour, shading, texture, and orientation (cf. the design space of fonts). These inconsistencies can be resolved, if we abstract the concept of media from specific technologies, programming languages, and their data types, in favour of a perception-based approach to different media, where media types are derived from human sensory abilities in combination with elaborated channels of communication. From this point of view, we only have four different physical presentation media and channels of communication subsumed under computerized control today: the graphic media that derives from visual perception, the acoustic media that derives from auditory perception, the haptic media that derives from tactile and kinaesthetic perception, and the gestic (or "gestural") media that derives from visual perception. The gestic and the graphic should be considered as separate channels of communication because the gestic media is based on the temporal dimension of movement in itself, rather than on its potential for producing graphic traces of movement (as in drawing on some interface).

Sign Types: Core Semantics and Emergent Semantics

From the point of view presented here, many problems of classification arise from the confusion of the physical media of presentation and communication with the representational forms ("sign types"). Natural language is a representational form that can present linguistic content across different media in the form of graphical language (text), in the form of acoustic language (speech), in the form of haptic language (Braille-

embossed text), or in the form of encoded gestures (sign languages). A useful starting point for understanding representational forms is, in fact, to consider them as representational "modalities", not to be confused with sensory modalities, that are invariant across different media (Stenning, Inder, & Neilson, 1995). In their analysis of media and representational forms (which they call "modalities"), Stenning, Inder, and Neilson focused on the invariant differences: The difference between diagrams and language, for instance, is invariant across the tactile and the graphical media. Where the media type is derived from how an object of presentation is communicated and perceived, the representational form (sign type) is derived from how it is interpreted. (the intended interpretation within a context). Braille text as well as graphical text is interpreted as language, whereas graphic and tactile diagrams are interpreted as diagrams. A semiotic and cognitive theory of information presentation is needed to explain this semantic invariance of the intended interpretation, by which representational forms are constituted. It can be claimed, however, that language is a unique representational system in providing this invariance across physical forms, that is, across the phonological and gestic system of expression and across different graphical writing systems, due to the differential nature of linguistic entities. Everything in language is differences, as it was proclaimed by de Saussure.

According to Stenning and Inder (1995), graphical representation systems are different because they rely on a less abstract mapping of relations between the represented domain and relations in the representation (within a presentation media). This should explain why there are graphic and tactile diagrams but apparently no acoustic equivalent, because the transient nature of acoustic media object does not allow diagrammatic relations to be presented and inspected. It is possible, however, to modify the idea of invariant properties as constitutive of the representational forms. According to the modified view, we will stipulate that only a reduced set of core properties are invariant across media and this core is what constitutes the representational form. On top of these core properties, each media affords and provides cognitive support for an extended set of properties and operations that are meaningful within the representational form, although they are not supported in all media.

From this point of view we could in fact have acoustic diagrams, but only in the very limited sense made available for the core properties of diagrams that are supported across all media. Acoustic diagrams would, therefore, be highly schematic with few details, but they could be constructed from external representations corresponding to the embodied image schemata described in cognitive semantics (Johnson, 1987; Lakoff, 1987). Acoustic diagrams would be based on image schematic asymmetries like left/right, up/down, centre/periphery, front/back with simple objects, relations, and events plotted against this background. An example could be the representation in sound of the relative position and movement of enemy aircrafts represented in the cockpit of a fighter aircraft through directional sound: The image schematic background for the acoustic diagram would in many cases be implicit (cf. the discussion of implicitness and expressiveness in Mackinlay & Genesereth, 1985), that is, it would not be explicitly represented but provided through the interpretation by the pilot according to the phenomena of distributed cognition (Zhang, 1996). Another example could be the use of directional 3D sound to indicate location of escape routes on passenger ships, where the traditional static graphic emergency signs could be misleading (in cases of fire blocking some escape routes) and difficult to see (due to smoke) (May, 2004).

It follows from this conceptualisation of media types and representational forms, that a distinction has to be made between the core semantics of the representational forms (sign types) and the extended semantic properties of the well-known prototypes associated with each representational

form. The acoustic maps mentioned above are good examples. They are indeed maps, a diagrammatic representational form, in the restricted sense of the core semantics of the unimodal map, according to which a map is interpreted as a diagram supporting the representation of spatial localization of objects and/or events relative to a reference object. Prototypical maps as we know them from everyday life or professional work (city maps, road maps, sea charts, etc.) are graphical objects with a higher complexity resulting from (a) emergent properties of the expression of maps within the graphical media (such as support for graphically-based inferences about metrical properties like size and distance) and resulting from (b) properties inherited from other representational forms combined with the map object. Most maps are in fact complex multimodal objects because they combine useful features of many unimodal representational forms in order to achieve the usefulness of the prototypical map object. A unimodal city map without overlay of symbols in the form of street names, for instance, would not be very useful. In the case of city maps the combination of types can be understood as a spatially coordinated layering of different forms: a network chart (metro lines) on top of the basic map object (the street map), and symbols (street and metro names) as yet another layer. This conceptual layering of different representational forms is utilised constructively in geographical information systems (GIS), where each layer can be addressed and modified separately.

Towards a Semantics of Multimedia: The Semiotic Turn

A semiotic turn in the analysis of multimedia has been initiated by the Amsterdam multimedia group at CWI. Nack and Hardman (2002) refer to the work of Chatman on film theory (Chatman, 1978) in order to set up the fundamental conceptual aspects of multimedia: the form and substance of multimedia content and the form and substance of multimedia expression. It should be noted that these distinctions of form/substance and content/expression does not originate with film theory, but with the constitution of structural linguistics according to Ferdinand de Saussure (1993) and Louis Hjelmslev (1961). Saussure and Hjelmslev both stipulated a place for a future science of semiotics (or "semiology") derived from the linguistic study of language, but with a focus on the syntactic and semantic properties of other "sign systems". Building on Saussure's distinction between the plane of expression (the "signifiers") and the plane of content (the "signified") in language and on his foundation of linguistics on the differential forms in language as a system, as opposed to its physical "substance" (acoustic, graphic) and its psychological "substance" (ideas, concepts, etc.), Hjelmslev specified these four planes in language (Hjelmslev, 1961).

The four planes can be used to specify different levels of description for multimedia units as shown. A similar description is given by Nack and Hardman (2002), although with a different interpretation of the levels. A more complex semiotic framework for the analysis of multimedia based on structural linguistics in its further development by A. J. Greimas was given by Stockinger (1993).

Note that the standard developed for multimedia content description interfaces for audiovisual media, better known as the ISO MPEG-7 standard, specifies multimedia units at the level of their substance of expression only, and the MPEG standard thus leaves the problem of mapping high-level semantics of media objects unsolved (Nack & Hardman, 2002). Even on its own level as a standard for the substance of expression, there has been some criticism of MPEG-7 for not being extensible and modular enough in its description definition language: It is criticised for its closed set of descriptors, for its non-modular language, and for not being sufficiently object-oriented in its data model (Troncy & Carrive, 2004).

Figure 3. The four plans in language as a system accoring to Saussure/Hjelmslev tradition

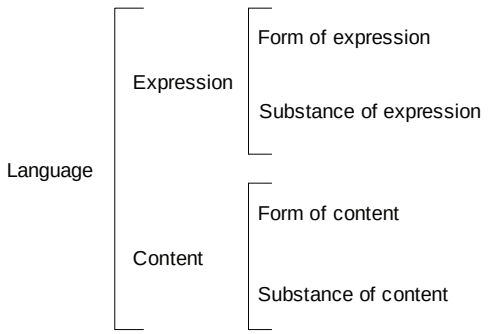


Figure 4. Four fundamental levels of description of multimedia units (not considering the pragmatic and social aspects of the use of multimedia in a specific context-of-use)

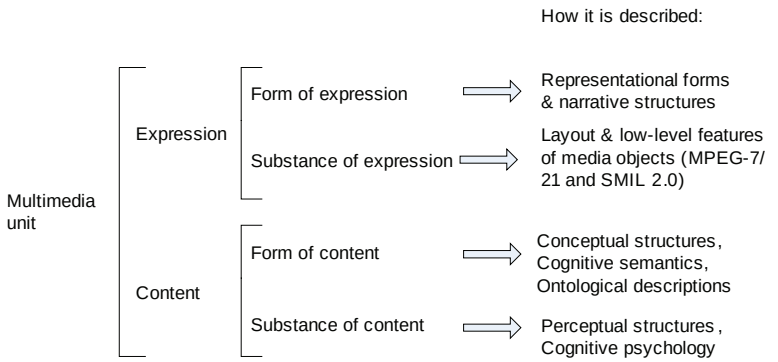


On the level of the form of expression, our focus here is on the basic representational forms rather than on higher-level semantic structures of narration and interaction, and it is comparable to the three-dimensional TOMUS model presented in Purchase and Naumann (2001). The TOMUS model is based on a differentiation between sign types, syntactic structures, and sensory modalities, the latter corresponding to *media* in the present study.

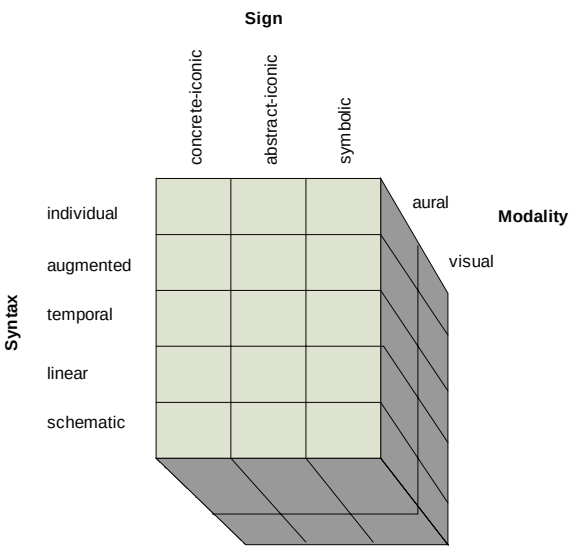
Some taxonomies of multimedia reproduce the difficulties encountered by taxonomies of graphics. An example is the ambiguous classification of media types into text, sound, graphics, motion, and multimedia as suggested by Heller & Martin (1995) and Heller, Martin, Haneef, and Gievska-Krliu (2001). "Motion" is here used to refer to video and animation, which seems like a confusion of form and substance of dynamic graphics. The haptic and gestic media are not considered. The relation between text and graphics is left unanalysed, and the inconsistency in not considering text as a form of graphics is not discovered. The model, however, introduces a second dimension of expression of media types covering three nominal types going from "elaboration" over "representation" to "abstraction". In the case of graphics, this expression dimension is exempli-

fied by the difference between photographs and images at the "elaboration" end, blueprints and schematics as the intermediate form of "representation", and icons at the "abstraction" end. The expression dimension of Heller and Martin (1995) is close to the dimension of the sign in the TOMUS model of Purchase and Naumann (2001), with its subdivision of sign types into concrete-iconic, abstract-iconic, and symbolic.

The iconic-symbolic dimension of sign types have been derived from the semiotic analysis of signs in the work of C. S. Peirce. Where Saussure and later Hjelmslev conceived "semiology" as an extension of linguistics that would study the quasi-linguistic properties of other "sign systems", Peirce developed his more general conception of a "semiotic" from his analysis of logic. For Peirce the sign is not a dyadic relation between expression and content, but a triadic relation between a physical representation (in his terminology, the "representamen"), and an interpretation (the "interpretant") of this representation as referring to an object in some respect. Within this triadic relation, it is the representation-object aspect which is categorised as being iconic, indexical, or symbolic by Peirce. The causal relation implied by the indexical category can be considered as a separate issue from the dimension of iconic – symbolic. A subdivision of the iconic – symbolic dimension was also used as a foundation of the sign typology presented in (May, 1993, 2001; May & Andersen, 2001), with the main categories being image, map, graph, conceptual diagram, language, and symbol. The image and the map category here corresponds to the concrete-iconic sign type in the taxonomy of Purchase and Naumann (2001), the diagrammatic forms of representation – graph and conceptual diagram – correspond to the abstract-iconic sign type, and language and symbol to the symbolic type. The conception of the "diagrammatic" in C. S. Peirce is somewhat broader (Figure 6), since it would include maps in the concrete-iconic end and natural as well as mathematical languages in the symbolic end.

With regard to media, the TOMUS model only distinguishes the aural and the visual senses

Figure 5. The TOMUS model of sign types (i.e., representational forms), syntax, and (sensory) modalities (i.e., media) according to Purchase and Naumann (2001).



supporting the acoustic and the graphic channel of communication. It is, however, an important feature of the model that all combinations of sensory modalities (or rather media) and sign types (representational forms) can be considered in a systematic way. We will not go into the discussion of the syntactic dimension of the model here.

The taxonomy suggested in May (2001) and May and Andersen (2001) relies on a set of fundamental principles, which makes it well suited to support a more formal approach. An initial version of this taxonomy was developed in May (1993) within the GRACE Esprit Basic Research project in collaboration with N. O. Bernsen, who developed his own version (Bernsen, 1993, 1994). It is suggested that:

- There is a limited number of media types derived from sensory modalities and forms of communication relevant for computer-based interaction;
- There is a limited number of possible uncombined representational forms ("unimodal sign types");
- It is possible to give a feature-based description of their semantic properties;
- Some of these properties are invariant across media types whereas other properties and operational possibilities are emergent with the expression of signs within a media;
- Invariant properties (the "core" semantics) are inherited to syntactic combinations of representational forms whereas their emergent properties are constrained by the specific combinations of media types and representational forms.

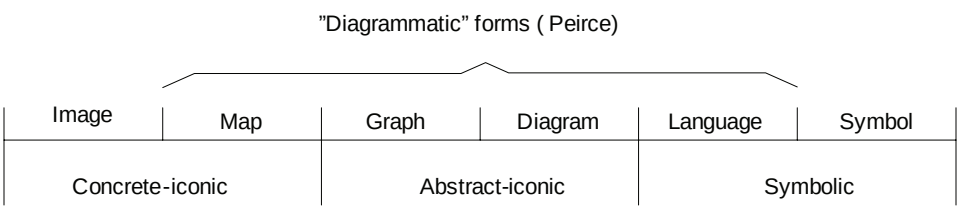
It follows that we cannot expect to find any kind of consistent hierarchical classification of prototypical multimedia objects or even graphical objects, because they will have to include complex objects with overlapping properties. The consistent alternative is to develop a feature-based classification, where we track the inheritance and combination of significant properties of sign types and media types. This will, of course, require that we can define the core semantics of the suggested representational forms and describe them in a way that will be relevant to the actual interpretation and use of complex media objects, where different media and representational forms are combined.

FEATURE-BASED MULTIMEDIA SEMANTICS

Feature-Structures and Multimedia Content

An early suggestion of a feature-based semantics of graphics was given by Alan Manning in a paper on "technical graphics" (Manning, 1989). Manning stipulated four types of technical graphics

Figure 6. Conceptual diagram to indicate the relation between the sign types used in the TOMUS model compared with the taxonomy of representational forms



abstracting from their terminological variants and their apparent similarities and differences: chart, diagram, graph, and table. According to his analysis, these types can be distinguished by logical combination of two features: display of one unit (written as –u) or several units (+u) and the representation of one property (-p) or several properties (+p). Each graphical type in this simple semantic system can thus be described by a small set of feature structures:

chart: [-p, -u] graph: [-p, +u]
diagram: [+p, -u] table: [+p, +u]

A simple pie chart only displays one unit (some totality) and it only represents one property (fractions of the total), whereas a graph like a bar graph has several units (represented by individual bars) and again only one property (the amount represented by the height of each bar). A diagram, however, only represents one unit (some object), but displays several properties of the represented object, whereas a table can represent many units and display several properties of each represented object. Our interest here is in the formal approach using feature structures rather than the actual classification.

From a formal point of view, the feature structure approach corresponds to setting up a lattice of the logical combinations of features. This approach to taxonomy of conceptual structures has been formalised in Formal Concept Analysis (Ganter & Wille, 1999), where features ("attributes") and the concepts they specify (the "objects") are related in a matrix called a formal context. A formal context C:= (G, M, I) is defined as two sets G (from German "Gegenstände", Objects) and M (from German "Merkmale", attributes) with a relation I between G and M. The elements of G are the objects and the elements of M are the attributes or features of the context. From the formal context, all possible combinations of formal concepts can be generated. A formal concept is a pair (a, b) where a belongs to the set of objects G and b belongs to the set of attributes M. In the small example derived from Manning (1989), an example of a formal concept would be the specification of charts as ({Chart}, {-p,-u}). The full list of formal concepts for the context is shown in Figure 7 below together with the Hasse diagram of the corresponding lattice. To construct a lattice, we have to add two points: the "top" element corresponding to the empty set of objects and the union of all attributes and the "bottom" element corresponding to the full list of objects and the empty set of attributes.

Let us return for a moment to the analysis of the core semantics of a representational form

Figure 7. Formal concepts and lattice generated for the graphical types (objects) and the features (attributes) given by the example discussed earlier; the lattice drawing has been made using the Java-based Concept Explorer program "ConExp 1.2".

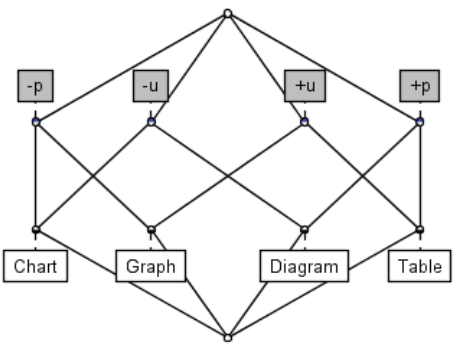
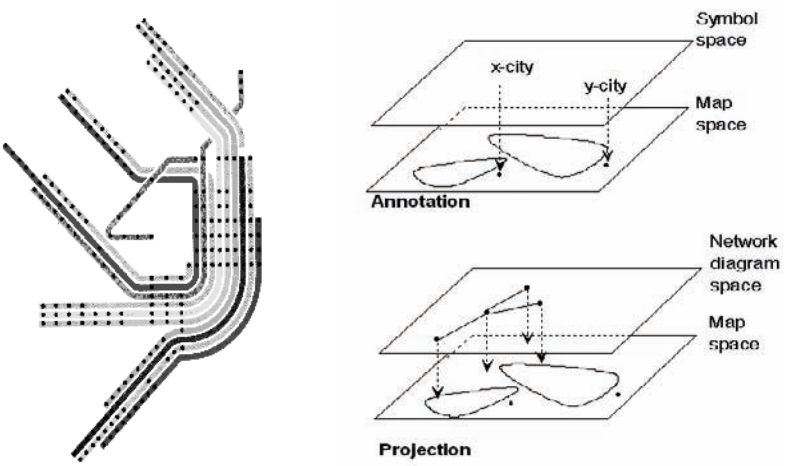
({Chart,Diagram,Graph,Table}, {}) = Bottom



(across all media) as opposed to its emergent semantics articulated within the graphical media. The diagrams used to locate city subway stations are sometimes referred to as "maps", although they are in fact network charts with features quite distinct from the features of maps. Subway charts will often be juxtaposed with timetables, which belong to yet another type of representation, because the combination of tables with information about the time schedule of trains and the network diagram (representing the connectivity and sequence of train stations) gives effective support for navigational decisions. Both representations are, however, virtually useless without the addition of a third representational form: symbolic representations for the denotation of different train stations. The representational form of symbols is also needed to establish a coherent reference between the annotation to the network chart and the content of the table structure. The annotated network charts can furthermore be projected on an underlying map object giving rise to the familiar but complex prototype known as a "city map". City maps are complex multimodal representations that are not fully coherent in their inherent semantics, because the supported operations and the semantic properties of network charts do not fully agree with those of maps. Since network charts focus on the representation of topological properties like the connectivity of nodes and connecting lines in the network and not on its metric properties, the connecting lines can be deformed and distances between nodes can be changed: As long as the connectivity of the network is not changed, it will have the same interpretation (i.e., it will represent the same network). These operations are, however, not supported in a map and there is, therefore, a potential conflict of interpretation in maps with network overlay. In city maps the nodes representing subways stations have to be fixed to their correct location on the map, whereas the shape of connecting railway lines can be idealised and thus not true to the underlying map. This is acceptable because the geometric properties of railway lines are unimportant to passengers. On the other hand, city maps could support false inferences about these properties as seen on the map.

The core semantics of a representational form will necessarily be unimodal even though most concrete practical examples of external

Figure 8. Artificially reconstructed "unimodal" network chart (derived from a subway map) (to the left) and the (re-) construction by annotation and projection of a multimodal map object by spatially coordinated layering of different representational spaces (to the right)



representation will be multimodal. We can artificially construct a unimodal map by "reverse engineering" of a city subway diagram like the one shown below to the left (an early version of the Copenhagen subway system), but it is virtually useless because the labelling of stations have been removed.

We can utilise the Formal Concept Analysis (FCA) for graphical types and generalise it to cover the full range of multimodal multimedia objects. FCA have already been extended to cover constructive aspects of diagram design (Kamps, 1999) and multimodal document layout (Bateman, Kamps, Kleinz, & Reichenberger, 2001), but what has not yet been fully recognised is the potential benefits of extending the description of objects with semiotic metadata about the representational forms articulated and combined within different media. This type of information would not only be relevant for the constructive generation of multimodal multimedia documents, but also for the design of flexible distributed documents, for instance, in supporting changes in representational form in moving Web-based documents to PDA interfaces. The issue of flexibility here is not just a question of how to deal with layout constraints imposed by different devices, but also a question of designing support for adaptation or tailoring through transformations of representational scales (Johansen & May, in press), media types as well as representational forms (sign types).

Consider again maps and network charts as two different representational forms. We can express what this difference means, in terms of the semantic features and supported operations associated with each form within different media, by setting up the formal context for these simple "unimodal" objects. The following example is just given as a sketch of what such an analysis could look like, and this simplified formal context only includes five objects and four attributes (semantic features and supported operations):

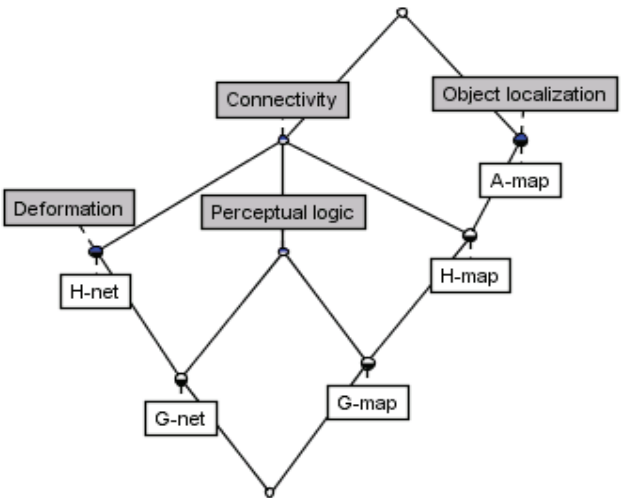
- **Connectivity:** Does the type require connectivity to be preserved?
- **Perceptual logic:** Does the type support "direct perception" of logical relations in a spatial structure (cf. Lakoff, 1990; May, 1999)?
- **Deformation:** Does the type support and allow deformation?
- **Object localization:** Does the type support localzation of objects relative to a background object?

It is implied by this analysis that the well-known graphical maps, although they are prototypical maps, do not exemplify the *core semantics* of maps. It is in fact the apparently peripheral case of the acoustic map (A-map in Figure 10) that exemplifies the *core* semantics of maps, because it is the attributes of acoustic maps (in the example here reduced to the feature "Object localization") that is shared by all maps. Graphical maps, of course, also have this feature, but in addition they have other emergent features

Figure 9. Table indicating a part of the formal context specifying the map and the network chart types articulated in different media

C	onnectivity	Perceptual logic	Deformation	Object localization
Graphical map (G-map)	+	+		+
Haptic map (H-map)	+			+
Acoustic map (A-map)				+
Graphical net (G-net)	+	+	+	
Haptic net (H-net)	+		+	

Figure 10. A Hasse-diagram of the lattice corresponding to the formal concepts specifying maps and network charts according to the simplified formal context sketched in Figure 9



derived from the graphical media (Connectivity and Perceptual logic).

We can visualise this through the inheritance hierarchy embedded within the lattice as shown in Figure 11. The core feature of maps (object localization) as exhibited by acoustic maps is inherited to haptic maps and graphical maps.

Lattice structures are well-suited to express feature structures, because they can express inheritance relations as well as systematic combinations of types. We can even use them to generate possible combinations of representational forms in cases where we might not know a prototypical example in advance, that is, we can use lattices to explore the design space of all possible type combinations and their expression in different media —given a full set of features necessary to distinguish the formal concepts involved.

The concept of a lattice is based on the concept of an ordering of types through the binary relation ≤. Defining this relation on a set, we obtain a partially ordered set (sometimes just called a partial order), if for all elements of the set, the following is true:

$x \leq x$ (Reflexivity)
$x \leq y \ \& \ y \leq x$ implies $x = y$ (Anti-symmetry)
$x \leq y \ \& \ y \leq z$ implies $x \leq z$ (Transitivity)

If every pair in the set has both a "supremum" (a least upper bound) and an "infimum" (a greatest lower bound) within the set, we have a lattice ordering <L, ≤>. From any lattice ordering <L, ≤> we can construct a lattice algebra <L,, > with two binary operations called join () and meet () by defining x y = sup{x,y} and x y = inf {x,y}. This equivalence of the order theoretic and the algebraic definition of a lattice is important, because it means that we can construct operations on a lattice given the ordering of its elements (Davey & Priestley, 1990). This is what is utilised in formal concept analysis (Ganter & Wille, 1999).

Figure 11. The lattice of Figure 10 used to show the inheritance of the "core feature" of maps (object localisation) from the acoustic map type; the object localisation feature is shared by all maps.

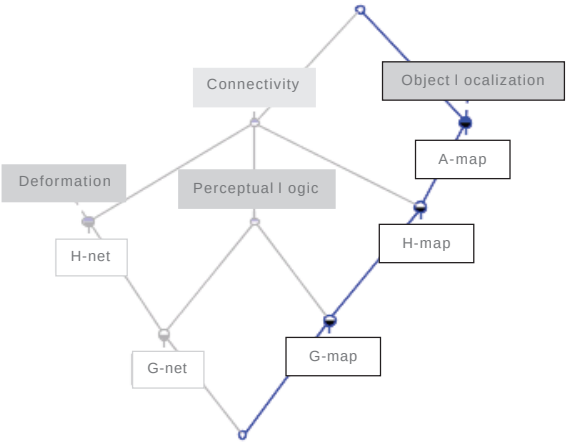


Figure 12. The lattice of Figure 10 used to show the specification of graphical nets (G-net) as the lattice "meet" of Deformation (a core semantic feature of network charts) and Perceptual logic (an emergent feature of the graphical media); by inheritance graphical nets are also characterized by Connectivity (a shared feature of the graphical and haptic media).

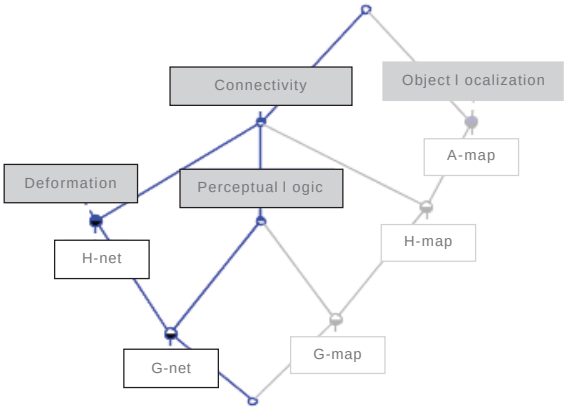

FEATURE-BASED TAXONOMY FOR INSTRUCTIONAL DESIGN

Related Approaches to Multimedia Semantics

The extension of feature-based approaches to multimedia semantics has followed different tracks, since the first attempts to specify features of graphical objects. One track has followed the work on automated presentation of information (Mackinlay, 1986) and another track have analysed perceptual and representational scales for relational information displays (Petersen & May, in press; Zhang, 1996). A third track can be identified around the problem of indexing im-

ages as well as indexing and sequencing video for databases (Dorai & Venkatesh, 2001, 2003), but this work has mainly dealt with low-level features, that is, features of the graphical substance of expression. Even when explicitly addressing the "semantic gap" between the physical substance of recorded film and the semantic issues of content management systems, the kind of semantics that is proposed is based on feature extraction from low-level data, although guided by film grammar. The focus on feature extraction is grounded in the practical interest in automatic segmentation and indexing of video. A fourth track is linked to the attempt to define semantic content for multimedia and hypermedia on "the semantic Web", but the standards developed for Web-based multimedia and hypermedia also have its main focus on the substance of expression and to a lesser extend on the form of expression. A good example is the advanced XML-based spatial and temporal layout facilities for media objects realised in the Synchronized Multimedia Integration Language (SMIL 2.0) (Bulterman, 2001).

From SMIL Encoding of Multimedia to Learning Object Metadata

The SMIL specification language for multimedia on the Web and for mobile devices can in many ways be seen as the realisation of the potential inherent in object-oriented multimedia with regard to the substance of expression. With SMIL 2.0, authors can specify the temporal behavior of individual elements of a presentation, their spatial layout, the hypermedia structure of the distributed objects included in the presentation, and its overall compositional structure.

The basic syntax of SMIL presentations is very similar to HTML syntax and is easy to read and edit. For a simple example, look at the following presentations that could be part of a multimedia instruction in how to play chess. Here a chess game has been visualised through a video recording of a particular game. The SMIL object is played back through the RealPlayer, but could also be embedded on a Web page. The first piece of code simply presents the recording of the board as captured in the file "board.rm".

A more advanced example is shown below, where the space within the player window is subdivided into four regions, one of which is used to display a textual comment synchronised with the moves of the particular chess game. The other three regions are used to display different visual perspectives on the game: the "black" player, the board, and the "white" player. In parallel with the synchronised graphical channels, an audio channel is added to present additional speech comments on the game.

The chess example above has been produced in a project on digital video in educational research and it is accordingly not meant as an instructional object for teaching or learning how to play chess. We can, however, use it here as a point of departure for discussing the relation between the encoding of multimedia documents and the metadata required for their use in instructional design of learning objects.

A learning object is a modularized self-contained unit of instructional material that has been given a metadata description of its own content and use. Ideally these instructional materials are available in digital electronic form through a learning object repository (shared over the Internet, for example). As described by David Wiley, "learning objects are elements of a new type of computer-based instruction grounded in the object-oriented paradigm of computer science. Object-orientation highly values the creation of components (called "objects") that can be reused … in multiple contexts. This is the fundamental idea behind learning objects: instructional designers can build small (relative to the size of an entire course) instructional components that can be reused a number of times in different learning contexts." (Wiley, 2000, chap. 3, p. 1). There are however, as Wiley also points out, important

Figure 13. SMIL code use to present a recorded movie sequence

Figure 14. theoretical problems to be addressed with regard to the granularity of these objects (their minimal "size" within the instructional material of a whole course) and with regard to semantic and cognitive constraints (what makes sense, what gives cognitive support) as well as pragmatic constrains on compositionality (what has practical value within a context-of-use). We need to go beyond a naïve "Lego"-conception of learning objects.

The chess video example could be considered as a learning object provided that we associate it with relevant metadata describing its intended use within an instructional setting. It is in fact already a learning object within its original context, where it is used as an illustration of how to use SMIL for editing and presenting digital video. The very re-use of the chess example in the present context illustrates both the potential of learning objects and an inherent weakness: By completely changing the context and reusing the object with a purpose, for which it was not designed (chess instruction), it will be difficult to determine in advance, if the object is really useful and adequate in the new context. In any case, we will need detailed metadata describing the learning object and its intended use, but we cannot expect instructional designers to anticipate all possible context of reuse. If learning objects are to be retrieved and reused, they will therefore have to be designed with some level of flexibility and a combination of detailed information about the intended context-of-use (to support identifica-

```

tion of similar learning situations) and abstract compositional descriptions of their form and content independent of any specific use (to support transformations of the object and its transfer to other learning situations). Before discussing these demands on metadata, let us stay with the fictive example of the chess learning object.

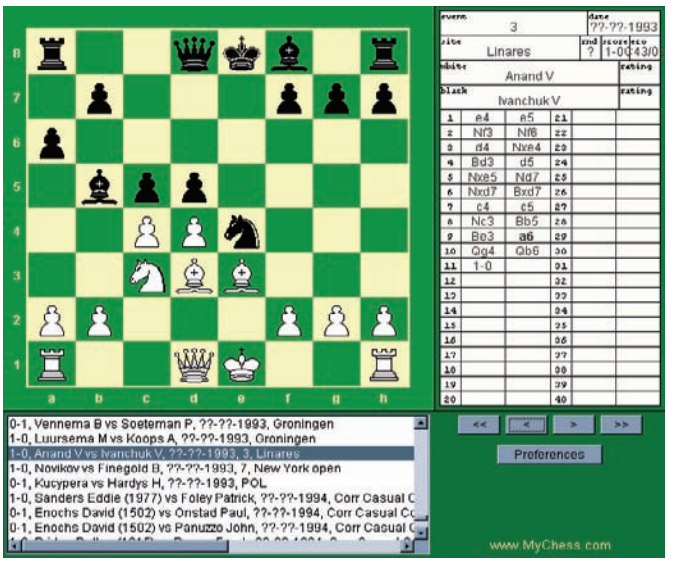
As a first observation, it should be noted that video playback only provides a limited level of interactivity. A learner would very soon in the learning process need to be actively engaged in playing chess (i.e., using a chess simulator or playing chess with a human opponent), rather than watching a game passively through recorded sequences of game play. On the other hand, even this simple example illustrates the learning potential of using multiple representations within multimedia learning objects. The chess example uses the representational form of language expressed as graphical text (for comments in the subtitle region) and as acoustic speech (for synchronised "voice over") in combination with dynamic graphics (the video). Combining a graphical display of the game with voice could be an effective support for basic learning according to the cognitive theory of multimedia learning proposed by Mayer (2001). According to Mayer's so-called "modality principle", students will learn better when the language part of a multimedia document is presented in the acoustic media (i.e., as voice) rather than in the graphical media (i.e., as text), because this use of voice for comments within the multimedia presentation will be less demanding on cognitive processing (since the visual-graphical channel is already used for static graphics, animation, or video). This principle has also been referred to as "dual coding theory", that is, referring to the utilisation of the capacity of visual as well as auditory working memory.

There is another important issue, however, that is not addressed adequately by the cognitive theory of multimedia learning. The "dual coding"

theory stays within a media-specific dichotomy between the visual and the auditory channel of communication, and representational forms are more or less reduced to "pictures" and "words". Although Mayer (2001) uses different diagrams in his empirical investigations, they are treated as "pictures" at the theoretical level. This makes it difficult to address didactic aspects of learning with different forms of representation. In our small example with the hypothetical learning object for multimedia support of chess learning (Figure 14), it is obvious that chess learning beyond the initial stages of getting acquainted with the context of chess playing would benefit from relying on "abstract-iconic" representations of the relational structure of the game and its strategic situations rather than on "concrete iconic" representations like images (animated or not). In other words, we need the familiar chess diagrams to support game analysis, and this requires that we abstract from the irrelevant features of the concrete situation of game play (unless our focus is the psychology of game players rather than the game itself).

In learning chess, we would in fact abstract diagrams representing the strategic situations from observing a video, but the mental work required to do so would be less demanding if these abstractions were supported by a sequence of external diagrams. This is an important educational implication of the variable cognitive support provided by different external representations according to the theory of distribution between external and internal (cognitive) representations (Petersen & May, in press; Zhang, 1996)). Image type representations will be less effective and less adequate as cognitive support for chess learning and understanding compared to diagrams (including their algebraic notation) for two different reasons: Images will necessarily qua images represent features that are irrelevant to the relational structure of the game (demanding us to abstract from them) and the symbolic structure of chess will

Figure 16. The MyChess Java applet illustrates a more powerful form of playback, where chess diagrams are used in combination with their algebraic notation to support analysis of the game (here Anand - Ivanchuk in Linares, 1993). The applet also presents a database from which the current game is selected (source: http://www.mychess.com)



require us to see in the image "something more" than is directly visible, that is, the diagrammatic form (May, 1999). This is why the external diagram and its algebraic equivalent are more effective, that is, less cognitively demanding.

Professional chess players will require more interactive features and more functionality to support further learning than can be realised with playback of recorded games. With the full simulation provided by a game engine, the expert will not only use a program like Fritz to play against a virtual opponent, but also to perform dynamic thought experiments on the external diagrammatic representations in order to explore the game space and evaluate different strategies. This exploration corresponds to what the founding father of logical semiotics, C. S. Peirce, called "diagrammatic reasoning" (Peirce, 1906).

Extending Learning Object Metadata

As shown in the previous example, it is generally not enough to know which media are utilised by some learning objects in order to evaluate their usefulness and their cognitive support for specific activities and contexts-of-use. We also need to know details about the representational forms used by learning objects. This type of information has not yet been included in the design of metadata for learning object repositories. If we again depart from a SMIL example of a learning object, but this time one that has been give a metadata description, we can take the SMIL presentation of a lecture in "Membranes and Cell Surfaces" from a BioScience course given at University of Queensland.

The metadata given is primarily formal (author, version, department, institution, etc.), deictic (date, place, presenter) and superficial content descriptions (subject, description). An important information about the level of learning that the learning object is assumed to address is given by the statement of the audience being "First Year Biology Students" at a university, but it is not stated what the specific learning objectives for the lesson is (what are students supposed to be able to do after using the object or after taking the course?), or indeed what form of learning and instruction is supported by the lesson? On inspecting the online lesson, it turns out to be a recorded audio and video sequence of a traditional lecture, with added notes and diagrams in a separate region. This type of presentation can be presented with a SMIL 2.0 player or embedded within a website. Alternatively a similar presentation can be made with Microsoft Power Point Producer (available for Office 2003). In any case there is no metadata standard for describing the representational forms used by learning objects and what kind of cognitive support this gives for the intended activity within a context-of-use.

Learning objects have been given several competing XML-based standards or specifications in the form of the IEEE Learning Object Metadata (LOM), the Instructional Management System (IMS) Metadata, and the Sharable Content Object Reference Model (SCORM), to mention just three different models. Although these standards and specifications are supposed to be neutral to different contexts-of-use, there have been many objections towards their implementation in higher education. The SCORM standard, for example, promoted by the Advanced Distributed Learning initiative (ADL), sponsored by the U.S. Department of Defense, has a bias toward distributed learning situations with single learners engaged in self-paced and self-directed learning (Friesen, 2004). This is well suited for instructional design of individual Web-based training, but less so for the pedagogical use of learning objects within group-based and class-based teaching and learning at the university level.

The metadata specified by the standards focus on formal document information, technical requirements, superficial content descriptions (like keywords), and general educational information (like interactivity level, resource type, duration of use), but generally neglect more specific infor-

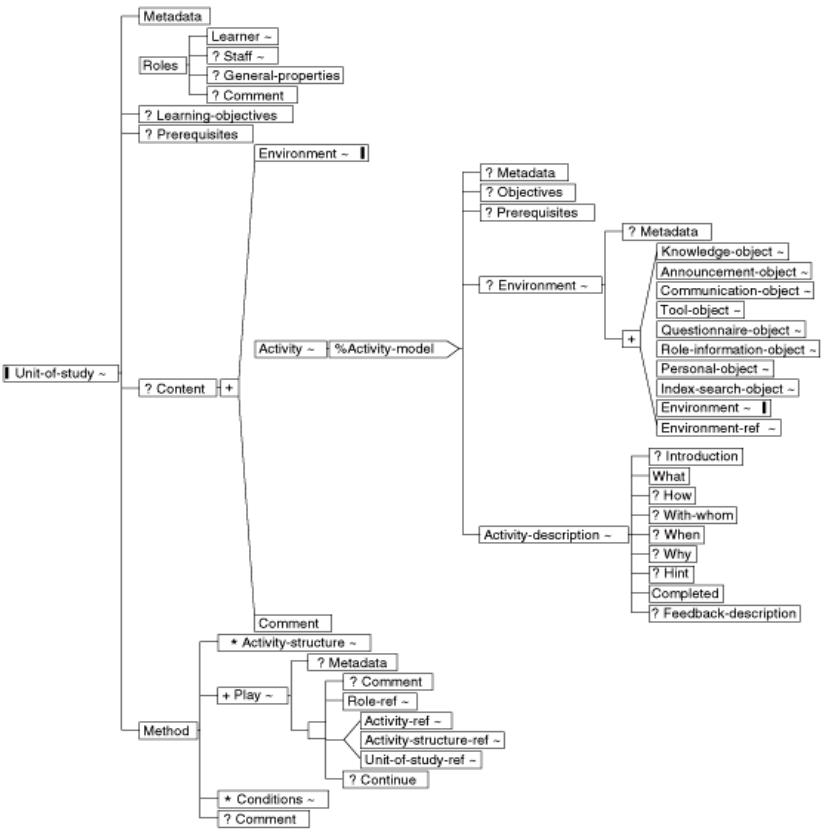
mation about the content. Content specifications should include more detailed information about the scientific domain to which the object refers, the prior knowledge required by the learner to benefit from its use, the learning objectives for the use of the object, and its intended scenarios of use. This type of information is included within the Dutch proposal for a more elaborated Educational Modelling Language (EML), which goes beyond learning objects in order to model the whole activity of teaching and learning, the methods used, and the different roles of the social agents involved (Koper, 2001; Koper & van Es, 2004). EML is proposed as "a major building block of the educational Semantic Web" (Anderson & Petrinjak, 2004, p. 289).

This extension of the modelling perspective from the objects of instructional design, that is, teaching materials, to include the whole activity of teaching and learning, might however be counter-productive and impractical. The perspective of learning objects should not be to formalise the whole activity of teaching and learning, but to package electronically-available learning objects with metadata relevant for teaching and learning, and to embed them in object repositories for future reuse. They should, however, be tagged with some of the information provided with EML, but only as tools for reuse, not as a part of a codification of the whole activity.

There are also alternative conceptions of learning objects like the Reusable Learning Assets (RLA) proposed within the Open Course initiative (http://opencourse.org), which are defined as open source, non-proprietary learning objects.

What is lacking in all projects, however, even in the detailed modelling of "units of study" in EML, is the relevant metadata information about the media types and representational forms utilised by the learning object. This information is relevant because there is evidence that variance and integration of representational forms are important for student learning, even if there has been some debate over the specific "modality effects" of media on learning. Early experimental work on the "effects of media" on learning did

Figure 18. EML specification of a unit of study



not produce consistent findings (Hede, 2002), but conflicting conceptions of learning have also confused the issue. In the "effects of media" debate there was originally a conception of learning as transmission of information, and teaching was accordingly seen as a simple matter of communication, whereas learning in modern conceptions involves constructive conceptual activity by students. Even in modern studies it is, however, not always clear whether the "modality effects" claimed for multimedia learning is due to the duality of audio and visual coding, that is, a consequence of the use of acoustic and graphic media types, or due to the multiplicity of different representational forms such as language, diagrams, graphs, and images.

THE EXAMPLE OF GRAPH COMPREHENSION

The theoretical critique of Mayer's cognitive theory of multimedia learning (CTML) has been backed up by empirical studies. Schnotz and Bannert (2003) found that adding graphical representations to text presentations did not always result in improved understanding. In some cases the "pictures" could actually have negative effects by interfering with the construction of mental models. They conclude that the "dual coding theory" of multimedia learning does not take into account the effects that different forms of visualisation will have on the construction of mental models from the presentation in the process of comprehension. In another study it was found

that the "affordances" of graphical representations for improving conceptual understanding should be seen in the context of specific scientific domains and also as dependant on familiarity with the specific "iconic sign system" from which the representations are derived (De Westelinck, Valcke, De Craene, & Kirschner, 2005). It seems, for instance, that students in the social sciences are less familiar with graphs and conceptual diagrams than students of natural sciences, and they will therefore not have the same benefits from these abstract-iconic forms. Learners can only benefit from representations if they understand the semantics of the representational forms to which they belong (Cox, 1999).

A striking example is the problems of graph comprehension reported in many studies of science learning in high school as well as in higher learning. An early example is the studies of students' understanding of kinematics and problems of associating graphs with their physical interpretation (Beichner, 1994; McDermott, Rosenquist, & van Zee, 1987). A recent review of the literature on graph comprehension (Shah & Hoeffner, 2002) supports these early findings and lists four implications for teaching graphical literacy: (1) graphical literacy skills should be taught explicitly (and in the context of different scientific domains), (2) activities where students have to translate between different types of representations will improve their understanding, (3) students need to pay attention to and be trained in the relation between graphs and the models they express, and (4) students should be encouraged to make graph reading a "meta-cognitive" activity, that is, to pay attention to and reflect critically on the interpretation of graphs.

One of the typical problems found in graph comprehension, even in higher education, is the interpretation of graphs as "concrete iconic" objects, that is, images rather than relational structures. An example found in students of chemical engineering at DTU were errors in reasoning about a test on Fourier's law for heat conduction, where some students, who tried to remember the graph by its shape (a graphical image feature) rather than by the conceptual model it expresses, reported the correct shape of a curved graph, but as a mirror image of its correct orientation (May, 1998).

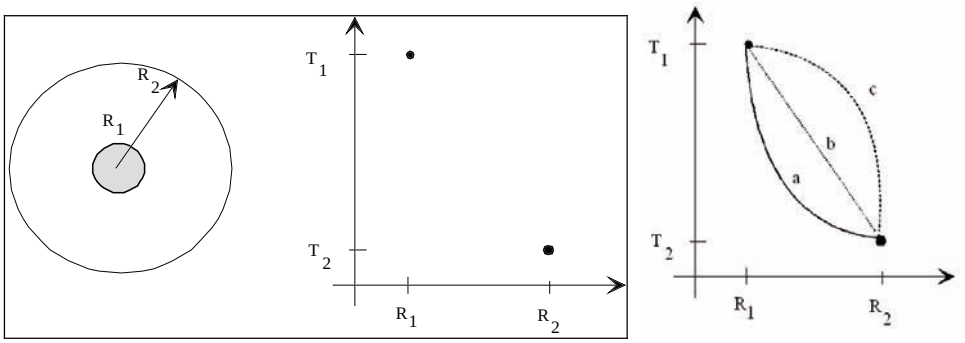
The students who answered (c) to the test in Figure 19 could not give any physical interpretation to the graph since it was remembered as a mere image of a textbook (or lecture) presentation. This exemplifies a "typological error" within the representational forms used in reasoning by the students: treating a graph as if it was an image (or effectively reducing it to a mental image).

In order to support the didactic suggestions by Shah and Hoeffner (2002) and others regarding the need to train graph comprehension skills in higher education, learning objects need to be annotated with metadata on their level of interactivity (to distinguish learning objects with active exploration of models from more or less static illustrations, for example) and on their support for active student learning through translations between different representational forms (as in conceptual tests motivating students to transform graph representations, algebraic expressions, or natural language descriptions of models).

The taxonomy of representational forms introduced in this chapter can be used to extend existing standards for learning object metadata with this type of information (as well as specifications of learning objectives).

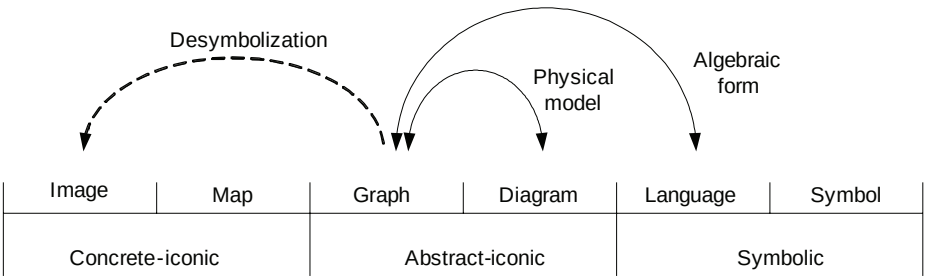
In a recent study, it was found that students working actively with integrating multiple static representations, before working with animations and simulations, have better learning outcomes than students who directly explore dynamic and interactive visualisations (Bodemer, Ploetzner, Bruchmüller, & Häcker, 2005). This is again empirical evidence that indicates the importance of the integration of multiple forms of representation for conceptual understanding. In the context of instructional design of learning objects for object repositories, it will be necessary to extend current XML-based standards for metadata with infor-

Figure 19. A conceptual test (to the left + caption) given to students in a course in chemical engineering at DTU (1995); three types of answers were given by students: the correct answer (a), the linear answer (b), which is motivated by the original context where students learned about the law (where it is in fact linear, if the area is not considered), and (c) where student have remembered the shape of the image, but without any physical understanding of the model represented by the graph (May, 1998)



[Original caption to the test:] Consider a cylinder with radius R_2. Inside the cylinder is a kernel with radius R_1 and which has been heated to the temperature T_1. At the surface (with radius $r = R_2$) the temperture is held constant at T_2 where $T_2 < T_1$. Show in the diagram a qualitative sketch of the graph T(r) for values between R_1 and R_2 (i.e., you do not have to compute any values for points on the curves).

Figure 20. Conceptual diagram to indicate the "desymbolisation" of graphs reduced to concrete-iconic images by some students and the didactic importance of training students actively in "translating" between graphs and their "diagrammatic" interpretation in terms of their underlying physical models as well as between graphs and the formal algebraic models which they express



mation about the representational forms utilised by learning objects. This will enable teachers engaged in instructional design of learning objects to make better choices in setting up conditions for active learning, since students will benefit from being exposed to many different representations of the same content. In engineering education, for instance, it is important to set up learning environments where students can work actively with static graphs, algebraic forms, explanations in natural language, and conceptual diagrams, as well as animated graphs and interactive simulations: Conceptual understanding emerges from the discovery of invariant forms across all of these media and "modalities."

SUMMARY

A better understanding of the invariant semantic properties of representational forms across different media will be important in the future support for flexible configurable interfaces and for supporting the design of device-independent multimedia and other forms of adaptive multimedia.

In the domain of instructional design and in the redesign of instructional material as learning objects for Web-based learning and for learning repositories, it is of primary importance to extend current standards for learning objects with (a) didactic specifications of the intended use of these objects and (b) semiotic and semantic information about the media and representational forms supported by the learning objects.

An approach to the taxonomy of media types and representational forms has been suggested, based on feature structures and Formal Concept Analysis. More research is needed in order to combine the analysis of media types and representational forms with the analysis of scale types and scale transformations (Petersen & May, in press), and to apply both to the domain of adaptive and configurable interfaces as well as to the domain of instructional design.

Chapter 2.8
Cognitively Informed Multimedia Interface Design

Eshaa M. Alkhalifa
University of Bahrain, Bahrain

INTRODUCTION

The rich contributions made in the field of human computer interaction (HCI) have played a pivotal role in shifting the attention of the industry to the interaction between users and computers (Myers, 1998). However, technologies that include hypertext, multimedia, and manipulation of graphical objects were designed and presented to the users without referring to critical findings made in the field of cognitive psychology. These findings allow designers of multimedia educational systems to present knowledge in a fashion that would optimize learning.

BACKGROUND

The long history of human computer interaction (HCI) has witnessed many successes represented in insightful research that finds its way to users' desktops. The field influences the means through which users interact with computers—from the introduction of the mouse (English et al., 1967) and applications for text editing (Meyrowitz & Van Dam, 1982) to comparatively recent areas of research involving multimedia systems (Yahaya & Sharifuddin, 2000).

Learning is an activity that requires different degrees of cognitive processing. HCI research recognized the existence of diversity in learning

styles (Holt & Solomon, 1996) and devoted much time and effort toward this goal. However, Ayre and Nafalski (2000) report that the term *learning styles* is not always interpreted the same way and were able to offer two major interpretations. The first group believes that learning styles emerge from personality differences, life experiences, and student learning goals, while the second group believes that it refers to the way students shape their learning method to accommodate teacher expectations, as when they follow rote learning when teachers expect it.

The first interpretation includes, in part, a form of individual differences but does not explicitly link them to individual cognitive differences, which, in turn, caused researchers more ambiguities as to interpreting the different types of learning styles. In fact, these differences in interpretations caused Stahl (1999) to publish a critique, where he cites five review papers that unite in concluding the lack of sufficient evident to support the claim that accommodating learning styles helps to improve children's learning when acquiring the skill to read. He criticized Carbo's reading style inventory and Dunn and Dunn's learning inventory because of their reliance on self-report to identify different learning styles of students, which, in turn, results in very low replication reliability.

These criticisms are positive in that they indicate a requirement to base definitions on formal replicable theory. A candidate for this is cognitive learning theory (CLT), which represents the part of cognitive science that focuses on the study of how people learn the information presented to them and how they internally represent the concepts mentally in addition to the cognitive load that is endured during the learning process of the concepts.

Some of the attempts that were made to take advantage of the knowledge gained in the field include Jonassen (1991), van Jooligan (1999), and Ghaoui and Janvier (2004).

Jonassen (1991) advocates the constructivist approach to learning, where students are given several tools to help them perform their computation or externally represent text they are expected to remember. This allows them to focus on the learning task at hand. Jonassen (1991) adopts the assumption originally proposed by Lajoie and Derry (1993) and Derry (1990) that computers fill the role of cognitive extensions by performing tasks to support basic thinking requirements, such as calculating or holding text in memory, and thus allowed computers to be labeled cognitive tools. Jonassen's (1991) central claim is that these tools are offered to students to lower the cognitive load imposed during the learning process, which, in turn, allows them to learn by experimentation and discovery.

Van Jooligan (1999) takes this concept a step further by proposing an environment that allows students to hypothesize and to pursue the consequences of their hypotheses. He did this through utilizing several windows in the same educational system. The system was composed of two main modules: the first supports the hypothesis formation step by providing menus to guide the process; the second provides a formatted presentation of experiments already tested and their results in a structured manner. They also added intelligent support to the system by providing feedback to students to guide their hypothesis formation approach.

Ghaoui and Janvier (2004) presented a two-part system. The first part identified the various personality types, while the second either had an interactive or non-interactive interface. They report an increase in memory retention from 63.57% to 71.09% that occurred for the students using the interactive interface. They also provided a description of the learning style preferences for the students tested, which exhibited particular trends, but these were not analyzed in detail.

Montgomery (1995) published preliminary results of a study aimed at identifying how mul-

timedia, in particular, can be used to address the needs of various learning styles. Results indicate that active learners appreciate the use of movies and interaction, while sensors benefit from the demonstrations.

Although a glimmer of interest in CLT exists, there is a distinct lack of a clear and organized framework to help guide educational interface designers.

ALIGNMENT MAP FOR MULTIMEDIA INSTRUCTIONAL INTERFACE

The problems that arose with learning styles reveal a need for a more fine-grained isolation of various cognitive areas that may influence learning. Consequently, an alignment map, as shown in Table 1, may offer some guidelines as to what aspects of the multimedia interface design would benefit from what branch of the theory in order to gain a clearer channel of communication between the designer and the student.

CASE STUDY: DATA STRUCTURES MULTIMEDIA TUTORING SYSTEM

The alignment map presents itself as an excellent basis against which basic design issues of multimedia systems may be considered with the goal of making the best possible decisions.

The multimedia tutoring system considered here (Albalooshi & Alkhalifa, 2002) teaches data structures and was designed by considering the various design issues as dictated by the alignment map that was specifically designed for the project and is shown in Table 1. An analysis of the key points follows:

1. **Amount of Media Offered:** The system presents information through textual and animated presentation only. This is done to avoid cognitive overload caused by redundancy (Jonassen, 1991) that would cause students to find the material more difficult to comprehend.
2. **How the Screen is Partitioned:** The screen grants two-thirds of the width to the animation window that is to the left of the screen, while the verbal description is to the right. Although the language used for the textual description is in English, all students are Arabs, so they are accustomed to finding the text on the right side of the screen, because in Arabic, one starts to write from the right hand side. This design, therefore, targeted this particular pool of students to ensure that both parts of the screen are awarded sufficient attention. It presents an interface that requires divided attention to two screens that complement each other, a factor that, according to Hampson (1989), minimizes interference between the two modes of presentation.
3. **Parallel Delivery of Information:** Redundancy is desired when it exists in two different media, because one re-enforces the other. It is not desired when it exists within the media, as when there is textual redundancy and things are explained more than once. Consequently, the textual description describes what is presented in the animation part, especially since only text and animation media exist in this case, which means that cognitive load issues are not of immediate concern (Jonassen, 1991).
4. **Use of Colors:** Colors were used to highlight the edges of the shapes and not on a wide scale to ensure that attention is drawn to those. By doing so, focus is expected to be directed toward the object's axes, as suggested by Marr and Nishihara (1978), in order to encourage memory recall of the shapes at a later point in time.
5. **Use of Animation:** The animated data structures are under the user's control with

Table 1. Alignment map from multi-media design questions to various cognitive research areas that may be of relevance

Multimedia Design Issues	Cognitive Areas That May Be of Relevance
1. Amount of media offered 1	. Cognitive load 2. Limited attention span 3. Interference between different mental representations
2. How the screen is partitioned 1	. Perception and recognition 2. Attention
3. Parallel delivery of information	1. Redundancy could cause interference 2. Limited working memory (cognitive load issues) 3. Limited attention span 4. Learner difference
4. Use of colors	1. Affects attention focus 2. Perception of edges to promote recall
5. Use of animation	1. Cognitive load reduction 2. Accommodates visualizer/verbalizer learners
6. Use of interactivity	1. Cognitive load reduction 2. Raises the level of learning objectives
7. Aural media	1. Speech perception issues like accent and clarity 2. Interference with other media
8. Verbal presentation of material	1. Clarity of communication 2. Accommodates verbal/serialist learners

respect to starting, stopping, or speed of movement. This allows the user to select whether to focus on the animation, text, or both in parallel without causing cognitive overload.

6. **Use of Interactivity:** The level of interactivity is limited to the basic controls of the animation.
7. **Aural Media:** This type of media is not offered by the system.
8. **Verbal Presentation of Material:** The verbal presentation of the materials is concise and fully explains relevant concepts to a sufficient level of detail, if considered in isolation of the animation.

EVALUATION OF THE SYSTEM

The tool first was evaluated for its educational impact on students. It was tested on three groups: one exposed to the lecture alone; the second to a regular classroom lecture in addition to the system; and the third only to the system. Students were distributed among the three groups such that each group had 15 students with a mean grade similar to the other two groups in order to ensure that any learning that occurs is a result of the influence of what they are exposed to. This also made it possible for 30 students to attend the same lecture session composed of the students of groups one and two, while 30 students attended the same lab session composed of the students of groups two and three in order to avoid any confounding factors.

Results showed a highly significant improvement in test results of the second group when their post-classroom levels were compared to their levels following use of the multimedia system, with an overall improvement rate of 40% recorded with $F=9.19$, with $p < 0.005$ from results of an ANOVA test after ensuring all test requirements had been

satisfied. The first and third groups showed no significant differences between them.

Results shown indicate that learning did occur to the group that attended the lecture and then used the system, which implies that animation does fortify learning by reducing the cognitive load. This is especially clear when one takes the overall mean grade of all groups, which is around 10.5, and checks how many in each group are above that mean. Only six in group one were above it, while 11 were above it in group two and 10 in group three. Since group three was exposed to the system-only option and achieved a number very close to group two, which had the lecture and the system option, then clearly, multimedia did positively affect their learning rate.

Since one of the goals of the system is to accommodate learner differences, a test was run on group two students in order to identify the visualizers from the verbalizers. The paper-folding test designed by French et al. (1963) was used to distinguish between the two groups. The test requires each subject to visualize the array of holes that results from a simple process. A paper is folded a certain number of folds, a hole is made through the folds, and then the paper is unfolded. Students are asked to select the image of the unfolded paper that shows the resulting arrangement, and results are evaluated along a median split as high vs. low visualization abilities.

These results then were compared with respect to the percentage of improvement, as shown in Table 2. Notice that the question numbers in the pre-test are mapped to different question numbers in the post-test in order to minimize the possibility of students being able to recall them; a two-part question also was broken up for the same reason.

Results indicate that, although the group indeed was composed of students with different learning preferences, they all achieved comparable overall improvements in learning. Notice, though, the difference in percentage improvement in Question 4. The question is: List and explain the data variables that are associated with the stack and needed to operate on it. This particular question is clearly closer to heart to the verbalizer group than to the visualizer group. Therefore, it should not be surprising that the verbalizer group finds it much easier to learn how to describe the data variables than it is for students who like to see the stack in operation. Another point to consider is that the visualizer group made a bigger improvement in the Q1+Q8 group in response to the question: Using an example, explain the stack concept and its possible use. Clearly, this question is better suited to a visualizer than to a verbalizer.

FUTURE TRENDS

CLT already has presented us with ample evidence of its ability to support the design of more informed

Table 2. The percentage improvement of each group from the pretest to the posttest across the different question types

	Q1 PLUS Q8 MAPPED TO Q1	Q3 MAPPED TO Q2	Q4 MAPPED TO Q3	Q6 MAPPED TO Q6
VISUALIZER GROUP	27.8%	18.6%	9.72%	9.76%
T-TEST RESULTS	.004	.003	.09	.01
VERBALIZER GROUP	20.7%	22.8%	21.4%	15.7%
T-TEST RESULTS	.004	.005	.003	.009

and, therefore, more effective educational systems. This article offers a map that can guide the design process of a multimedia educational system by highlighting the areas of CLT that may influence design. The aim, therefore, is to attract attention to the vast pool of knowledge that exists in CLT that could benefit multimedia interface design.

CONCLUSION

This article offers a precise definition of what is implied by a computer-based cognitive tool (CT) as opposed to others that were restricted to a brief definition of the concept. Here, the main features of multimedia were mapped onto cognitive areas that may have influence on learning, and the results of an educational system that conforms to these design requirements were exhibited.

These results are informative to cognitive scientists, because they show that the practical version must deliver what the theoretical version promises. At the same time, results are informative to educational multimedia designers by exhibiting that there is a replicated theoretical groundwork that awaits their contributions to bring them to the world of reality.

The main conclusion is that this is a perspective that allows designers to regard their task from the perspective of the cognitive systems they wish to learn so that it shifts the focus from a purely teacher-centered approach to a learner-centered approach without following the route to constructivist learning approaches.

KEY TERMS

Alignment Map: A representation on a surface to clearly show the arrangement or positioning of relative items on a straight line or a group of parallel lines.

Attention: An internal cognitive process by which one actively selects which part of the environmental information that surrounds them and focuses on that part or maintains interest while ignoring distractions.

Cognitive Learning Theory: The branch of cognitive science that is concerned with cognition and includes parts of cognitive psychology, linguistics, computer science, cognitive neuroscience, and philosophy of mind.

Cognitive Load: The degree of cognitive processes required to accomplish a specific task.

Learner Differences: The differences that exist in the manner in which an individual acquires information.

Multimedia System: Any system that presents information through different media that may include text, sound, video computer graphics, and animation.

INTRODUCTION

Embedded systems have several constraints which make the development of applications for such platforms a difficult task: memory, cost, power consumption, user interface, and much more. These characteristics restrict the variety of applications that can be developed for embedded systems. For example, storing and playing large videos with good resolution in a limited memory and processing power mobile device is not viable.

Usually, a client-server application is developed to share tasks: clients show results while servers process data. In such a context, another hard task for limited memory/processing devices could be delegated to the server: storage of large data. If the client needs data, it can be sent piece by piece from the server to the client.

In this article we propose a layered architecture that makes possible the visualization of large videos, and even other multimedia documents, in memory/processing limited devices. Storage of videos is performed at the server side, and the client plays the video without worrying about

storage space in the device. Data available in the server is divided into small pieces of readable data for mobile devices, generally JPEG files. For example, when the client requests videos from the server, the videos are sent as JPEG files and shown at an ideal rate for users. The video frames are sent through a wireless connection.

The remainder of this article is organized as follows. We begin by describing background concepts on embedded systems and client-server applications, and then present our solution to enable multimedia applications in memory-limited mobile devices. We next discuss some future trends in mobile multimedia systems, and finally, present concluding remarks.

BACKGROUND

Embedded Systems

An embedded system is not intended to be a general-purpose computer. It is a device designed to perform specific tasks, including a programmable computer. A considerable number of products use embedded systems in their design: automobiles, personal digital assistants, and even household appliances (Wayne, 2005). These limited systems have some constraints that must be carefully analyzed while designing the applications for them: size, time constraints, power consumption, memory usage and disposal, and much more (Yaghmour, 2003).

These constraints restrict the variety of software for embedded systems. The development of applications which demand a large amount of memory, for example, is not viable for embedded systems, because the memory of such devices is limited. Extra memory can also be provided, but the total cost of application is very high. Another example is multimedia applications, such as video players: storing and playing large videos with good resolution in a limited memory and processing power mobile device is a very hard task.

There are specific platforms that were developed to perform multimedia tasks: embedded video decoders and embedded digital cameras, for example. However, other considerable parts of embedded systems, like personal digital assistants (PDAs) and cell phones, are not designed to play videos with good quality, store large amount of data, and encode/decode videos. Thus, it is important to design solutions enabling multimedia environments in this variety of memory/processing-limited devices.

Layered and Client-Server Architectures

Layered architectures share services through a hierarchical organization: each layer provides specific services to the layers above it and also acts as a client to the layer below (Shaw & Garlan, 1996). This characteristic increases the level of abstraction, allowing the partition of complex problems into a set of tasks easier to perform. Layered architectures also decouple modules of the software, so reuse is also more easily supported. As communication of layers is made through contracts specified as interfaces, the implementation of each module can be modified interchangeably (Bass & Kazman, 1998).

Most of the applications have three major layers with different functionalities: presentation, which handles inputs from devices and outputs to screen display; application or business logic, which has the main functionalities of the application; and data, which provides services for storing the data of the application (Fastie, 1999).

The client-server architecture has two elements that establish communication with each other: the front-end or client portion, which makes a service request to another program, called server; and the back-end or server portion, which provides service to the request. The client-server architecture allows an efficient way to interconnect programs that are distributed at different places (Jorwekar, 2005). However, the client-server architecture

is more than just a separation of a user from a server computer (Fastie, 1999). Each portion has also its own modules: presentation, application, and data.

ENABLING MULTIMEDIA APPLICATIONS

Multimedia applications demand a considerable amount of resources from the environment in order to guarantee quality of service, which can be defined in terms of security, availability, or efficiency (Banâtre, 2001). Embedded systems have several constraints, like limited memory (Yaghmour, 2003), which make it very difficult to implement multimedia applications in an embedded platform.

Today, the growing interest for mobile devices and multimedia products requires the development of multimedia applications for embedded systems (Banâtre, 2001). There are approaches (Grun, Balasa, & Dutt, 1998; Leeman et al., 2005) that try to enhance embedded systems memory and other system aspects, such as processing, to provide better results in multimedia applications. However, most of the solutions available focus on hardware architecture, and a large number of programmers are not used to programming at the hardware level.

A solution based on client-server architecture is a good proposal for limited-memory/processing mobile devices because harder tasks can be performed by the server side whereas the client just displays results. By designing applications based on an architecture that shares tasks, constraints like limited memory and low computing power are partially solved. In this article, we propose a layered, client/server architecture that allows playing and storing large videos on limited-memory/processing mobile devices. The data is sent through a wireless intranet.

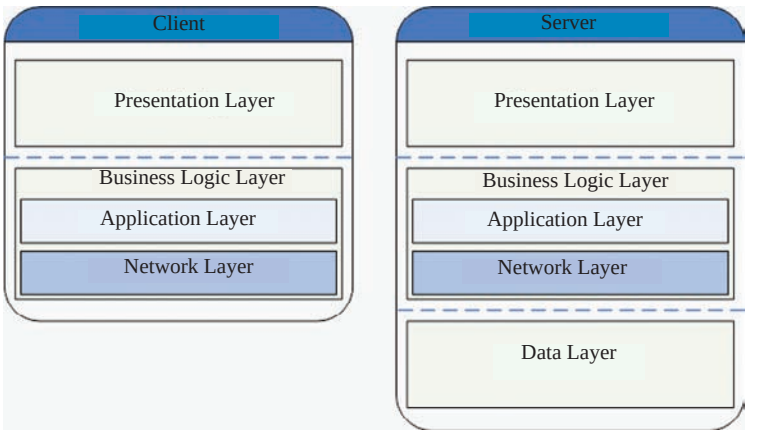
Client/Server Architecture

In Figure 1, both client and server modules are illustrated. Each module of both elements can be changed at any time, except the application layer because the rules of application are defined on it: if business logic changes, so does the application.

The server architecture is a standard three-tier architecture:

- **Presentation Layer:** This layer interacts directly with the client. Its functionalities are related to display forms so that the user adds multimedia content to the server repository.

Figure 1. Client/server architecture

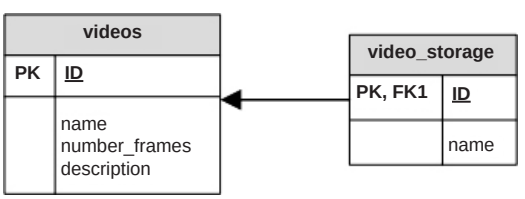


- **Business Logic Layer:** This has two sublayers: the network layer, which manages the connection of server and client, receiving requests and sending responses; and the application layer, which requests services for the data layer, such as document storage and reports.
- **Data Layer:** This layer stores the multimedia documents as JPEG files. Each document has information about management files, including ID, number of frames (JPEG files), and specific description elements, which depends on the multimedia document type. Figure 2 illustrates the logic model of the tables that contain such information. The server stores in a table (video_storage) the titles and ID of all videos. All the information about a video is stored in another table (videos).

The client is a single two-tier application; the data layer is not defined.

- **Presentation Layer:** This consists of a video player with buttons to select the video and a screen to display the video.
- **Business Logic Layer:** This has two sublayers: the network layer, which manages the connection with the client, sending requests to the server and receiving data from it; and the application layer, which gets frames from the network layer and also controls the tax rate of displaying the frames.

Figure 2. Logic model of video descriptions information



Execution Scenario

In what follows, we present an execution scenario of the mobile multimedia architecture. For this, consider that, at server side, a video was divided into small pieces of readable data (JPEG files). The quantity of pieces depends on the desired quality of the video that will be played at the client side.

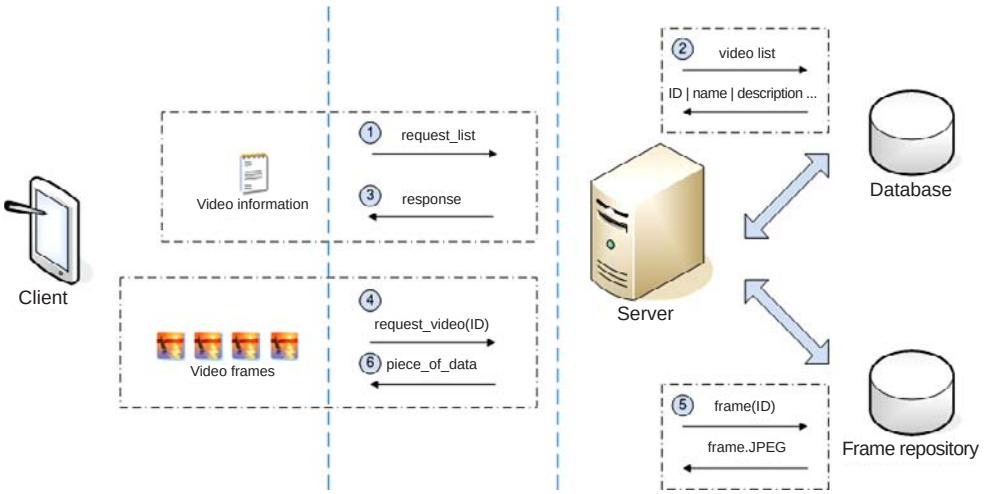
The communication process between client and server is illustrated in Figure 3 and is described as follows. Whenever the server receives a connection request from a client, it sends to the client the list of available videos (steps 1 and 2). The client receives data and displays this information whenever required (step 3). Then, the client sends to the server the ID of the requested video (step 4). The server receives the request and starts the transmission of the video, piece by piece (steps 5 and 6).

At the client side, the pieces of data (JPEG files) are received in a tax rate that depends on the network (traffic, band, etc.). However, to display frames to the client in a constant tax rate and guarantee quality of service, it is necessary to maintain a buffer, which is controlled by the video player.

In the architecture described, the data is sent through a wireless intranet. The pieces of data are JPEG files, but could also be in Motion JPEG (MJPEG) format. The tax of frames depends on the quality of the video player on the client side: generally, a high video quality rate is 30 frames per second, whereas a low video quality rate is 10 frames per second.

In a wireless network, this solution needs a large part of the network bandwidth. Therefore, there is a tradeoff between memory/processing capacity and network bandwidth. Nevertheless, considering home entertainment environments, such a tradeoff is worth the cost mainly because wireless networks in home environments have enough bandwidth to be used in such a context.

Figure 3. Client/server communication



The architecture can also be used for other kinds of multimedia documents. For example, large PDF documents cannot be visualized with good quality on memory/processing-limited devices. The PDF documents can be also shared as JPEG files and sent to the client.

FUTURE TRENDS

A protocol defines communication between client and server. It is an important element to guarantee QoS. As for future work, we suggest a deeper study of protocols enabling a good service for a given situation. It is important to focus on protocols that do not demand a lot of resources from the network, such as bandwidth.

There are some protocols that are implemented over UDP, for example, trivial file transport protocol (TFTP) (RFC 783, 1981) and real-time transfer protocol (RTP) (RFC, 1996). These protocols were implemented to demand few resources of the network, and to transfer a considerable number of files through the network.

Another interesting research approach is to measure variables of the network while using an application based on the architecture described, for example, to define how many devices running such applications the network supports.

CONCLUSION

Multimedia applications demand a considerable amount of resources from systems. To develop multimedia applications for embedded systems, it is necessary to tackle constraints inherent to such platforms, such as limited memory and processing power.

In this article, we described a general architecture used for enabling multimedia applications in memory/processing systems. The architecture has two parts: a server, which receives requests and sends responses to clients; and clients, which make requests. Both parts have a layered architecture.

The solution proposed is relatively simple to implement and is easy to maintain, because the modules are decoupled and can be modified interchangeably. However, the architecture demands a considerable amount of network bandwidth, because the number of packages sent by the server to the client is large. Nevertheless, considering that the application is implemented over a wireless

network in home environments, the bandwidth tradeoff is worth the cost.

KEY TERMS

Client-Server Architecture: A basic concept used in computer networking, wherein servers retrieve information requested by clients, and clients desplay that information to the user.

Embedded Systems: An embedded system is a special-purpose computer system, which is completely encapsulated by the device it controls. An embedded system has specific requirements and performs pre-defined tasks, unlike a general purpose personal computer.

Embedded Software: Software designed for embedded systems.

Layered Architecture: The division of a network model into multiple discrete layers, or levels, through which messages pass as they are prepared for transmission.

Mobile Devices: Any portable device used to access a network (Internet, for example).

Multimedia Application: Applications that support the interactive use of text, audio, still images, video, and graphics.

Network Protocols: A set of rules and procedures governing communication between entities connected by the network.

Wireless Network: Networks without connecting cables, that rely on radio waves for transmission of data.

ABSTRACT

An enhanced mobile healthcare multi-collaborative system operating over Third Generation (3G) mobile networks is presented. This chapter describes the design and use of this system in different medical and critical emergency scenarios provided with universal mobile telecommunications system (UMTS) accesses. In these environments, it is designed to communicate healthcare personnel with medical specialists in a remote hospital. The system architecture is based on advanced signalling protocols that allow multimedia multi-collaborative conferences in IPv4/IPv6 3G scenarios. The system offers real-time transmission of medical data and videoconference, together with other non real-time services. It has been optimized specifically to operate over 3G mobile networks using the most appropriate codecs. Evaluation results show a reliable performance over IPv4 UMTS accesses (64 Kbps in the uplink). In the future, advances in m-Health systems will make easier for mobile patients to interactively get the medical attention and advice they need.

INTRODUCTION

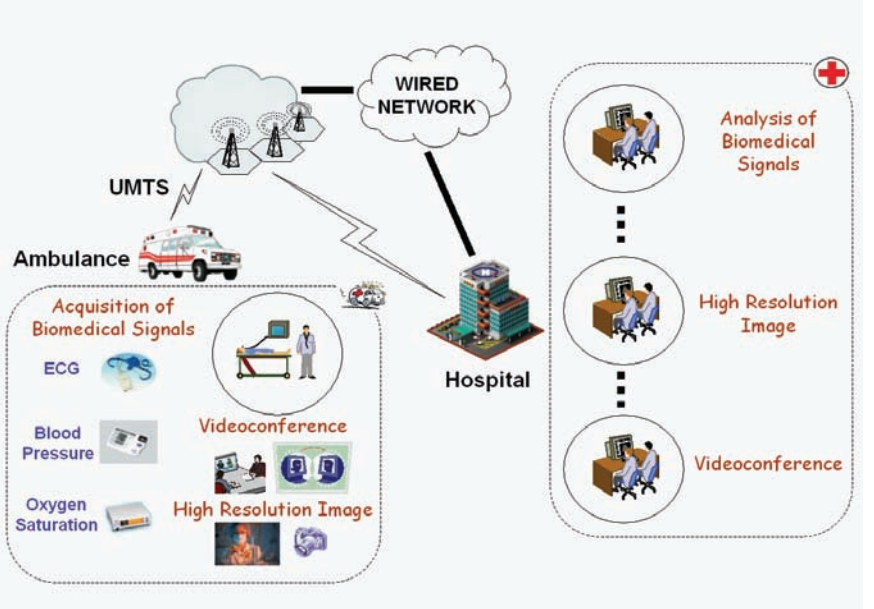
Mobile health (m-health) is an emerging area of telemedicine in which the recent development in mobile networks and telemedicine applications converge. m-health involves the exploitation of mobile telecommunication and multimedia technologies and their integration into new mobile healthcare delivery systems (Istepanian & Lacal, 2003). Wireless and mobile networks have brought about new possibilities in the field of telemedicine thanks to the wide coverage provided by cellular networks and the possibility of serving moving vehicles. One of the first wireless telemedical systems that utilized second-generation (2G) global system for mobile communications (GSM) networks addressed the electrocardiogram (ECG) transmission issues (Istepanian, 2001a). In recent years, several m-health and wireless telemedical systems based on GSM were reported (Istepanian, 2001b), allowing the accomplishment of remote diagnosis in mobile environments, as well as communication to geographic zones inaccessible by wired networks. The recent developments in digital mobile telephonic technologies (and their impact on mobility issues in different telemedical and telecare applications) are clearly reflected in the fast growing commercial domain of mobile telemedical services. A comprehensive review of wireless telemedicine applications and more recent advances on m-health systems is presented in Istepanian, Laxminarayan, and Pattichis (2005).

However, 2G-based systems lack the necessary bandwidth to transmit bandwidth-demanding medical data. The third-generation (3G) universal mobile telecommunications system (UMTS) overcomes limitations of first and second mobile network generations supporting a large variety of services with different quality of service (QoS) requirements. However, this fact makes network design and management much more complex. New applications require networks to be able to handle services with variable traffic conditions keeping the efficiency in the network resources utilization. The UMTS air interface is able to cope with variable and asymmetric bit rates, up to 2 Mbps and 384 kbps in indoor and outdoor environments, respectively, with different QoS requirements such as multimedia services with bandwidth on demand (Laiho, Wacker, & Novosad, 2000). In this kind of scenario, the emergence of 3G mobile wireless networks will permit to extend the use of m-health applications thanks to the provided higher transmission rates and flexibility over previous mobile technologies.

UMTS introduces the IP multimedia core network subsystem (IMS) (3GPP, 2005a), an IPv6 network domain designed to provide appropriate support for real-time multimedia services, independence from the access technologies and flexibility via a separation of access, transport and control. The fundamental reason for using IPv6 is the exhaustion of IPv4 addresses. Support for IPv4 is optional, but since network components require backward compatibility, it is clear that a dual stack configuration (IPv4 and IPv6) must be provided. The IMS uses the session initiation protocol (SIP) as signalling and session control protocol (Rosenberg et al., 2002). SIP allows operators to integrate real-time multimedia services over multiple access technologies such as general packet radio service (GPRS), UMTS or, ultimately, other wireless or even fixed network technologies (interworking multimedia domains). This chapter presents a 3G-based m-health system designed for different critical and emergency medical scenarios, as shown in Figure 1. Several medical specialists in the hospital take part in a multipoint conference with the ambulance personnel, receiving compressed and coded biomedical information from the patient, making it possible for them to assist in the diagnosis prior to its reception.

The 3G system software architecture includes intelligent modules such as information compression and coding, and QoS control to significantly improve transmission efficiency, thus optimizing the use of the scarce and variable wireless channel

Figure 1. Typical medical mobility scenario



bandwidth compared to previous systems (Chu & Ganz, 2004; Curry & Harrop, 1998). Finally, unlike Chu and Ganz (2004), this m-health system follows a multi-collaborative design which supports IPv6/IPv4 interworking, uses SIP as the service control protocol and integrates new real-time multimedia features intended for 3G wireless networks.

3G M-HEALTH SYSTEM ARCHITECTURE

In this section, the 3G m-health system structure is described in detail. The system (see the system components in Figure 2 and the main application graphical user interface (GUI) in Figure 3) has been built using standard off-the-shelf hardware, instead of developing propriety hardware as in Cullen, Gaasch, Gagliano, Goins, and Gunawardane (2001), uses free software and commercially available 3G wireless UMTS cellular data services. In addition, it provides simultaneous transfer of, among other services, videoconference, high-resolution still medical images and medical data, rather than only one media at a time (Kyriacou, 2003; Pavlopoulos, Kyriacou, Berler, Dembeyiotis, & Koutsouris, 1998).

The 3G m-health system consists of different modules that allow the acquisition, treatment, representation and transmission of multimedia information. The modular design of each medical user service allows great flexibility. In addition, there exist other medical user services like chat and electronic whiteboard that allow data exchange in order to guide the operations performed by remote users.

The medical signals module acquires, compresses, codes, represents, and transmits medical signals in real time. The medical signals acquisition devices included are: a portable electrocardiograph that allows the acquisition of 8 real and 4 interpolated leads of the ECG signal, and that follows the standard communication protocol-ECG (SCP-ECG); a tensiometer that provides systolic and diastolic blood pressure values; and a pulsioximeter that offers the blood oxygen saturation level (SpO_2) and the cardiac pulse.

The details of the 3G system architecture are shown in Figure 4 and Figure 5. As it can

Figure 2. 3G m-Health system

Figure 3. m-Health application GUI

be seen, the system comprises of the signalling and session control, medical user services and application control sub-systems, which will be described later.

This architecture allows the 3G system to offer real-time services such as medical data transmission (ECG, blood pressure, heart rate and oxygen saturation), full-duplex videoconference, high-resolution still images, chat, electronic whiteboard, and remote database Web access.

Communication between the remote ambulance personnel and medical specialists is established by means of multipoint multi-collaborative sessions through several network environments capable of supporting the different types of multimedia traffic (Figure 4). The selected con-

Figure 4. 3G network scenario

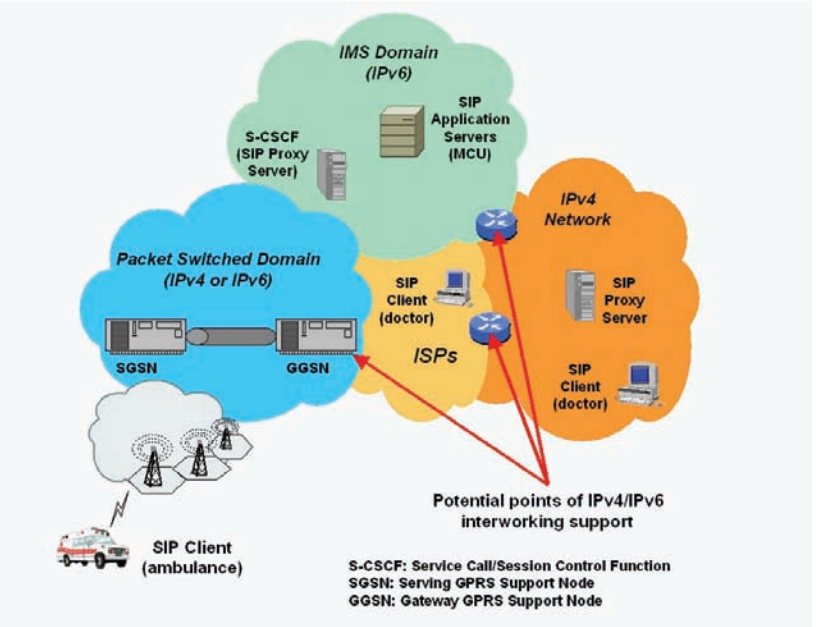


Figure 5. Block diagram of the m-Health system architecture and sub-systems

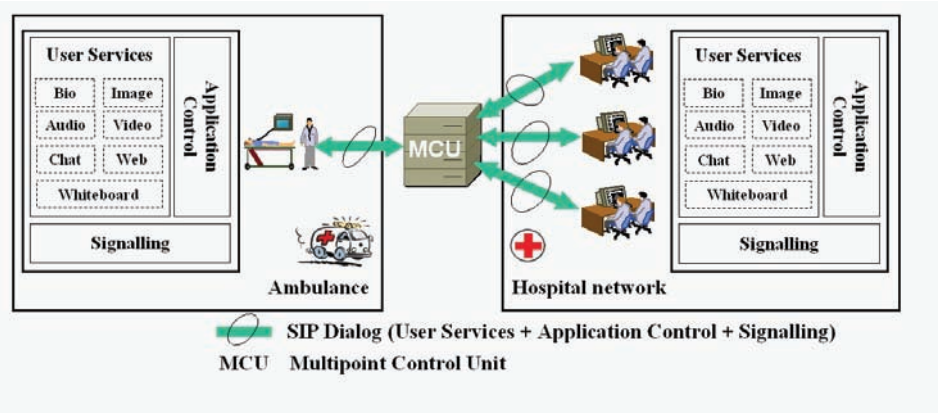


ference model (tightly coupled conference model (Rosenberg, 2004)) requires the existence of a MCU (multipoint control unit) to facilitate multipoint operation. The MCU maintains a dialog with each participant in the conference and is responsible for ensuring that the media streams which constitute the conference are available to the appropriate participants. The MCU can belong to mobile's home network (SIP application server) or to a external service platform. Furthermore, the m-health system is developed to support IPv4/IPv6 interworking (Wiljakka & Soinien, 2003) and can be integrated in a 3G network scenario (see Figure 4).

The MCU receives the information generated by each participant in the multipoint conference, processes and forwards it to the appropriate destinations. System users and the MCU exchange

information associated with the different services provided (medical user services) and its presentation (application control). Moreover, they exchange information related to communication and service quality management (signalling). Next, a detailed description of the sub-systems is presented.

Signalling and Session Control

The developed signalling allows the exchange of the characteristics associated to the different information flows between system elements and is based on standard protocols that favour interoperability. Signalling tasks, performed by the SIP protocol, begin with the establishment of a SIP dialog with the MCU in which, by means of session description protocol (SDP) messages, the different services are described. In order to do that, each element in the system has a SIP user agent (UA), slightly modified in the MCU to allow the use of multiple simultaneous dialogs.

In addition to session control functions (establishment, management and termination of the multipoint conference), the SIP protocol is also useful for user mobility purposes inside the IMS environment.

Multipoint conference establishment, management and termination is performed by exchanging SIP messages between the different users. When a user connects, he creates a SIP dialog with the MCU, joining the conference. During the conference, SIP messages are exchanged between users and the MCU, varying conference characteristics and therefore allowing its management. In a similar process to that of conference joining, when a user wants to leave it, this fact must be communicated to the MCU with the necessary SIP messages. SIP messages also serve as the mean of transport of SDP messages with the description of medical user services.

The QoS in this system is mainly determined by the characteristics of the UMTS link. Mobile links are very variable, therefore a QoS-monitoring process is required in order to obtain a good system performance. This process is especially important in the MCU because it is there where the QoS-related decisions are taken. When the MCU detects that a particular conference participant needs to modify the characteristics of its multimedia session in order to improve QoS, it renegotiates the corresponding session by sending SIP/SDP messages. Hence, conference participants can modify certain upper-level protocol parameters (codecs used, transmission rates, compression ratios, etc.) in order to adapt the transmitted information to network performance.

The QoS monitoring process is possible thanks to a transport library that provides a uniform interface to send the information generated by medical user services and different QoS estimation tools developed for several types of links. This transport library offers different queuing policies and tools designed to measure the following QoS-related parameters: delay, bandwidth and packet loss rate. Due to the variable nature of wireless links, reception buffers have been properly dimensioned to minimize jitter, delay and packet loss.

Wireless Medical User Services

The medical user services included in the m-health system are associated with information shared in a multi-collaborative environment. Specifically, the system has services to share audio, video, medical data information, high-resolution still images, and graphical and textual information, as well as a Web service that allows remote access to clinical information databases. In addition to these services, there is a service designed to exchange control information (application control), which is discussed later.

Each kind of information is associated with a medical user service and uses a transport protocol and a codec according to its characteristics (see Table 1). Hence, real-time services (audio, video, and medical data information) use the real-time

Table 1. Codec operation modes for 3G real-time wireless medical user services

	CODEC	CODEC RATE
Audio	AMR*	4.75 5.15 5.9 6.7 7.4 7.95 10.2 12.2 (Kbps)
Video	H.263	5 10 (Frames per second)
Biomedical Signals	WT**	5 10 20 (Kbps)

* **Adaptive Multi-Rate**

** **Wavelet Transform**

** Adaptive multi-rate, ** Wavelet transform*

transport protocol (RTP), whereas the rest of the services use the transmission control protocol (TCP). Furthermore, the exchanged information can be very sensitive and requires a secure communication. The 3G m-health system uses an IP security protocol (IPSec) implementation supporting public key certificates in tunnel mode. This protocol ensures private communication of selected services.

The ECG signal is stored both in transmission and reception following the SCP-ECG standard. It is well known that for an efficient transmission an ECG compression technique has to be used. In our implementation, a real-time ECG compression technique based on the wavelet transform is used (Alesanco, Olmos, Istepanian, & García, 2003). This is a lossy compression technique, therefore the higher the compression ratio (lower the transmission rate), the higher the distortion at reception. It is clear that there is a trade-off between transmission rate and received ECG signal quality. From the transmission efficiency point of view, a very low transmission rate is desired but from the clinical point of view, a very distorted ECG is useless. Therefore, there exists a minimum transmission rate to be used so as the transmitted ECG is useful for clinical purposes, which was selected in collaboration with cardiologists after different evaluation tests. The minimum transmission rate used in our implementation (625 bits per second and per ECG lead) leads to a clinically acceptable received ECG signal.

Regarding blood pressure, oxygen saturation, and heart rate, these signals have low bandwidth requirements and, therefore, are not compressed.

The videoconference module captures, sends, and plays audio and video information obtained by means of a Web camera and a microphone. In order to reduce the bandwidth, these data are compressed and coded. The video signal is compressed following the H.263 standard, whereas the audio signal uses the adaptive multi-rate (AMR) codec, recommended for UMTS by the 3G Partnership Program (3GPP) (3GPP 2005b). This module provides the basic functionality for starting, pausing and stopping video signals acquisition and representation, as well as volume control for the microphone (capture) and the speakers (reproduction). Due to the fact that each participant in the conference receives a unique video signal, the system allows the user to select the particular video signal among all the users connected.

The high-resolution still image module obtains high quality images with a charge copled device (CCD) colour camera connected to the computer through an image acquisition card. This module includes options to preview the captured images and modify their main characteristics in real time: brightness, contrast, hue, etc. Captured

images can be stored and transmitted in different formats, with various qualities and compression levels. These images are sent automatically to the electronic whiteboard module of the remote users, allowing to select and mark fixed areas in a multi-collaborative fashion to facilitate a diagnostic clinical procedure.

Application Control

The MCU forwards the information generated by each medical service according to the presentation spaces defined using the control service. Each medical service has a presentation space associated with it that defines the way in which the information has to be transferred and its destination. The MCU simply forwards the information it receives, but has a special treatment for the audio, video, medical data, and control services. Regarding the Audio service, the MCU decodes the signal of each user, mixes it with the decoded signal of the other conference participants and codes the result in order to transfer a unique audio signal to each user (Figure 6). On the other hand, the MCU only forwards one video signal to each conference participant. The particular video signal forwarded to each user is selected by using the control service. Finally, the medical data service is similar to the video service: medical data are only generated in the remote location, whereas the other conference participants can only receive them.

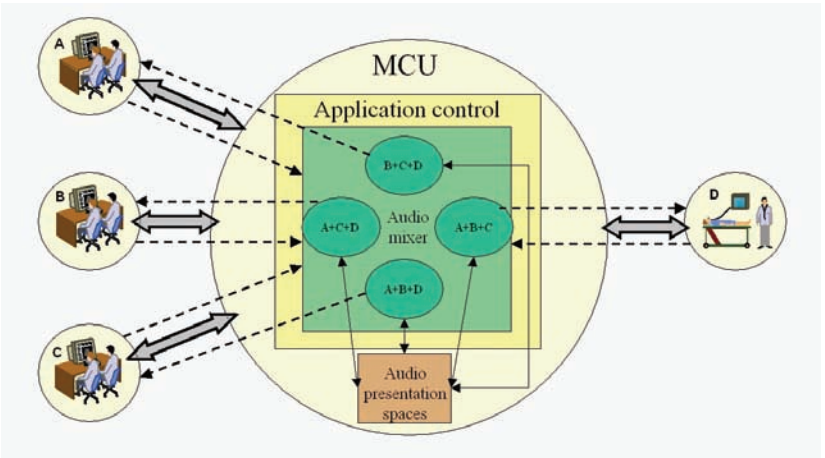
The 3G m-health system was adapted to the critical and emergency medical scenarios. In the first stages of its design, user requirements and functional specifications were established in collaboration with medical specialists, in order to create a portable and modular m-health system that could be easily integrated in any environment, using any underlying network technology capable of supporting IP multimedia services

3G M-HEALTH SYSTEM PERFORMANCE

In order to measure the 3G m-health system performance, several tests have been carried out using the system over 64 Kbps (at IP level) UMTS accesses. Table 2 presents the results about average IP-level bandwidth used by real-time network services.

As it can be observed, considering more audio samples per network packet reduces the used bandwidth, since transmission efficiency (information carried by each packet to total packet

Figure 6. Application control (audio presentation spaces)



size ratio) is increased. However, there is a limit in the number of audio samples per packet that can be used because more audio samples per packet yield more audio delay. For example, a more efficient transmission mode including four audio samples per packet every 80 ms causes four times the delay including only one audio sample per packet every 20 ms. Moreover, if an audio packet is lost, all the audio samples carried by it are lost and, therefore, a reduced number of audio samples per packet is more suitable to error-prone environments. Regarding the video user service, it is worth noting that the bandwidth shown in Table 2 can vary substantially with the movement of the video scene captured. Finally, the medical data service adapts well to the codec rate specified because medical data frame sizes are long enough to obtain a good transmission efficiency.

As it can be checked, the total bandwidth consumed by all real-time medical user services fits in a 64 Kbps UMTS channel, even when the most bandwidth-consuming codec rates and the lowest transmission efficiencies are used. If all medical user services are used (including non real-time services), lower codec rates should be selected. Thus, according to the previous discussions, the codec operation modes selected in this m-health system have been those highlighted in Table 2, achieving a reasonable trade-off between bandwidth, transmission efficiency, delay and loss ratio.

NEXT-GENERATION OF M-HEALTH SYSTEMS

It is evident that organizations and the delivery of health care are being underpinned by the advances in m-health technologies. In the future, home medical care and remote diagnosis will become common, check-up by specialists and prescription of drugs will be enabled at home and virtual hospitals with no resident doctors will be realized.

Hence, the deployment of emerging mobile and wireless technologies will face new challenges: inter-operability between heterogeneous networks (fourth-generation, 4G) and smart medical sensor design integrating sensing, processing, communications, computing, and networking.

With the aid of wireless intelligent medical sensor technologies, m-health can offer healthcare services far beyond what the traditional telemedical systems can possibly provide. The individual sensors can be connected wirelessly to a personal monitoring system using a wireless body area network (WBAN) and can be integrated into the user's clothing, providing wearable and ubiquitous m-health systems. A typical scenario

Table 2. Average IP-level bandwidth used by real-time user services

	Operation Mode		IP Bandwidth (Kbps)
	Samples/packet	Codec rate (Kbps)	
Audio	1	4.75	21.2
	1	12.2	28.8
	3	**4.75**	**10.5**
	3	12.2	18.1
	Frames per second		
Video	**5**		**16**
	10		24

	10		10.3

comprises of a WBAN system that communicates with cardiac implantable devices (pacemakers, defibrillators, etc.) and that is linked to the existing 3G infrastructure, achieving "Health Anytime, Anywhere" (Figure 7).

It is expected that 4G will integrate existing wireless technologies including UMTS, wireless LAN, Bluetooth, ZigBee, Ultrawideband, and other newly developed wireless technologies into a seamless system. Some expected key features of 4G networks are: high usability, support for multimedia services at low transmission cost and facilities for integrating services. 4G advances will make easier for mobile patients to interactively get the medical attention and advice they need. When and where is required and how they want it regardless of any geographical barriers or mobility constraints.

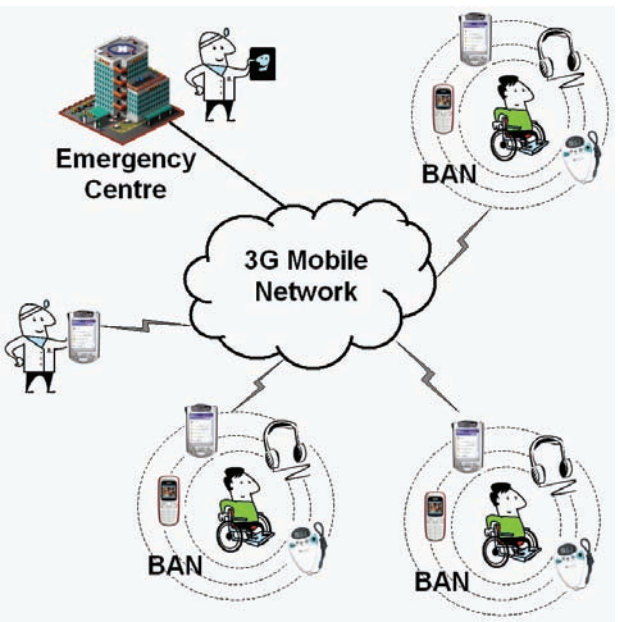
The concept of including high-speed data and other services integrated with voice services is emerging as one of the main points of future telecommunication and multimedia priorities with the relevant benefits to citizen-centered healthcare systems. The new wireless technologies will allow both physicians and patients to roam freely, while maintaining access to critical patient data and medical knowledge.

CONCLUSION

This chapter has presented a feasible 3G-based m-health system targeted specifically for critical and emergency medical scenarios. The system architecture is based on 3G networks and advanced signalling protocols (SIP/SDP) that allow the integration of real-time multimedia services over multiple access channels that support IPv4 and IPv6 interworking depending on current commercial UMTS releases.

The system has the following features: simultaneous transmission of real-time clinical data (including ECG signals, blood pressure, and blood oxygen saturation), videoconference, high-resolution still image transmission, and other facilities such as multi-collaborative whiteboard, chat, and Web access to remote databases. The system has been optimized specifically to operate

Figure 7. Typical WBAN-3G scenario



over 3G mobile networks using the most appropriate codecs. Evaluation results show a reliable performance over UMTS accesses (64 Kbps in the uplink).

Home telecare and chronic patient telemonitoring are other application areas in which this m-health system can be used, thus further work is currently undergone to adapt it and to evaluate its performance in each particular scenario.

KEY TERMS

4G: The fourth-generation (4G) is the continuation of the first, second, and third generations of mobile networks. It is a wireless access technology that provides high-speed mobile wireless access with a very high data transmission speed (2-20 Mbps) and enables users to be simultaneously connected to several wireless access technologies and seamlessly move between them in an all-IP environment. These access technologies can be any existing or future access technology. Smart antennas, low power consumption, and software-defined radio terminals will also be used to achieve even more flexibility for the user of 4G systems.

IMS: The IP multimedia subsystem (IMS) is a new open and standardized framework, basically specified for mobile networks, for providing Internet protocol (IP) telecommunication services. It offers a next generation network (NGN) multimedia architecture for mobile and fixed services, based on the session initiation protocol (SIP), and runs over the standard IP. It is used by telecom operators in NGN networks (combining voice and data in a single packet switched network), to offer network controlled multimedia services. The aim of IMS is not only to provide new services but to provide all the services, current and future, that the Internet provides. In addition, users have to be able to execute all their services when roaming as well as from their home networks. To achieve these goals the IMS uses IETF protocols. This is why the IMS merges the Internet with the cellular world; it uses cellular technologies to provide ubiquitous access and Internet technologies to provide new services.

IPv6: Internet protocol version 6 (IPv6) is the next generation protocol designed by the Internet Engineering Task Force (IETF) to replace the current version of the Internet protocol, IP version 4 (IPv4). Today's Internet has been using IPv4 for twenty years, but this protocol is beginning to become outdated. The most important problem of IPv4 is that there is a growing shortage of IPv4 addresses, which are needed by all new machines added to the Internet. IPv6 is the solution to several problems in IPv4, such as the limited number of available IPv4 addresses, and also adds many improvements to IPv4 in other areas. IPv6 is expected to gradually replace IPv4, with the two coexisting for a number of years during a transition period.

QoS: ITU-T recommendation E.800 defines the term quality of service (QoS) as "the collective effect of service performance which determines the degree of satisfaction of a user of the service." Service performance comprises of very different parts (security, operability, etc), so the meaning of this term is very broad. In telecommunications, the term QoS is commonly used in assessing whether a service satisfies the user's expectations. QoS evaluation, however, depends on functional components and is related to network performance via measurable technical parameters. A QoS-enabled network has the ability to provide better service (priority, dedicated bandwidth, controlled jitter, latency, and improved loss characteristics) to selected network traffic over various technologies.

SIP: The session initiation protocol (SIP) is a signalling protocol developed by the IETF intended for setting up multimedia communication sessions between one or multiple clients. It is currently the leading signalling protocol for voice over IP, and is one of the key components of the IMS multimedia architecture. The most important functions of SIP include name mapping and redirection (user location), capabilities negotiation during session setup, management of

session participants and capabilities management during the session.

Telemedicine: Telemedicine can be defined as the rapid access to shared and remote medical expertise by means of telecommunications and information technologies, no matter where the patient or the relevant information is located. Any application of information and communications technologies which removes or mitigates the effect of distance in healthcare is telemedicine. The terms e-health and tele-health are terms often interchanged with telemedicine.

Chapter 2.11
Service Provisioning in the IP Multimedia Subsystem

Adetola Oredope
University of Essex, UK

Antonio Liotta
University of Essex, UK

INTRODUCTION

The IP multimedia subsystem (IMS) specifies a service-centric framework for converged, all-IP networks. This promises to provide the long awaited environment for deploying technology-neutral services over fixed, wireless, and cellular networks, known as third generation (3G) networks. Since its initial proposal in 1999, the IMS has gone through different stages of development, from its initial Release 5 up to the current Release 7.

The IMS is also known as a domain for easily integrating and customising different services offering a new range of applications which aim at increasing the end-user experience. The IMS architecture will deploy both current and future Internet services on multi-access, 3G Networks (Camarillo & Garcâia-Martâin, 2006). These services include voice over IP (VoIP), instant messaging, video conferencing, online gaming, push-to-talk, and whiteboard sharing, to mention a few.

Service provisioning in the IMS offers the required mechanisms for execution, control, and integration of these services, including better and more efficient billing, accounting, quality of service (QoS), and interoperability across different administrative domains. All present and future Internet services will be deployed on a multi-access, all-IP overlay network via the IMS.

This version is based on the session initiation protocol (SIP) (Rosenberg et al., 2002) for its core functionality. SIP is used to create, modify and terminate sessions within the framework. SIP is also used to deliver sessions descriptions between SIP entities using the session description protocol (SDP) (Handley & Jacobson, 1998). The IMS provides an open interface for third-party services, such as the open service access (OSA) (3GPP-TS29.198, 2001) to be easily integrated, providing an opportunity for end-users to expe-

rience rich and personalized services (Liotta et al., 2002).

In this paper, the second section provides a brief description of the IMS network and service architectures required for deploying advanced IP services over converged networks. It also explains the IMS services capabilities standardization efforts and collaboration between the Third Generation Partnership Project (3GPP), 3GPP2, and the Open Mobile Alliance (OMA). The third section describes service provisioning in the IMS, providing the key elements for service execution (session and presence management), service quality control (quality control and billing), and service integration (open service access and converged billing), which are basic enablers for IMS service provisioning. The fourth section describes the future trends for service provisioning, outlining both academic and industrial opportunities in these areas. Finally, in the fifth section we draw key conclusions about service provisioning in the IMS.

IMS SERVICE ARCHITECTURE

IMS is based on a service oriented architecture (SOA) in which different services and applications from different vendors can easily communicate and be integrated to develop new services. In the IMS, service capabilities are standardised and not services. To help understand the IMS Service architecture, a brief description of the IMS network architecture (3GPP-TS23.002, 2006) and the standardisation service capabilities are first provided.

IMS Network Architecture

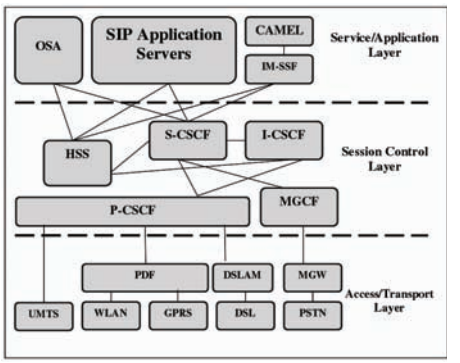
The IMS network architecture is built on a layered approach with open and standard interfaces to allow for seamless interconnection of standardized functions. In the IMS, nodes are not standardized, allowing vendors to combine as many functions as they wish into a particular node (Camarillo & Garcâia-Martâin, 2006). The horizontal layered approach of the IMS allows for lower layers to be transparent to the upper layers, enabling operators and service developers to use different underlying networks. This advantage allows interoperability and roaming. The IMS network architecture is divided in three basic layers as explained below (Figure 1).

A full description of the IMS network architecture can be found in 3GPP-TS23.002, 2006). From Figure 1, the Access Layer is an access-independent interface that allows users to connect to the IMS network via existing fixed or wireless networks, The session control layer is made up of SIP servers and proxies for controlling and managing sessions within the IMS. This is made up of the Proxy CSCF (P-CSCF), interrogating CSCF (I-CSCF), and the serving CSCF (S-CSCF). The service/application layer is also made up of different application servers for the execution of various IMS services and the provision of end user service logic.

Standardisation of Service Capabilities

Service capabilities are mechanisms needed to realise services within the IMS network and under the network control (3GPP-TS22.105, 2006). They are usually standardised to allow for service differentiation and system continuity. Service ca-

Figure 1. The IMS network architecture



pabilities include descriptions for bearer services, teleServices, and supplementary services.

The standardisation of service capabilities exists in other systems such as GPRS, but in the IMS, 3GPP, 3GPP2, and OMA are responsible for the standardisation of the service capabilities.

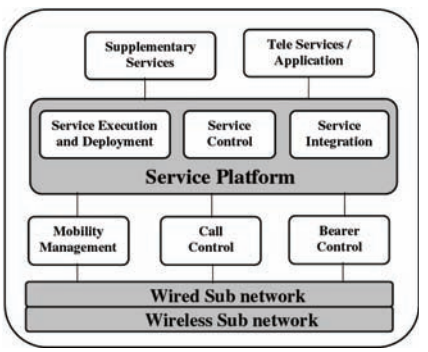
Some of OMA works are based on the IMS platform, and this leads to the proposals to extend the IMS in order to support additional requirements or service. This is the basis of the agreement between OMA, 3GPP, and 3GPP2 in which OMA generates the requirements for the IMS and the 3GPP and 3GPP2 extend the IMS to support the specified requirement (Camarillo & Garcâia-Martâin, 2006).

Due to this collaboration, OMA and 3GPP work on similar specifications at times and they aim to have compatible specifications. Examples of similar specifications being worked on by OMA and 3GPP include presence, messaging, and push-to-talk/push-over-cellular (PTT/PoC).

IMS Service Architecture

Based on the standardisation of service capabilities in Section 2.2, an IMS service architecture is developed to allow easy deployment and management of services. From the diagram, the Wired and Wireless sub networks provide interfaces that allow the IMS services to be transparent to the access network. These interfaces are explained below.

Figure 2. IMS service architecture (3GPP-TS22.105, 2006)



Bearer Control

Bearers allow information to be efficiently transferred to teleservices and applications via sub networks providing different levels of quality of service (QoS). They are usually classified with parameters such as “throughput,” “delay tolerance,” “maximum bit error rate,” “symmetry,” etc. (3GPP-TS22.105 2006). The bearer control plays a major role during interworking of functions and content adaptation.

Call Control

Call control allows the network operator to have total control of all information in the IMS network. This is achieved via a SIP proxy server known as a back-to-back user agent (B2BuA) placed in the signal and media path of end-to-end services between users. The B2BUA is based on an architecture that modifies the SIP messages (headers and bodies), generates and responds to requests (Camarillo & Garcâia-Martâin, 2006). The B2BUA allows the network operator full control of the traffic in the network, which in return allows for proper session management, resource reservation, internetwork billing, signalling interworking, protocol adaptation, and provision of integrated services. In the IMS, the B2BUA plays the major role of interconnecting the IMS with external networks (3GPP-TR29.962, 2005).

Mobility Management

Mobility is a key issue in the IMS because a large percentage of terminals in the network are mobile devices such as 3G phones, PDAs, laptops, and portable games. In fact, one of the most important challenges IP networks face is mobility support. Mobile IPv4 (MIPv4) (Perkins, 2002) and Mobile IPv6 (MIPv6) (Johnson, Perkins, et al., 2004) are the result of IETF mobility support efforts. These protocols enhance the network layer, so that IP hosts can change location while retaining their

communicating sessions. Due to the limitation of Mobile IP, the IMS manages mobility through GPRS, providing layer two tunnelling mechanisms. This allows for a successful handover to be made without the session or application breaking. Terminal Mobility also allows for roaming, which is led by the CSCF and the HSS to allow the access to the subscribed services either in a home or visited network (Camarillo & Garcâia-Martâin, 2006).

SERVICE PROVISIONING IN THE IMS

Why is IMS Service Provisioning Important?

The IMS aims to provide specialized end-user experience, better billing systems, enhanced security mechanisms, better mobility management (roaming), improved quality of service, and, most importantly, the integration of various services which cannot be found in present 3G networks. The IMS is viewed as a service-centric platform for endless development of new, rich, and exciting services. The IMS has put in place various mechanisms for the execution, control, and integration of theses services as shown in Figure 2. This process is known as service provisioning as explained in the following sections.

Service Execution and Deployment

The services offered in the IMS are hosted on application servers whereby some application servers may host multiple services. When a user registers with the network, the subscriber service profile (SSP) of the user is downloaded by the CSCF from the HSS. The SSP contains unique user-specific information such as:

- The services needed to be executed and the information on the order in which multiple services should be executed
- The location information of the application servers required to execute the services, and the order in which multiple services should be executed when they are on the same application server

The SSP information is used to deliver user-specific or personalized services to the end-users. These services are built on the various service enablers as explained below.

Presence Services

The presence service (PS) is the foundation of service provisioning in the IMS because it allows the collection of various forms of information on the characteristics of the network, users, and terminals. This service enabler allows users to subscribe for certain information (watchers) about other elements (presentities). Presentities can then decide to publish this information, which could include capabilities of terminals, locations, communication addresses, or user availability. Moreover, the IMS can also make the published information available to other services to allow for easy creation of new services and integration with existing services. For example, the IMS terminal plays the role of both a watcher and a presence user agent (PUA). The application server in the home network also plays the role of the presence server (PS), also known as presence agent (PA).

In order to allow for proper service execution in the IMS, the PA needs to get all relevant information from the necessary elements in the network, such as the home location register (HLR) in circuit networks, the gateway GPRS support node (GGSN) in GPRS networks, and the S-CSCF in the IMS network. This allows for proper service logics to be computed in order to deliver personalized services to the user.

Session Management

Sessions management is based on creation, modification, integration, and modification of conventional SIP messages as described in RFC-3261 (Rosenberg, Schulzrinne, et al., 2002). This allows end-users and operators to manage different sessions in the IMS, and also create new services. The CSCF (Figure 1) is at the heart of session management routing. The CSCF is basically a SIP server, and is divided in three major categories: P-CSCF, I-CSCF, and S-CSCF, as described earlier in the second section. IMS also supports SIP extensions in which "required" and "supported" headers are used. This also allows for the creation of new services such as presence (Roach, 2002) and instant messaging (Campbell, Rosenberg, et al., 2002).

The IMS terminal can send a REGISTER request via the P-CSCF to the I-CSCF and then the S-CSCF. If the registration is successful, a 200 OK message is replied back to the terminal via the same route. Once registration is complete, sessions to User Agents can be easily managed by invoking new or existing services using various SIP messages such as INVITE, SUBSCRIBE, NOTIFY, and PRACK to mention a few.

Application Servers and Gateways

As described earlier in the second section, application servers are used to host and execute the services used in the IMS network. An application server can host more than a single service. There are three different application servers: namely, the SIP application servers for IMS services, the open service access-service capability server (OSA-SCS), a gateway to execute OSA in the IMS, and the IMS switching function (IM-SSF)—a gateway between the IMS and CAMEL, which is deployed in GSM networks.

Gateways, on the other hand, are used to interconnect other standardized formats to the standards supported in the IMS. Examples include: the Media Gateway, which interfaces the media plane in the circuit-switched network, converting between PCM and RTP. Also, the media gateway controller function (MGCF) is used as call-control protocol conversion between SIP and ISUP (integrated services digital network user part). The latter defines the procedures used to setup, manage, and release trunk circuits that carry voice and data calls over the public switched telephone network (PSTN).

Group List Management

This enabler is part of the presence service (PS). It allows users to create and manage network-based groups using definitions of the services deployed in the IMS. It allows the users to have access to information on, and receive notifications about, the groups. This is used in the development of buddy lists, contact lists, blogs, public/private chat groups, and new services where identities are required. This enabler can also be used for roaming purposes, where the users need access to the usual customized services.

IMS Service Control

Service control (Figure 2) plays a major role in IMS service provisioning due to the fact that it allows the synchronization needed for session establishment and quality of service (QoS) management. In this way, the end-users can have a predictable experience at a reasonable charge as compared to present 3G networks. Service control also allows the service platform to be reusable by allowing proper control and management of complex functions such as service filtering, triggering, and interaction. The main enablers for service control are: quality control, mobility management, security, and billing, as described below.

Quality Control

Quality control in the IMS is described in terms of end-to-end QoS, aiming at a predictable user experience. All steps are taken to ensure that all necessary policies are enforced to guarantee the assigned QoS (Dong, 2005).

In order to allow end-to end QoS, QoS is managed within each domain. The IMS supports various end-to-end QoS models in which the basic reservation protocols are used. The terminals can use either the Integrated Services—including the resource reservation protocol (RSVP)—or differentiated services (DiffServ) codes, as long as they are mapped to the DiffServ codes in the network (Borosa, Marsic, et al., 2003). The link-layer resource reservation is made over a policy decision point (PDP) context and is assigned to the appropriate DiffServ code point (DSCP), which is possibly in the same domain, and is then sent into the DiffServ-enabled Network.

Security

Security in the IMS is based on the IP security protocol (IPSec) (Kent & Atkinson, 1998) in which extensions have been created to manage IPSec security associations for SIP in the IMS. IPSec is also the preferred choice for IPv6. It is an extension of IP which allows security to be removed from the network and placed on the endpoints by applying encryption to either the entire IP payload (tunnel mode) or only to the upper-layer protocols of the IP payload (transport mode). IPSec allows for security services such as data integrity protection, data origin authentication, anti-replay protection, and confidentiality, also offering protection to the upper layers. This allows the security mechanism in the IMS to be divided into Access Security (for users and the network) and Network Security (for the protection of traffic between network elements).

Billing

The IMS is built on multimedia messages requiring large file transfers to ensure good quality. By contrast to the billing approach used in conventional Telecom systems, in the IMS the end-users are charged for the services offered rather than by the bytes transferred. This allows, for example, chat sessions to be charged based on duration rather than by the amount of messages transferred. Each session carries a unique IMS charging identifier (ICID) per session and also an inter-operator identifier (IOI) defining the originating and termination networks. There are basically two categories of billing, which are offline for post-paid users, and online charging for prepaid users.

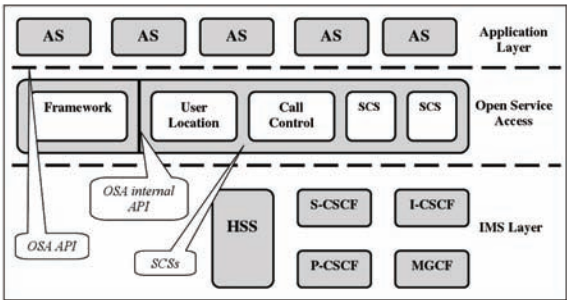
IMS Service Integration

Service integration in the IMS is the element of service provisioning that allows new and rich services to be easily developed. This also allows for an inexpensive integration of both real time and non-real time services to easily construct more complex and attractive "bundled services." The basic enablers for service integration are explained below.

Open Service Architecture (OSA)

The OSA is the defined architecture that allows operators and third-party service providers to make use of the underlying network functionalities through the standardised open standard interface as described in the second section. The OSA also makes the application independent of the underlying network technology (Figure 3) (3GPP-TS23.127 2002). Service capability servers (SCS) provide the application with service capability features (SCF), which are abstractions from the underlying network functionality. SCS implement SCF and interact with the core network. Example SCF are call control, session control, terminal

Figure 3. OSA architecture



capability, charging, account management, and user location.

The framework provides applications with basic mechanisms that enable them to make use of service capabilities in the network. Example framework functions include service discovery and registration, authentication, trust and security management, and service factory.

The main aim of OSA is to provide an extensible and scalable architecture that allows for inclusion of new service capability features and SCS with a minimum impact on the applications, using the OSA interface.

While SCS provide a first, low-level of support aimed at facilitating application development, the application layer offers a second, higher-level of support aimed at speeding up application development. Applications are implemented in one or more application servers (AS), which hide distributional aspects and offer a standard programming environment, application-oriented APIs (e.g., JAIN), and reusable components (e.g., Java Beans) that realise SCF functionality.

Converged Billing

The concept of converged billing allows the operator to charge on the basis of service, content, volume, or an integration of the services in a prepaid or post-paid manner (the modes of payment were discussed under billing earlier on). Converged billing also allows the user to use the operator as their converging point for all their billing, even if some of their services are offered by third-party service providers. This is possible via the single sign on feature in the IMS that allows the user to register with the network, and does not need any form of re-authentication for subsequent services. This gives users the assurance that all their billing is handed by a centrally secure source and gives them enough confidence to spend on the services.

FUTURE TRENDS

The IMS core network architecture is being deployed by various vendors and operators. A lot of end-to-end interoperability testing has been carried out, for instance by Nokia and NEC (Nokia & NEC, 2004). IBM and Swisscom have conducted proof-of-concept tests (IBM, 2006). Also, new services are staring to appear, for instance the proposed mobile gaming architecture (Akkawi, Schaller, et al., 2004) and the platform for mobile TV (Faria, Henriksson, et al., 2006). There also are various tools available to develop IMS services. An example is the Java API for integrated networks (JAIN) in which various expert groups provide reusable APIs that are easily assessed.

The enormous interest surrounding the IMS indicates that this may really become the standard framework for deploying advanced, ubiquitous services over converged, all-IP networks, i.e., the "domain of services." However, not all research areas have been fully explored yet, especially in the area of distributed session management. Many approaches have been developed to eliminate (or reduce) the number of centralized servers from the IMS, aiming at a better level of scalability. Another promising area of research is looking at the deployment of peer-to-peer services in the IMS (Liotta, 2005). This requires coming up with solutions as to how SIP sessions can be managed via distributed signalling protocols (Bryan, 2005).

CONCLUSION

Service provisioning in the IMS enables network operators, service providers, and end-users to benefit from the advantages of an open architecture which relies on a solid framework for service execution, control, and integration. These provisioning enablers include presence and location services, quality control, security, and billing (to mention a few).

The IMS as a whole has great potential and has been developing rapidly over the years, offering a solution to the all-IP vision of rich, multi-access multimedia services accessible anywhere, at any time, with the required quality, and at the right price.

The IMS is now widely considered as the future service-centric platform of preference, although several researchers are still arguing that the benefits of IMS come with a high cost linked to its layered approach (complexity). Only a large-scale deployment of the IMS and a wide adoption by operators and service providers will allow a full assessment of its benefits and shortcomings. These will hopefully be unveiled in the next few years.

INTRODUCTION

Internet is a heterogeneous network environment and the network resources that are available to real time applications can be modified very quickly. Real time applications must have the capability to adapt their operation to network changes. In order to add adaptation characteristics to real time applications, we can use techniques both at the network and application layers. Adaptive real time applications have the capability to transmit multimedia data over heterogeneous networks and adapt media transmission to network changes. In order to implement an adaptive multimedia transmission application, mechanisms to monitor the network conditions, and mechanisms to adapt the transmission of the data to the network changes must be implemented.

Today, the underlying infrastructure of the Internet does not sufficiently support quality of service (QoS) guarantees. The new technologies, which are used for the implementation of networks, provide capabilities to support QoS in one network domain but it is not easy to implement QoS among various network domains, in order to provide end-to-end QoS to the user. In

addition, some researchers believe that the cost for providing end-to-end QoS is too big, and it is better to invest on careful network design and careful network monitoring, in order to identify and upgrade the congested network links (Diot, 2001).

In this article, we concentrate on the architecture of an adaptive real time application that has the capability to transmit multimedia data over heterogeneous networks and adapt the transmission of the multimedia data to the network changes. Moreover in this article, we concentrate on the unicast transmission of multimedia data.

BACKGROUND

The subject of adaptive transmission of multimedia data over networks has engaged researchers all over the world. During the design and the implementation of an adaptive application special attention must be paid to the following critical modules:

- The module, which is responsible for the transmission of the multimedia data
- The module, which is responsible for monitoring the network conditions and determines the change to the network conditions
- The module, which is responsible for the adaptation of the multimedia data to the network changes
- The module, which is responsible for handling the transmission errors during the transmission of the multimedia data

A common approach for the implementation of adaptive applications is the use of UDP for the transmission of the multimedia data and the use of TCP for the transmission of control information (Parry & Gangatharan, 2005; Vandalore, Feng, Jain, & Fahmy, 1999). Another approach for the transmission of the multimedia data is the use of RTP over UDP (Bouras & Gkamas, 2003; Byers et al., 2000). Most adaptive applications use RTP/RTCP (real time transmission protocol / real time control transmission protocol) (Schulzrinne, Casner, Frederick, & Jacobson, 2003) for the transmission of the multimedia data. The RTP protocol seems to be the de facto standard for the transmission of multimedia data over the Internet and is used both by mbone tools (vit, vat, etc.) and ITU H.323 applications. In addition RTCP offers capabilities for monitoring the transmission quality of multimedia data.

For the implementation of the network monitoring module, a common approach is to use the packet loss as an indication of congestion in the network (Bouras et al., 2003; Byers et al., 2000). One other approach for monitoring the network conditions is the use of utilization of the client buffer (Rejaie, Estrin, & Handley, 1999; Walpole et al., 1997). An important factor that can be used for monitoring the network conditions, and especially for indication of network congestion, is the use of delay jitter during the transmission of the multimedia data.

For the implementation of the adaptation module, some common approaches are the use of rate shaping (Byers et al., 2000; Bouras et al., 2003), the use of layered encoding (Rejaie et al., 1999), the use of frame dropping (Walpole et al., 1997) or a combination of the previous techniques (Ramanujan et al., 1997). The implementation of the adaptation module depends on the encoding method that is used for the transmission of the multimedia data. For example, in order to use the frame dropping technique for the adaptation of a MPEG video stream, a selective frame dropping technique must be used, due to the fact that MPEG video uses inter-frame encoding and some frames contain information relative to other frames. In Vandalore et al. (1999), a detailed survey of application level adaptation techniques is given.

It is important for adaptive real time applications to have "friendly" behavior to the dominant transport protocols (TCP) of the Internet (Floyd & Fall, 1998). In Widmer et al. (2001), a survey

on TCP-friendly congestion control mechanisms is presented.

ADAPTIVE TRANSMISSION OF MULTIMEDIA DATA OVER THE INTERNET

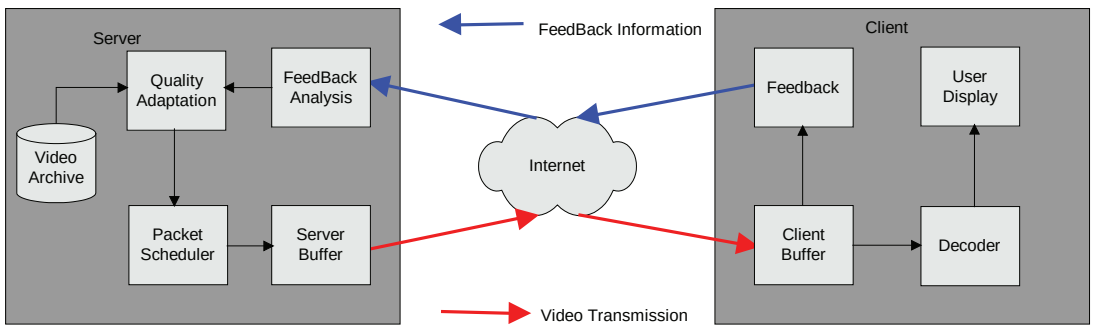
The Architecture of an Adaptive Streaming Application

This section presents a typical architecture for an adaptive streaming application, based on the client server model. Figure 1 displays the architecture of such an adaptive streaming application.

The server of the adaptive streaming architecture consists of the following modules:

- **Video archive:** Video archive consists of a set of hard disks in which the video files are stored. The adaptive streaming application may support various video formats (for example MPEG, JPEG, H.263, etc.). It is possible for one video file to be stored in the video archive in more than one format in order to serve different target user groups. For example, it is possible to store the same video in MPEG format in order to serve the users of the local area network (who have faster network connection with the server) and in H.263 format in order to serve distant users with slow network connections. In this article, we do not investigate the problem of video storage in video archives in order to achieve the optimal performance of the server.
- **Feedback analysis:** This module is responsible for the analysis of feedback information from the network. The role of this module is to determine the network condition mainly based on packet loss rate and delay jitter information, which are provided by RTCP receiver reports. After the examination of network condition, the feedback analysis module informs the quality adaptation module, in order to adapt the transmission of the video to current network conditions.
- **Quality adaptation:** It is responsible for the adaptation of the video transmission quality in order to match with the current network conditions. This module can be implemented using various techniques (rate shaping, layered encoding, frame dropping, etc.).
- **Packet scheduler/Server buffer:** This module is responsible for the encapsulation of multimedia information in the RTP packets. In addition, this module is responsible for the transmission of the RTP packets in the network. In order to smooth accidental problems to the transmission of the multimedia data from the server to the network, an output buffer is used on the server.

Figure 1. System architecture



The client of the adaptive streaming architecture consists of the following modules:

- **Client buffer:** The use of the buffer on the client for the implementation of streaming applications is very important. The client application stores the incoming data to the buffer before starting to present data to the user. The presentation of the multimedia data to the user starts only after the necessary amount of the data is stored in the buffer. The capacity of the client buffer depends to the delay jitter during the transmission of the multimedia data. In any case the capacity of the client buffer must be greater than the maximum delay jitter during the transmission of the data (we suppose that we measure the buffer capacity and the delay jitter in the same units, e.g. in seconds).
- **Feedback:** This module is responsible of monitoring the transmission quality of the data and informing the server. The monitoring of the transmission quality is based on RTCP receiver reports that the client sends to the server. RTCP receiver reports include information about the packet loss rate and the delay jitter during the transmission of the data. With the previous information, the feedback analysis module of the server determines the network's condition.
- **Decoder:** This module reads the data packets from the client buffer and decodes the encoded multimedia information. Depending on the packet losses and the delay during the transmission of the packets, the quality of the multimedia presentation can vary. The decoding and the presentation of the multimedia data can stop, if the appropriate amount of data does not exist in the buffer.
- **User display:** It is responsible for the presentation of the multimedia data to the user.

In the following paragraphs, we give a detailed description of the most important modules of the previously described architecture.

Transmission of Multimedia Data

The transmission of the multimedia data is based on the protocols RTP/RTCP. The protocol RTP is used for the transmission of the multimedia data from the server to the client and the client uses the RTCP protocol, in order to inform the server of the transmission quality.

The RTP/RTCP protocols have been designed for the transmission of real time data like video and audio. Although the RTP/RTCP protocols were initially designed for multicast transmission, they were also used for unicast transmissions. RTP/RTCP can be used for one-way communication like video on demand or for two-way communication like videoconference. RTP/RTCP offers a common platform for the representation of synchronisation information that real time applications needs. The RTCP protocol is the control protocol of RTP. The RTP protocol has been designed to operate in cooperation with the RTCP protocol, which provides information about the transmission quality.

RTP is a protocol that offers end to end transport services with real time characteristics over packet switching networks like IP networks. RTP packet headers include information about the payload type of the data, numbering of the packets and timestamping information.

RTCP offers the following services to applications:

- **QoS monitoring:** This is one of the primary services of RTCP. RTCP provides feedback to applications about the transmission quality. RTCP uses sender reports and receiver reports, which contain useful statistical information like total transmitted packets, packet loss rate and delay jitter during the transmission of the data. This statistical

information is very useful, because it can be used for the implementation of congestion control mechanisms.

- **Source identification:** RTCP source description packets can be used for identification of the participants in a RTP session. In addition, source description packets provide general information about the participants in a RTP session. This service of RTCP is useful for multicast conferences with many members.
- **Inter-media synchronisation:** In real time applications, it is common to transmit audio and video in different data streams. RTCP provides services like timestamping, which can be used for inter-media synchronisation of different data streams (for example synchronisation of audio and video streams).

More information about RTP/RTCP can be found in RFC 3550 (Schulzrinne et al., 2003).

Feedback from the Network

The presentation quality of real time data depends on the packet loss rate and the delay jitter during the transmission over the network. In addition, packet losses or rapid increases of delay jitter may be considered as an indication of problems during the transmission of data over the network. In such a case, the adaptive streaming application must adapt the transmission of the data in order to avoid phenomenon like network congestion. Real time applications have upper bounds to the packet loss rate and to the delay jitter. If packet loss rate or jitter gets to be over these upper bounds, the transmission of real time data can not be continued.

Packet loss rate is defined as the fraction of the total transmitted packets that did not arrive at the receiver. Usually the main reason of packet losses is congestion.

It is difficult to define delay jitter. Some researchers define delay jitter as the difference between the maximum and the minimum delay during the transmission of the packets for a period of time. Some other researchers define delay jitter as the maximum difference between the delay of the transmission of two sequential packets for a period of time. According to RFC 3550 (Schulzrinne et al., 2003), delay jitter is defined to be the mean deviation (smoothed absolute value) of the difference in packet spacing at the receiver compared to the sender for a pair of packets. This is equivalent to the difference in the "relative transit time" for the two packets. The relative transit time is the difference between a packet's timestamp and the receiver's clock at the time of arrival. If s_i is the timestamp from packet i and R_i is the time of arrival for this packet, then for two packets i and j, D is defined as: $D(i,j) = (R_j - R_i) - (S_j - S_i) = (R_j - S_j) - (R_i - S_i)$. The delay jitter is calculated continuously as each packet arrives, using the difference for that packet and the previous packet, according to the following formula:

$$J_i = J_{i-1} + (|D(i-1, j)| - J_{i-1})/16$$

The previous formula states that the new value of delay jitter depends on the previous value of the delay jitter and on a gain parameter, which gives good noise reduction.

Delay jitter occurs when sequential packets encounter different delays in the queue of the network devices. The different delays are related to the serve model of each queue and the cross traffics in the transmission path.

Sometimes delay jitter occurs during the transmission of real time data, which does not originate from the network but is originated from the transmission host (host included delay jitter). This is because during the encoding of the real time data, the encoder places a timestamp in each packet, which gives information about the time that the packet's information, must be presented to the receiver. In addition, this timestamp is used for the calculation of the delay jitter during the transmission of the real time data. If a notable

time passes from the encoding of the packet and transmission of the packet in the network (because the CPU of the transmitter host is busy) the calculation of the delay jitter is not valid. Host included delay jitter can lead to erroneous estimation for the network conditions.

We can conclude that delay jitter can not lead to reliable estimation of network condition by itself. Delay jitter has to be used in combination with other parameters, like packet loss rate, in order to make reliable estimations of the network conditions. In Bouras et al. (2003), it is shown that the combination of packet loss rate and delay jitter can be used for reliable indication of network congestion.

Quality Adaptation

Quality adaptation module is based on the rate shaping technique. According to the rate shaping technique, if we change some parameters of the encoding procedure, we can control the amount of the data that the video encoder produces (either increase or decrease the amount of the data) and as a result, we can control the transmission rate of the multimedia data.

The implementation of rate shaping techniques depends on the video encoding. Rate shaping techniques change one or more of the following parameters:

- **Frame rate:** Frame rate is the rate of the frames, which are encoded by video encoder. Decreasing the frame rate can reduce the amount of the data that the video encoder produces but will reduce the quality.
- **Quantizer:** The quantizer specifies the number of DCT coefficients that are encoded. Increasing the quantizer decreases the number of encoded coefficients and the image is coarser.
- **Movement detection threshold:** This is used for inter-frame coding, where the DCT is applied to signal differences. The movement detection threshold limits the number of blocks which are detected to be "sufficiently different" from the previous frames. Increasing this threshold decreases the output rate of the encoder.

Error Control/Packet Loss

The packet loss rate is depends on various parameters and the adaptive transmission applications must adapt to changes of packet losses. Two approaches are available to reduce the effects of packet losses:

- **APQ (Automatic Repeat Request):** APQ is an active technique where the receiver and ask the sender to retransmit some lost packets.
- **FEC (Forward Error Correction):** FEC is a passive technique where the sender transmits redundant information. This redundant information is used by the receiver to correct errors and lost packets.

FUTURE TRENDS

The most prominent enhancement of the adaptive real time applications is the use of multicast transmission of the multimedia data. The multicast transmission of multimedia data over the Internet has to accommodate clients with heterogeneous data reception capabilities. To accommodate heterogeneity, the server may transmit one multicast stream and determine the transmission rate that satisfies most of the clients (Byers et al., 2000; Rizzo, 2000; Widmer et al., 2001), and may transmit multiple multicast streams with different transmission rates and allocate clients at each stream or may use layered encoding and transmit each layer to a different multicast stream (Byers et al., 2000). An interesting survey of techniques for multicast multimedia data over the Internet is presented by Li, Ammar, and Paul (1999).

Single multicast stream approaches have the disadvantage that clients with a low bandwidth link will always get a high-bandwidth stream if most of the other members are connected via a high bandwidth link and the same is true the other way around. This problem can be overcome with the use of a multi-stream multicast approach. Single multicast stream approaches have the advantages of easy encoder and decoder implementation and simple protocol operation, due to the fact that during the single multicast stream approach there is no need for synchronization of clients' actions (as is required by the multiple multicast streams and layered encoding approaches).

The subject of adaptive multicast of multimedia data over networks with the use of one multicast stream has engaged researchers all over the world. During the adaptive multicast transmission of multimedia data in a single multicast stream, the server must select the transmission rate that satisfies most the clients with the current network conditions. Three approaches can be found in the literature for the implementation of the adaptation protocol in a single stream multicast mechanism: equation based (Rizzo, 2000; Widmer et al. (2001), network feedback based (Byers et al., 2000), or based on a combination of the previous two approaches (Sisalem & Wolisz, 2000).

CONCLUSION

Many researchers urge that due to the use of new technologies for the implementation of the networks, which offer QoS guarantees, adaptive real time applications will not be used in the future. We believe that this is not true and adaptive real time applications will be used in the future for the following reasons:

- Users may not always want to pay the extra cost for a service with specific QoS guarantees when they have the capability to access a service with good adaptive behaviour.
- Some networks may never be able to provide specific QoS guarantees to the users.
- Even if the Internet eventually supports reservation mechanisms or differentiated services, it is more likely to be on per-class than per-flow basis. Thus, flows are still expected to perform congestion control within their own class.
- With the use of the differential services network model, networks can support services with QoS guarantees together with best effort services and adaptive services.

KEY TERMS

Adaptive Real Time Applications: Adaptive real time applications are application that have the capability to transmit multimedia data over heterogeneous networks and adapt media transmission to network changes.

Delay Jitter: Delay jitter is defined to be the mean deviation (smoothed absolute value) of the difference in packet spacing at the receiver compared to the sender for a pair of packets.

Frame Rate: Frame rate is the rate of the frames, which are encoded by video encoder.

Movement Detection Threshold: The movement detection threshold is a parameter that limits the number of blocks which are detected to be "sufficiently different" from the previous frames.

Multimedia Data: Multimedia data refers to data that consist of various media types like text, audio, video, and animation.

Packet Loss Rate: Packet loss rate is defined as the fraction of the total transmitted packets that did not arrive at the receiver.

Quality of Service (QoS): Quality of service refers to the capability of a network to provide better service to selected network traffic.

Quantizer: Quantizer specifies the number of DCT coefficients that are encoded.

RTP/RTCP: Protocol which is used for the transmission of multimedia data. The RTP performs the actual transmission and the RTCP is the control and monitoring transmission.

ABSTRACT

This chapter focuses on the key challenges in the design of multimedia-based scalable techniques for threat management and security of information infrastructures. It brings together several multimedia technologies and presents a conceptual architectural framework for an open, secure distributed multimedia application that is composed of multiple domains employing different security and privacy policies and various data analysis and mining tools for extracting sensitive information. The challenge is to integrate such disparate components to enable large-scale multimedia applications and provide a mechanism for threat management. The proposed framework provides a holistic solution for large-scale distributed multi-domain multimedia application environments.

INTRODUCTION

Security of information infrastructures, both in public or private sectors, is vital to overall national security goals. Such infrastructures provide capabilities for gathering, managing, and sharing vital information among numerous organizations that can form large e-enterprises and generally interoperate in the form of a federation of autonomous domains (Joshi, Ghafoor, Aref, & Spafford, 2001; Thuraisingham, 2003). Information shared among multiple domains can come in various forms including text, audio, video, and images which can increase the complexity of security and privacy management. The key security challenges include integration of diverse security policies of collaborating organizations into a coherent capability for protecting information and using collaborative knowledge for detecting and responding to any emerging threats. In addition, information privacy is generally an overriding concern (Adams & Sasse, 1999). Furthermore, a plethora of data analysis and mining tools have emerged that cyber defenders can use to extract sensitive information from public and private multimedia applications and detect patterns and activities indicating potential threats to an infrastructure. Thus, two key challenges to the design of multimedia-based scalable techniques for threat management and security of information infrastructures are *data mining* and *security*, which we briefly overview in the next section.

KEY ISSUES IN DATA MINING AND MULTIMEDIA SECURITY

Multimedia Data Analysis and Mining

Emerging multimedia applications require large-scale integration, mining, and analysis of multimedia data that is generally distributed over multiple security domains. Most of these applications use sensitive information for identifying complex threat actions that cannot be detected via real-time monitoring as such actions can take place over relatively long timeframes. Examples of such applications include detecting the spread of an epidemic and monitoring deterioration of the environment. However, today, data no longer appears in the text form only. Instead, the information from different sources may be in the form of text, image, video, audio, or multimedia documents consisting of several multimedia objects that are tightly synchronized both in space and time (Little & Ghafoor, 1990). Unlike mining the relational data, multimedia data mining is a more complex issue due to the sheer volume and heterogeneous characteristics of the data and the spatial and/or temporal relationships that may exist among multimedia data objects.

Mining multimedia data has recently been addressed in the literature (Chen et al., 2003a; Chen et al., 2004; Thuraisingham, 2003). Most of the existing approaches, however, provide limited capabilities in terms of content analysis and generally do not exploit correlations of multiple data modalities originating from diverse sources and/or sensors. Real-time mining and correlating of multi-modality data from distributed sources and using security-oriented spatio-temporal knowledge can assist in identifying potential threats and ensuring security of large-scale infrastructures (e.g., in command and control environments). In a broader perspective, both *long-ranged* and *real-time* data analysis and mining techniques are needed to allow multi-level content analysis and representation of multimedia data at different levels of resolution to facilitate information classification that has security and privacy implications.

Security Policy and Privacy Management

The multi-modality nature of data and the unique synchronization and *quality of service* (QoS) requirements of multimedia information systems

makes its protection uniquely challenging. These challenges are briefly discussed below.

Content-based Context-aware Access. An application may require controlled access to information based on the sensitivity level of information content, time, location, and other contextual information obtained at the time the access requests are made. For example, in the health care industry, selective content-based access to patient information should be given to physicians, insurance providers, and so forth. Furthermore, a non-primary physician of a patient, who normally does not have access to the patient's records, may need to be allowed access in a *life-threatening* situation.

Heterogeneity of Subjects and Objects. For multimedia applications, heterogeneity implies the diversity of object and subject types. Object heterogeneity implies different types of media, abstract concepts, or knowledge embodied in the information that needs to be protected. For instance, in a digital library system, it is desirable to provide access based on concepts rather than on individual objects. For example, a user may want to access information related to concept *Juvenile Law*. Subject heterogeneity implies that the users have diverse activity profiles, characteristics, and/or qualifications that may not be known *a priori*, which can complicate the specification of access control requirements.

- **Privacy:** Because of the richness of information content of multimedia data, privacy concerns are exacerbated in a multimedia environment (Adams & Sasse, 1999). For instance, a perfectly harmless video sequence of a conference presentation may show a certain behavior of a person (e.g., sleeping during the presentation) in the audience which may result in adversely affecting his/her status if it is viewed by his employer.
- **Dynamically Changing Access/Privacy Requirements:** Access control and privacy requirements in Web-based multimedia applications are inherently dynamic in nature, as the information contents may change frequently. Powerful and flexible access control and privacy models are needed to capture dynamically changing access and privacy parameters in an evolving system.
- **Integration of Access and Privacy Policies:** As multimedia information often exists in distributed heterogeneous administrative domains, there is a growing challenge of developing efficient integration and evolution management tools and techniques for inter-domain access control policies for distributed multimedia applications. Mechanisms are required to support careful analysis of security policies for the multi-domain environment and for mapping multimedia content parameters associated with the *security clusters* that data mining tools may generate to define content-based access control and privacy policies. Situations can also arise when the existing static security policies, both local and global, may not provide sufficient safeguards against emerging threat scenarios and require changes as a scenario unfolds based on the information extracted from newly mined data. In such situations, real-time analysis of dynamic access control policies is required to prevent any potential security breaches in multimedia applications. In such an integrated environment, another key challenge is to efficiently manage the evolution of local and global information classifiers, and security and privacy policies.

Central to these problems is a crucial issue of uniform representation, interchange, sharing, and dissemination of information content over an open, multi-domain environment. Due to the multi-modality nature of multimedia data, the

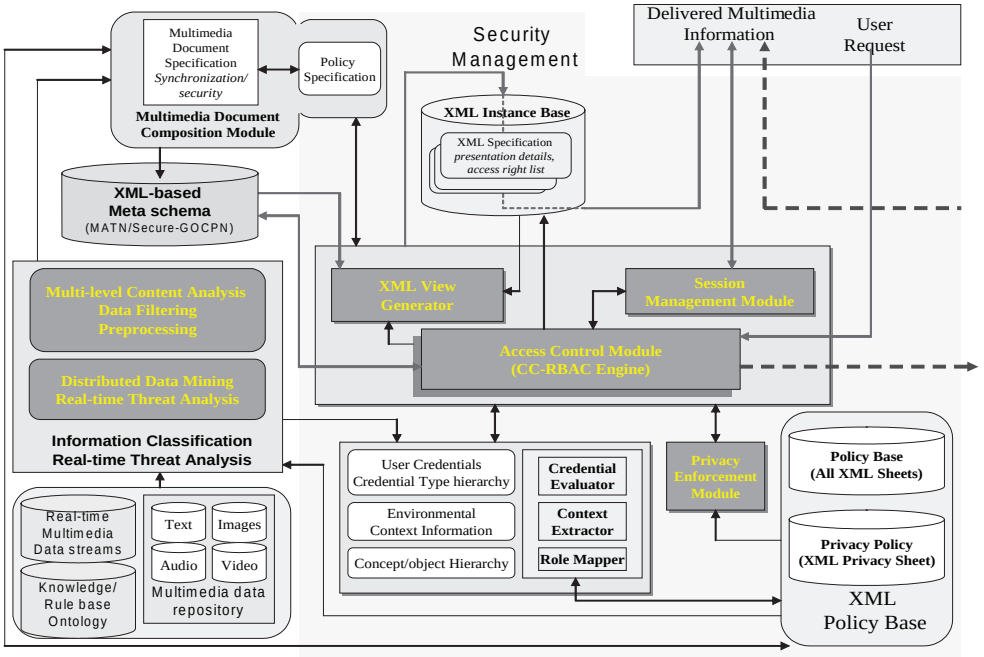
real-time constraints, and heterogeneity of distributed domains, an integrated solution is needed to address the above-mentioned data mining, and security and privacy challenges. To meet these requirements, the integration of several technologies such as data mining, distributed multimedia systems, access control, and privacy models and mechanisms is needed. *EXtensible Markup Language* (XML) (Bertino, Castano, Ferrari, & Mesiti, 1999; Damiani, di Vimercati, Paraboschi, & Samarati, 2002) has emerged as a promising technology for addressing such a fundamental issue of information representation, interchange, sharing, and dissemination (Thuraisingham, Clifton, & Maurer, 2001). XML supports a rich set of features including user-defined tags, nested document structures, and document schemata (Bertino et al., 1999; Bertino, Castano, & Ferrari, 2001; Damiani et al., 2002). Several emerging XML-related technologies, including *Resource Definition Framework* (RDF), *DARPA Agent Markup Language + Ontology Inference Layer* (DAML+OIL), and *Web Ontology Language* (OWL), provide support for integrating information from different domains by facilitating semantic matching of elements (Hunter, 2003; McGuinness, Fikes, Hendler, & Stein, 2002). Moving Pictures Experts Group's MPEG-21 is an open multimedia standard that supports multimedia content delivery and consumption (Burnett et al., 2003). MPEG-21, however, does not capture flexible access control requirements outlined earlier. To the best of our knowledge, no prior research has addressed the above issues in a unified manner by integrating various technologies for developing a secure distributed multi-domain multimedia environment, although several researchers have addressed some of these issues. In this chapter, we discuss various challenges and present a conceptual framework for a scalable secure multi-domain multimedia information system that addresses these challenges.

CONCEPTUAL SYSTEM ARCHITECTURE

Various functional components of the conceptual architecture for a single domain multimedia environment are depicted in Figure 1. The *XML-based Multimedia Document Composition Module* (XDCM) provides an interface for composing XML schemata for multimedia information and policy documents and includes *Policy Composition Interface*. Access control and privacy policy documents are stored in the *XML Policy Base* (XPB). The *Access Control and Privacy Enforcement Modules* (ACM, PEM) constitute the key enforcement modules. The ACM employs a content-based context-aware RBAC engine, extracts the policy information from the XPB, and interacts closely with the *XML View Generator* (XVG) module to produce the authorized presentation schema for a user. Authorized XML instances are further checked against privacy policies by the PEM to ensure that privacy policies are enforced. The *Session Management Module* (SMM) is responsible for monitoring the real-time activities of the multimedia presentation, as well as dynamic access constraints, and interacts with ACM and XVG to update active XML views.

The *Information Classification and Real-time Threat Analysis Module* (ICRTAM) is responsible for the classification of multimedia data and threat analysis based on real-time multimedia data streams. The clusters that it generates are organized in a hierarchy. The *Role Mapper* generates concept roles for these clusters and creates required policy sheets that define access rules and privacy protection requirements. The *Credential Evaluator* (CEv) module evaluates the credentials presented by the ACM. With the help of the *Role Mapper*, it maps the credentials to a role as defined by the access rules. The *Context Extractor* (CEx) evaluates the contextual information and sends the results to the ACM so it can evaluate context-based dynamic policies. The multimedia data repository constitutes the physical objects present in the system that are used to generate the XML multimedia object *meta-*

Figure 1. Conceptual design of a single domain multimedia application environment



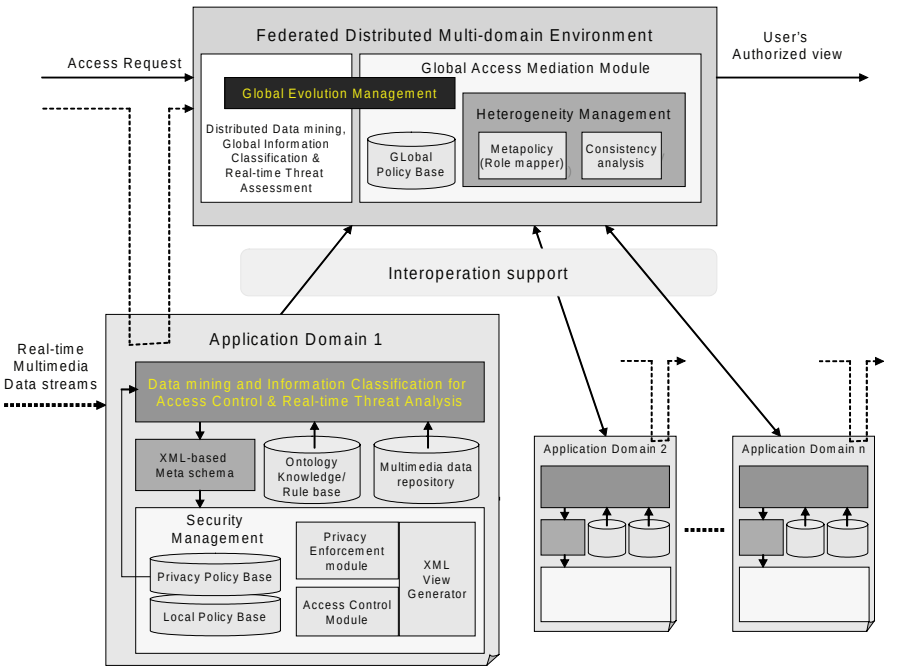
schema, by integrating multimedia presentation information with security and privacy attributes. The *knowledge/rule base* or the *ontology* will be used by the information classification and security cluster generator module.

The *Multi-level Content Analysis, Data Filtering and Pre-processing Module* (MCADFPM) is responsible for (1) conducting multi-level content analysis for mining and learning the semantic information; (2) exploiting suitable multi-resolution representation schemes for various media features, segments, and objects; and (3) enabling automatic feature selection to reach the compact sets of features and dataset for data mining in the data-filtering and preprocessing step. The module assists in generating the security clusters and their attribute and feature sets. The *Distributed Data Mining and Real-time Threat Analysis Module* (DDMRTAM) is responsible for designing and developing (1) distributed data mining techniques for threat assessment based on real-time streams and (2) an information fusion model to resolve the inconsistencies when integrating the classification results from multiple local classifiers. The information clusters that it generates are organized in a hierarchy and represented in an XML.

Conceptual System Architecture for a Multi-Domain Multimedia System

Figure 2 depicts the key components of the conceptual architecture of a secure federated distributed, multi-domain multimedia environment. The *Distributed Data Mining, Global Information Classification and Threat Assessment* component maintains global level views of conceptual objects based on the security clusters of individual domains. It also allows inter-site conceptual mapping of information objects and distributes real-time threat assessment tasks with the help of the ontology or knowledge base of each domain. The *Global Access Mediation Module* integrates all the local policies into a unified *Global Policy Base*. The *Heterogeneity Management* module resolves any semantic differences and incon-

Figure 2. Conceptual design of a multi-domain multimedia application environment



sistencies among the local policies when the global policy is constructed using the *Consistency Analysis* module. The final global level policy generated for the whole multi-domain environment primarily consists of a *Role Mapper* that maintains the mapping from global roles to local roles for access mediation. For a global access request, these mappings are used to issue access requests to individual domains. *Global Evolution Management* module is responsible for overseeing the process of ensuring consistent evolution of local information classification mechanisms and security/privacy policies.

SCALABLE MULTIMEDIA DATA ANALYSIS AND MINING TECHNIQUES

Content-based analysis of multimedia information for facilitating distributed security policies is a challenging issue because of the multi-modality nature of multimedia data and heterogeneity of distributed information sources and sensors. Scalable real-time content-based analysis and mining frameworks are needed to generate security-oriented classification of multimedia information for the distributed multi-domain environment and to provide capabilities for real-time threat assessment. An efficient approach of real-time data stream querying across multiple domains needs to be developed. A set of classifiers, both for individual domains and for global environment, that use a set of training data over relatively long timeframes is essential. Based on the semantics and the contents of information, these classifiers will produce a set of security clusters of multimedia objects, each with a set of features and attributes that can be used for developing information security and privacy policies for single and multi-domain environments, as discussed later. Another key challenge for designing the global classifier for multiple domains is to fuse information from local classifiers and resolve any semantic conflicts and inconsistencies

in an efficient manner. Figure 3 depicts the data analysis and classification processes involved in multimedia information systems.

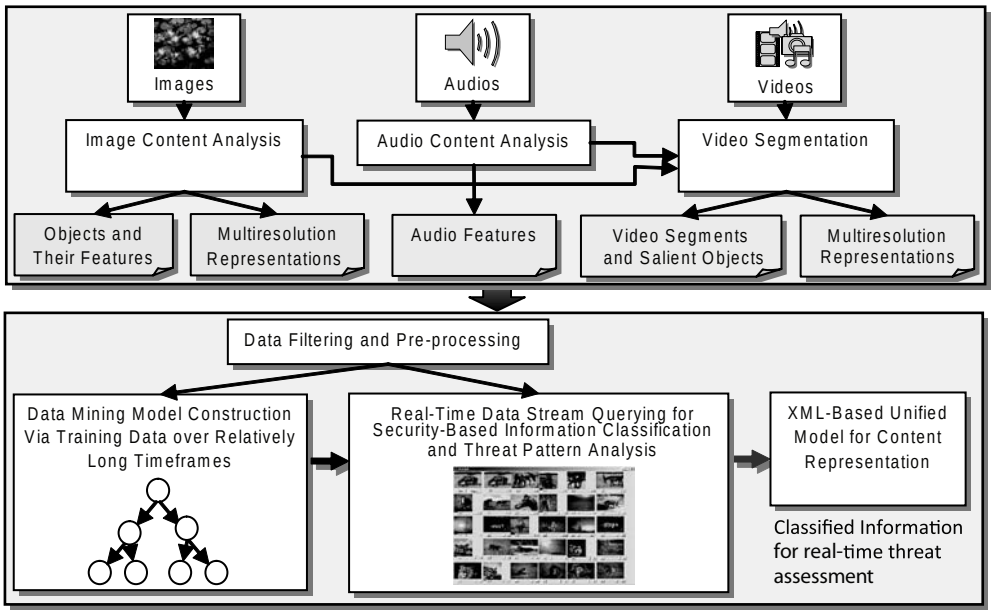
Real-Time Content Analysis of Multi-Modality Multimedia Data. An in-depth content analysis and mining of multimedia data can provide a tremendous wealth of information useful for security management and threat assessment. For this purpose, multi-modality content analysis is essential for integrating and transforming multimedia data into a format suitable for off-line data mining model construction and development of security clusters. Such analysis can span relatively long timeframes. On the other hand, data stream querying for classification and threat assessment requires real-time processing.

Multi-Level Content Analysis of Multi-Modality Data. To automate multi-level real-time content analysis of multimedia data, a framework is needed that allows:

1. extraction of low-level features, including the color and shape features of an image or video frame and the energy feature of an audio segment;
2. extraction of mid-level features such as the object segmentation based on statistical features of the low-level features and the video shot/scene segmentation;
3. extraction of high-level features that identify high-level multimedia content or events; and
4. incremental learning to adapt to the changes in semantics over time.

Mining single-modality alone is not enough to reveal and interpolate the complex correlations of multiple data modalities from diverse sources. Therefore, it is more desirable to discover knowledge from multimedia data with multi-modalities and temporal relationships (Chen et al., 2003; Chen et al., 2004; Dagtas & Abdel-Mottaleb, 2001). A conceptually simple problem in infor-

Figure 3. Architecture of multi-modal content data analysis and real-time data mining



mation fusion is the combination of *opinions* of multiple classifiers. Several information fusion frameworks have been proposed, including the *Bayesian model*, *majority voting rule*, *average of classifier outputs*, *Naïve-Bayes*, *decision template*, and *dynamic classifier selection* (DCS) for integrating information from sources with different modalities (Giacinto, Roli, & Didaci, 2003; Krzysztofowicz & Long, 1990).

Representation of Multimedia Data. Conventional multimedia database systems represent multimedia objects at the single level resolution. Multi-resolution representation consists of maintaining multiple and concurrent representation of multimedia objects and plays an important role in providing semantics to support access control and privacy of information. For example, a confidential medical X-ray image may also have the patient identity information. However, only the version without the identity information should be displayed to unauthorized users. Multi-resolution representation schemes for static images and video data based on the multi-splines method have been proposed in Moni and Kashyap (1995), which has shown to yield excellent visual image quality. In addition, multi-resolution representation provides an attractive solution in terms of coding complexity and image quality.

Real-Time Security-Based Information Classification and Threat Assessment. A set of suitable data mining classifiers, both for individual domains and for the distributed multi-domain environment, are required to support a comprehensive security framework. Such classifiers can be constructed off-line using the training data over relatively long timeframes and used to generate information categorization for implementing the underlying content-based access control policies with a wide range of classification parameters such as sensitivity level of information, its importance, and its semantics. In addition, real-time classifiers are needed to perform threat pattern analysis for detecting any emerging threats. The global classifier will integrate all the local classifiers and resolve the inconsistencies of the information among the local classifiers. These classifiers can generate security clusters consistent with access control and privacy management policies. Steps involved in the information classification process are discussed next.

Data Filtering and Pre-processing. The most challenging step prior to carrying data mining is to clean and prepare the data via data cleaning tools and/or domain-specific security knowledge or rules to ensure that the inputs of the data mining models are consistent with the overall security goals. The lack of a guide to choose the most appropriate subfeature set can severely limit the effectiveness and efficiency of data pre-processing. Moreover, in cases when security knowledge is not available, selecting a subset of compact features can become a bottleneck, especially when the features set is large. Several research works address this issue (Chen et al., 2003; Dy & Brodley, 2000; Shyu et al., 2003). A challenge is to develop efficient data cleaning and prefiltering techniques by enabling automatic security and privacy policy driven feature selection and eliminating unnecessary data records with the aid of domain knowledge.

Real-time Content Correlation of Multiple Streams for Event Detection. There exist no scalable mechanisms that can automatically correlate and synchronize multiple streams in multimodalities and in spatial/temporal dimensions to support real-time data stream querying and event detection. Recently, a technique based on event-template for mining event information by combining audio and video cues to discover high level events in a medical database, such as surgery and patient-physician dialogs in the context of a video database management system was proposed (Aref et al., 2003; Hammad, Franklin, Aref, &

Elmagarmid, 2003; Sandhu, Coyne, Feinstein, & Youman, 1996; Zhu et al., 2003).

Off-line Data Mining Model Construction. Given the training data generated from the data filtering and pre-processing steps, another challenge is to develop a suitable, scalable data mining classifier that can generate relevant security clusters and their feature and attribute sets for implementing access control policies and identifying threat patterns. A data mining classifier is constructed off-line by using the training data over relatively long timeframes. Generally, such classifiers can be used not only in evolving the existing threat patterns but also in discovering new threat patterns, which is extremely vital in real-time threat assessment. Conflicts and inconsistencies may arise while integrating information from multiple classifiers belonging to different domains into a global classifier, requiring information fusion to resolve these problems. A number of fusion rules can be used to combine an individual classification generated by training local classifiers.

XML-based Unified Model for Content Representation. The security clusters identified by the data mining step will consist of complex multimedia objects, which usually come from multiple application domains and in multi-modalities; hence, a unified model for content representation is needed. One promising approach is to use XML for multimedia content representation and develop an XML-based meta-schema for the security clusters and their attribute and feature sets so that these clusters and their sets can be directly used for developing the security management component. In addition, the XML-based meta-schema will represent the multimedia composition schema for secure presentation instances that may be composed of text, audio, video, and images. XML-based meta-schema is also used to represent the information retrieved by the data mining process and to identify multimedia documents and objects corresponding to the features and classes that the classifiers use, forming a high level conceptual "document."

DISTRIBUTED MULTIMEDIA SECURITY AND PRIVACY MANAGEMENT

The development of a fine-grained, content and context based access control and privacy model for multimedia applications raises a number of serious technical challenges. The privacy issue is a major concern in multimedia systems. Efficient techniques are required to generate correct mapping between the security and privacy requirements and the data analysis and classification mechanisms that generate security clusters. A unified XML-based language for expressing the security and privacy policies, as well as complex synchronization constraints, can provide a basis for wider acceptance for practical use.

Access Control and Privacy Protection for Multimedia Information Systems

Access control may need to be applied at different levels of granularity and over hierarchically arranged multimedia objects. Few existing access control models address specific requirements of multimedia information systems. Bertino, Hammad, Aref, and Elmagarmid (2000) proposed a video database access control model that allows access control at various levels of granularity of video information, including video frames, video objects, or a sequence. Joshi, Fahmi, Shafiq, and Ghafoor (2002) proposed a *Secure Generalized Object Composition Petri-net* (Secure-GOCPN) model by extending the GOCPN model of multimedia documents to support multi-level security policies by classifying multimedia information into a prespecified set of classification levels.

Subjects are also assigned security clearances that allow them to view information at or below a particular classification level. The unclassified level may correspond to preventing certain frames from being viewed by an unclassified user or hiding sensitive information from each frame. Using the mapping of classification levels across multiple domains, an implementation architecture that supports the presentation of distributed multimedia documents that include media documents/objects from multiple sources was presented in Joshi et al. (2002). The Secure-GOCPN model, however, only supports multi-level security policy. We propose using a role-based access control (RBAC) approach to address the generic security and privacy requirements of multimedia applications. RBAC supports fine-grained separation of duty (SoD) constraints, principle of least privilege, and efficient permission management. It also facilitates easy integration of policies because of the similarity of roles in different application domains (Ahn & Sandhu, 2000; Ferraiolo et al., 2001; Joshi et al., 2001; Kobsa & Schrek, 2003; Sandhu, Ferraiolo, & Kuhn, 2000). Atluri, Adam, Gomaa, and Adiwijaya (2003) proposed a preliminary formal model of access control of multimedia information by enhancing Synchronized Multimedia Integration Language (SMIL) to express policies.

A Parameterized RBAC Approach to Multimedia Information Systems. In an open environment such as the Web, a system should be able to facilitate a dynamic association of unknown users to a set of authorized actions. A content-based, context-aware RBAC framework would allow the users to be mapped to the activities authorized for them, based on context and credential information they present when requesting accesses. Roles also provide an abstraction level that can be used to capture security relevant features of multimedia objects and the security clusters generated by data mining tools. To handle these issues, one approach is to use parameterized roles and role preconditions that will test the attribute and feature sets of the security clusters and multimedia objects being accessed, the credentials of the requester, and the contextual information that should be valid at the time of access. Along this direction, significant work has been done in the temporal RBAC (TRBAC) model by Bertino, Bonatti, and Ferrari (2001) and later in the generalized TRBAC (GTRBAC) model by Joshi, Bertino, Latif, and Ghafoor (2005). Depending on the application semantics, not all roles may be available to all users at any time. This notion is reflected in the GTRBAC model by defining the following states of a role: *disabled*, *enabled*, and *active*. The *disabled* state indicates the role cannot be activated in a session. The *enabled* state indicates that authorized users activate the role. A role in the *active* state implies that there is at least one user who has activated the role. Accordingly, the preconditions that change the states of a role are: (1) *role enabling/disabling precondition* to enable/disable a role; (2) *role assignment/deassignment precondition* to assign/deassign a user (or permission) to the role; and (3) *role activation/deactivation precondition* that specifies an authorized user can activate a role or when a role should be deactivated.

Though several researchers have addressed access control using parameterized roles, no formal model has been presented by any. One approach is to extend the event-based GTRBAC model to develop a comprehensive event and rule-based, parameterized RBAC framework. A preliminary version of a parameterized role is presented in Joshi, Bhatti, Bertino, and Ghafoor (2004), which essentially builds on the event-based constraint framework of the GTRBAC model.

Extension of an XML Language for CC-RBAC Policies. We propose using an XML language that can express CC-RBAC modeling entities such as user credentials, role events and preconditions, clusters and multimedia objects, and permissions associated with them by adopt-

ing the X-RBAC language proposed by Joshi et al. (2004). A general credential expression of the form (*credTypeID, attributes*), where *credTypeID* is a credential type identifier and *attributes* is a set of attribute-value pairs, is used to map unknown users to predefined roles. In Joshi et al. (2004), an XML language for the basic RBAC model has been proposed to support parameterized RBAC policies. X-RBAC has been developed specifically for protecting XML content—*schema*, *instances*, and *elements*. The *schema*, *instances*, and *elements* of XML documents can naturally be extended to address the requirements of multimedia documents. Based on access control defined for the security clusters of multimedia objects and the presentation schema for such objects, presentation views for the users can be generated. Conceptual level access control policies use concept roles (Bhatti, Joshi, Bertino, & Ghafoor, 2003). It is possible that a schema element does not belong to the cluster to which its parent element belongs. It may further be necessary to specify that the element is not protected by a schema-level policy. At the lowest granularity, the protection may be applied to the fragments of an object such as on portions of a video sequence and individual frames. The XML document structure for the specification of multimedia information also demands a specific set of privileges such as authoring a part of the XML document, modifying attributes only of a particular subset of the XML specification of a multimedia presentation, and navigating privileges to allow the use of links to navigate linked multimedia information.

A considerable amount of work on RBAC can be found in the literature (Ahn & Sandhu, 2000; Ferraiolo et al., 2001; Sandhu et al., 2000). Giuri and Iglio (1997) presented the concepts of parameterized privileges and role templates to allow the specification of policies based on the content of the objects. In Georgiadis, Mavridis, Pangalos, and Thomas (2001), the context of a team is composed of user context and object context. None of these studies addresses the consistency issues and complex requirements of multimedia applications. The environment roles in Covington et al. (2001) are essentially statically defined context roles and thus cannot be employed in a dynamic environment. In Adam, Atluri, and Bertino (2002), a content-based access control (CBAC) model for a digital library has been proposed to protect the textual content of digital archives, uses credentials, and concept hierarchies. Related work also includes several security mechanisms for schema and XML-instance level protection of XML documents (Bertino et al., 1999; Damiani et al., 2002). Qin and Atluri (2003) recently proposed a content-based access control model for Semantic Web and used the concept level protection. These studies, however, do not address the security challenges in emerging multimedia applications mentioned earlier using an RBAC approach.

Privacy Protection in Multimedia Information Systems. In multimedia information systems, privacy concerns exist at multiple layers (Adams & Sasse, 1999). At a primary level, privacy relates to the sensitivity of actual information content of the multi-modal data. At the secondary level, it relates more to the sociopsychological characteristics of the data being accessed (Adams & Sasse, 1999). For example, the clips about medical procedures may be used for teaching purposes, but if the clip shows a patient and his/her employer views it, it may have a detrimental effect, in particular, if the patient has a serious mental disease. While such multimedia clips may be of significant research value, appropriate measures need to be taken to ensure that privacy is protected. The three key factors of privacy protection are: *information sensitivity*, *information receiver*, and *information use* (Adams & Sasse, 1999; Jiang & Landay, 2002). Privacy policies indicate who receives what level of private information for what use. A relevant issue is the inference problem (Thuraisingham, 2003). For instance, disease information may be inferred by collecting information on prescrip-

tion data related to a patient. In particular, data mining can be used to infer facts that are not obvious to human analysis of data. In such cases, we need to protect private information that may be inferred.

A model for user privacy: In general, an application domain provides a privacy policy to protect users' private information that may have been maintained as historical profiles or credential data collected for authorization purposes (Ashley, Hada, Karjoth, & Schunter, 2002; Jiang 2002; Tavani 2001). User consent is needed for releasing such private information to other parties. In particular, privacy requirements may need to be expressed as content-based and association-based constraints (Thuraisingham, 2003). A key challenge is thus to develop a privacy model and an enforcement mechanism that will be driven by the domain rules and user-controlled privacy policies. Suitability of several existing approaches to privacy management has not been applied to multimedia environments. The *sticky policy* based approach proposed in Ashley, Hada, Karjoth, and Schunter (2002) uses privacy statements that *stick* to each piece of private information so that the privacy statements can be checked before the information is accessed. Another relevant approach uses privacy tags and defines an information space boundary (*physical*, *social*, or *activity-based*) as a contextual trigger to enforce permissions defined by the owners of that space (Jiang & Landay, 2002). To address flexible privacy requirements in multimedia applications, these approaches may need to be combined, and the use of parameterized roles can provide significant benefits (Kobsa & Schrek, 2003). One key issue is when a user specifies a privacy policy, the document itself becomes a protected object and may conflict with the overall privacy policy of the domain.

Privacy-aware information classification: To provide a fine-grained control over the release of private information, a mechanism is needed to provide the interaction between the data mining component that generates security clusters and the privacy protection module. Assume that a personal privacy policy states that "*None other than the concerned doctors should view any information that may reveal my disease*". Here, "*any information that may reveal my disease*" may simply be text containing a prescription drug name, the disease name, or a video sequence showing the patient's physical features and indicating signs of the disease; and the "*concerned doctors*" is an abstract concept referring to a user group with certain characteristics. Meta-information from the privacy-policy base can be used as the domain knowledge for supporting the information classifiers at the time of generating security classes and their attributes and feature sets. Furthermore, data mining can reveal new sensitive and private information and associations that may not be possible through human analysis. For such information, if privacy statements do not exist, new privacy policies may need to be generated. Hence, the development of mechanisms that allow efficient interactions between the privacy protection and data mining modules is needed to iteratively refine both privacy policies and information classification. The overall privacy protection component in the proposed research is depicted in Figure 4. The access control module interacts with the privacy mechanism to ensure that privacy requirements are met before users can access data. Several privacy protection models and approaches have been discussed (Adams & Sasse, 1999; Ashley, Hada, Karjoth, & Schunter, 2002; Ashley, Powers, & Schunter, 2002; Jiang & Landay, 2002; Kobsa & Schrek, 2003; Mont, Pearson, & Bramhall, 2003; Tavani & Moor, 2001).

Management of Secure Multi-Domain Multimedia Information Systems

Heterogeneity is a uniquely complex challenge, as security and privacy policies and information classification methodologies may vary over all the

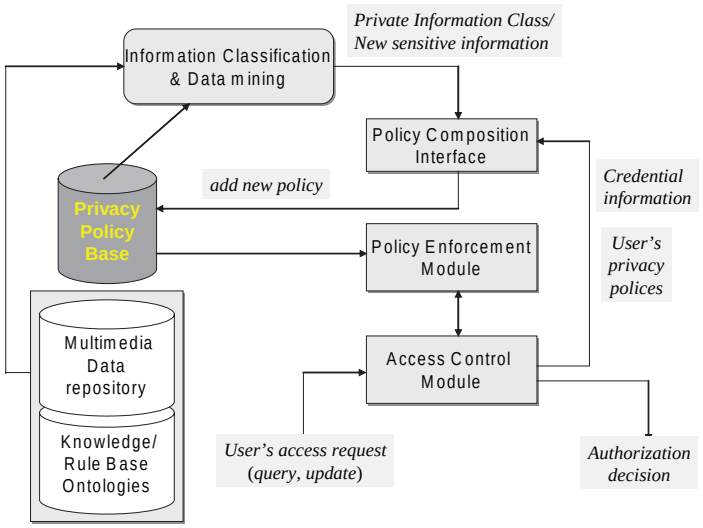
domains giving rise to inconsistent inter-domain actions. The key challenges for developing secure distributed, multi-domain multimedia information systems are (1) to identify conflicts among security and privacy policies and (2) to maintain a consistent global information classification.

The overall infrastructure for a secure distributed multi-domain multimedia application environment must allow seamless and secure interoperation among the diverse access control policies employed by each domain. Such an infrastructure should be scalable, open, and extensible (Joshi et al., 2001) and should allow any domain with an arbitrary security policy and information classification to be a part of the overall environment. An XML-based policy specification and enforcement framework can provide a more practical solution for secure interoperation in multi-domain multimedia environments.

In a multi-domain environment, individual domain policies may follow different conventions and use varying attributes. Semantic heterogeneity may give rise to naming or structural conflicts, a problem that is commonly encountered during schema integration in a heterogeneous federated database system (Batini, Lenzerini, & Navathe, 1986). Naming conflicts occur due to the use of a single name to refer to different concepts. Known techniques from the integration of heterogeneous databases and ontology can be utilized to resolve naming conflicts (Batini et al., 1986). Conflicts can also arise because of the differences in the representation of similar constraints. In the CC-RBAC framework, the constraints can make the semantic heterogeneity issue even more difficult to address. It makes evolution management a significant problem.

Different application domains may use different data analysis and classification mechanisms to generate an equivalent set of concepts with different names or different concepts with similar names. At the global level, such semantic differences need to be properly resolved to ensure secure information access and privacy protection. In each application domain, there is an interaction between the information classification and policy generation modules as indicated in Figure 5. Once policies and information classification consistent to each other have been generated, the global level policy is generated. At the same time, a consistent global level classification also needs to be generated from local classifications. The global

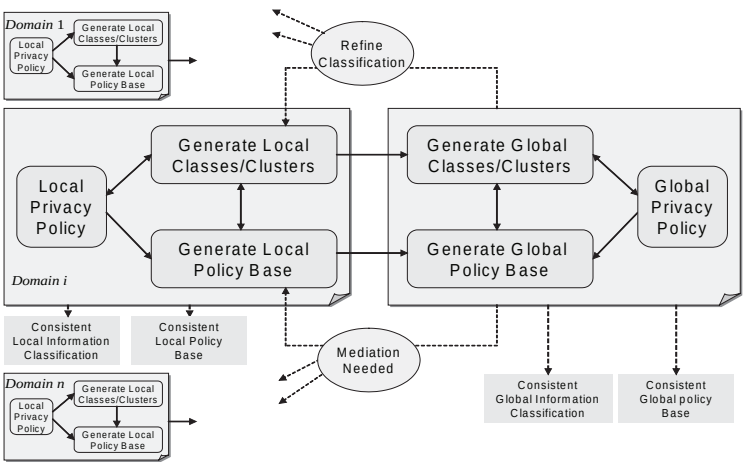
Figure 4. Privacy protection component



level policy and global level classification may be inconsistent if the local domains employ different classification schemes. To resolve such inconsistencies, local classifiers may need to be refined, which in turn affects the local policies. Hence, the global level policy generated earlier will now become inconsistent requiring further mediation of local policies. Such multi-dimensional horizontal and vertical interactions among the classification and policy generation modules at the two levels make the overall integration problem significantly complex. The challenge is to develop a framework for iteratively refining policies and information classes at the two levels. Local clusters/classes are extracted by data mining tools and are used as protection objects. Refinement of classifiers and mediation policies needs to be iterated until consistent classifications and policies are generated at each local domain as well as at the global level. The presence of dynamic and contextual roles can make the problem even more complex. Techniques are needed for detecting inconsistencies, automatically or semi-automatically, using attribute-based matching and ontologies. In particular, use of ontology to assist in semantic mapping between security policies of different domains is becoming a possibility because of tools such as RDF, DAML+OIL, and/or OWL. An ontology can be defined as "the specification of conceptualizations, used to help programs and humans share knowledge" (Hunter, 2003). Use of ontologies in the integration of security policies needs to be similarly explored. In particular, for securing a distributed multi-domain application, use of ontologies related to the domain knowledge as well as the security policies and mechanisms of the individual administrative domains will be crucial to capture the names used to indicate various security attributes and their intended semantics and relationships.

Limited work has been done in the area of secure interoperation in a multi-domain environment. In Shafiq, Joshi, Bertino, and Ghafoor (2004), a policy composition framework for integrating simple RBAC policies to provide secure interoperation has been proposed, where RBAC constraints are transformed into an integer programming problem to optimize secure interoperation. In Joshi et al. (2004), the XML-based RBAC framework has been extended to specify arbitrary multi-domain policies. Integration of multiple policies has been focused generally on MAC mechanisms for federated database systems. Thuraisingham and Ford (1995) discussed methodologies for constraint processing in a multi-level, secure, centralized, and distributed

Figure 5.The integration process



database management system. In Jonscher and Dittrich (1995), the global access layer is used to map global authorizations into local access rights for the individual systems. XML-based tools to manage RBAC policies in an enterprise have been discussed in Vuong, Smith, and Deng (2001).

CONCLUSIONS

In this chapter, we have presented a conceptual architectural framework for open, distributed multimedia information systems that aims at ensuring security and privacy of multimedia information and provides a mechanism for threat assessment. The proposed framework uses XML technologies to address the needs for multi-resolution representation of multi-modal multimedia data, its storage, exchange, and retrieval, as well as to develop access control and privacy specifications. We have discussed the relevance of a content and context based RBAC approach to capture both the access control and privacy requirements of multimedia applications. The framework addresses the need for a holistic solution to supporting flexible access control and privacy requirements on multimedia information. Such information may contain sensitive and private data and can be analyzed to reveal patterns and knowledge for possible threats to an enterprise. The framework provides security and privacy protection while facilitating real-time and long-term analysis to detect potential threats.

ABSTRACT

Most of the video retrieval systems work with a single shot without considering the temporal context in which the shot appears. However, the meaning of a shot depends on the context in which it is situated and a change in the order of the shots within a scene changes the meaning of the shot. Recently, it has been shown that to find higher-level interpretations of a collection of shots (i.e., a sequence), intershot analysis is at least as important as intrashot analysis. Several such interpretations would be impossible without a context. Contextual characterization of video data involves extracting patterns in the temporal behavior of features of video and mapping these patterns to a high-level interpretation. A Dynamic Bayesian Network (DBN) framework is designed with the temporal context of a segment of a video considered at different granularity depending on the desired application. The novel applications of the system include classifying a group of shots called sequence and parsing a video program into individual segments by building a model of the video program.

INTRODUCTION

Many pattern recognition problems cannot be handled satisfactorily in the absence of contex-

tual information, as the observed values underconstrain the recognition problem leading to ambiguous interpretations. Context is hereby loosely defined as the local domain from which observations are taken, and it often includes spatially or temporally related measurements (Yu & Fu, 1983; Olson & Chun, 2001), though our focus would be on the temporal aspect, that is, measurements and formation of relationships over larger timelines. Note that our definition does not address a contextual meaning arising from culturally determined connotations, such as a rose as a symbol of love.

A landmark in the understanding of film perception was the Kuleshov experiments (Kuleshov, 1974). He showed that the juxtaposition of two unrelated images would force the viewer to find a connection between the two, and the meaning of a shot depends on the context in which it is situated. Experiments concerning contextual details performed by Frith and Robson (1975) showed a film sequence has a structure that can be described through selection rules.

In video data, each shot contains only a small amount of semantic information. A shot is similar to a sentence in a piece of text; it consists of some semantic meaning which may not be comprehensible in the absence of sufficient context. Actions have to be developed sequentially; simultaneous or parallel processes are shown one after the other in a concatenation of shots. Specific domains contain rich temporal transitional structures that help in the classification process. In sports, the events that unfold are governed by the rules of the sport and therefore contain a recurring temporal structure. The rules of production of videos for such applications have also been standardized. For example, in baseball videos, there are only a few recurrent views, such as pitching, close up, home plate, crowd and so forth (Chang & Sundaram, 2000). Similarly, for medical videos, there is a fixed clinical procedure for capturing different video views and thus the temporal structures are exhibited.

The sequential order of events creates a temporal context or structure. Temporal context helps create expectancies about what may come next, and when it will happen. In other words, temporal context may direct attention to important events as they unfold over time.

With the assumption that there is inherent structure in most video classes, especially in a temporal domain, we can design a suitable framework for automatic recognition of video classes. Typically in a Content Based Retrieval (CBR) system, there are several elements which determine the nature of the content and its meaning. The problem can thus be stated as extracting patterns in *the temporal behavior of each variable and also in the dynamics of relationship between the variables, and mapping these patterns to a high-level interpretation*. We tackle the problem in a Dynamic Bayesian Framework that can learn the temporal structure through the fusion of all the features (for tutorial, please refer to Ghahramani (1997)).

The chapter is organized as follows. A brief review of related work is presented first. Next we describe the descriptors that we used in this work to characterize the video. The algorithms for contextual information extraction are then presented along with a strategy for building larger video models. Then we present the overview of the DBN framework and structure of DBN. A discussion on what needs to be learned, and the problems in using a conventional DBN learning approach are also presented in this section. Experiments and results are then presented, followed by discussion and conclusions.

RELATED WORK

Extracting information from the spatial context has found its use in many applications, primarily in remote sensing (Jeon & Landgrebe, 1990; Kittler & Foglein, 1984), character recognition (Kittler & Foglein, n.d.), and detection of faults and cracks

(Bryson et al., 1994). Extracting temporal information is, however, a more complicated task but it has been shown to be important in many applications like discrete monitoring (Nicholson, 1994) and plan recognition tasks, such as tracking football players in a video (Intille & Bobick, 1995) and traffic monitoring (Pynadath & Wellman, 1995). Contextual information extraction has also been studied for problems such as activity recognition using graphical models (Hamid & Huang, 2003), visual intrusion detection (Kettnaker, 2003) and face recognition.

In an interesting analysis done by Nack and Parkes (1997), it is shown how the editing process can be used to automatically generate short sequences of video that realize a particular theme, say humor. Thus for extraction of indices like humor, climax and so forth, context information is very important. A use of context for finding an important shot in a sequence is highlighted by the work of Aigrain and Joly (1996). They detect editing rhythm changes through the second-order regressive modeling of shot duration. The duration of a shot PRED (n) is predicted by (1) where the coefficients of a and b are estimated in a 10-shot sliding window. The rule employed therein is that if (Tn > 2 *PRED (n)) or (Tn < PRED (n)/2) then it is likely that the nth shot is an important (distinguished) shot in a sequence. The above model was solely based on tapping the rhythm information through shot durations. Dorai and Venkatesh (2001) have recently proposed an algorithmic framework called computational media aesthetics for understanding of the dynamic structure of the narrative structure via analysis of the integration and sequencing of audio/video elements. They consider expressive elements such as tempo, rhythm and tone. Tempo or pace is the rate of performance or delivery and it is a reflection of the speed and time of the underlying events being portrayed and affects the overall sense of time of a movie. They define P (n), a continuous valued pace function, a

$$P(n) = W(s(n)) + \frac{m(n) - \mu_m}{\sigma_m}$$

where s refers to shot length in frames, m to motion magnitude, μ_m and σ_m, to the mean and standard deviation of motion respectively and n to shot number. W (s(n)) is an overall two-part shot length normalizing scheme, having the property of being more sensitive near the median shot length, but slows in gradient as shot length increases into the "longer" range.

We would like to view the contextual information extraction from a more generic perspective and consider the extraction of temporal pattern in the behavior of the variables.

THE DESCRIPTORS

The perceptual level features considered in this work are Time-to-Collision (TTC), shot editing, and temporal motion activity. Since our emphasis is on presenting algorithms for contextual information, they are only briefly discussed here. The interested reader can refer to Mittal and Cheong (2001) and Mittal and Altman (2003) for more details. TTC is the time needed for the observer to reach the object, if the instantaneous relative velocity along the optical axis is kept unchanged (Meyer, 1994). There exists a specific mechanism in the human visual system, designed to cause one to blink or to avoid a looming object approaching too quickly. Video shot with a small TTC evokes fear because it indicates a scene of impending collision. Thus, TTC can serve as a potent cue for the characterization of an accident or violence.

Although complex editing cues are employed by the cameramen for making a coherent sequence, the two most significant ones are the shot transitions and shot pacing. The use of a particular shot transition, like dissolve, wipe, fade-in, and so forth, can be associated with the possible intentions of the movie producer. For example,

dissolves have been typically used to bring about smoothness in the passage of time or place. A shot depicting a close-up of a young woman followed by a dissolve to a shot containing an old woman suggests that the young woman has become old. Similarly, shot pacing can be adjusted accordingly for creating the desired effects, like building up of the tension by using a fast cutting-rate. The third feature, that is, temporal motion feature, characterizes motion via several measures such as total motion activity, distribution of motion, local-motion/global-motion, and so forth.

Figure 1 shows the effectiveness of TTC in the content characterization with the example of a climax. Before the climax of a movie, there are generally some chase scenes leading to the meeting of bad protagonists of a movie with good ones. One example of such a movie is depicted in this figure, where the camera is shown both from the perspective of the prey and of the predator leading to several large lengths of the impending collisions as depicted in Figure 2. During the climax, there is a direct contact, and therefore collision length is small and frequent. Combined with large motion and small shot length (both relative to the context), TTC could be used to extract the climax sequences.

Many works in the past have focused on shot classification based on single-shot features like color, intensity variation, and so forth. We believe that since each video class represents structured events unfolding in time, the appropriate class signatures are also present in the temporal domain. The features such as shot-length, motion, TTC, and so forth, were chosen to illustrate the importance of temporal information, as they are perceptual in nature, as opposed to low-level features such as color, and so forth.

CONTEXT INFORMATION EXTRACTION

Hierarchy of Context

Depending on the level of abstraction of the descriptors, the context information can be coarsely

Figure 1. Shots leading to climax in a movie

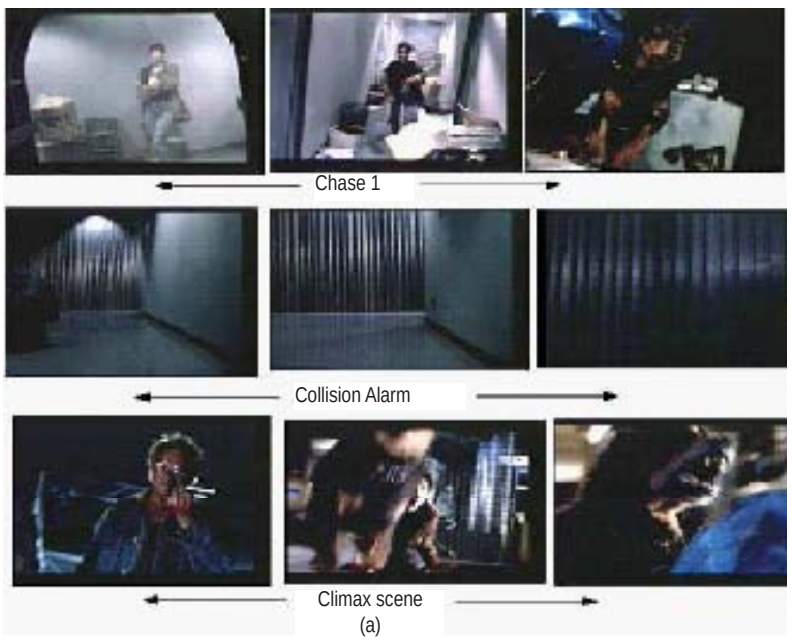

Figure 2. Feature values for the shots in Figure 1. Shots in which TTC length is not shown correspond to a case when TTC is infinite; that is, there is no possibility of collision.

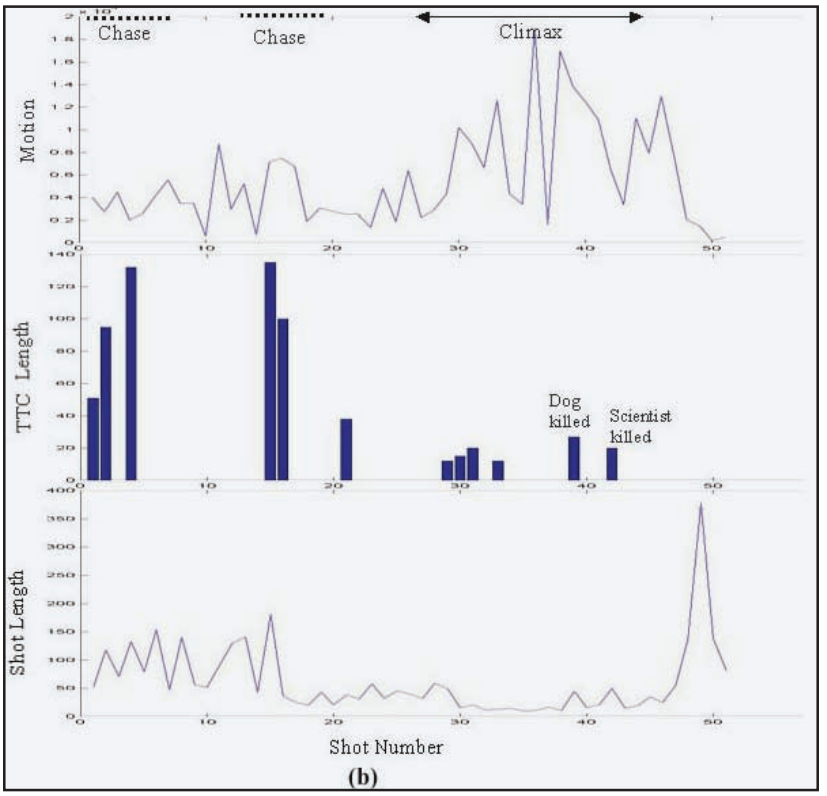


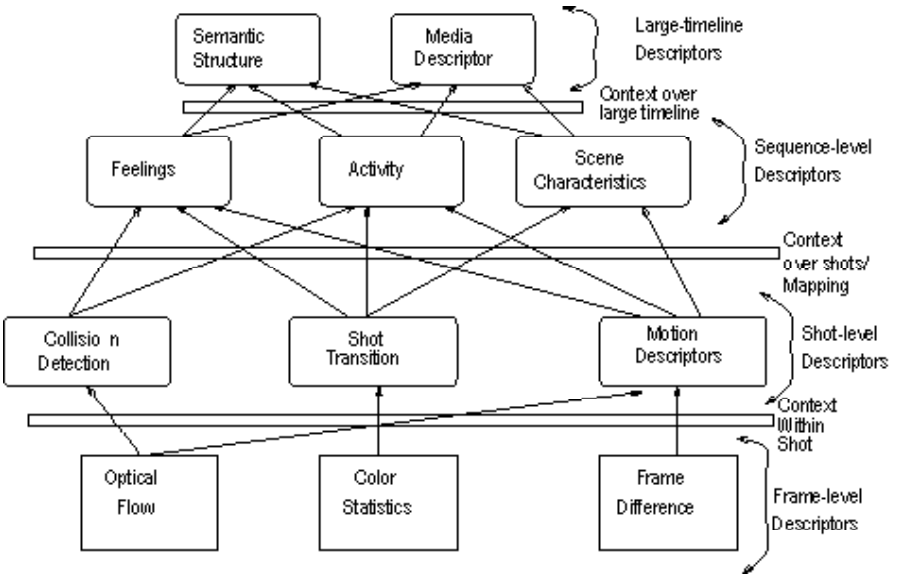
(i.e., large neighborhood) or finely integrated. Figure 3 shows a hierarchy of descriptors in a bottom-up fashion where each representational level derives its properties from the lower levels. At the lowest level of the hierarchy are properties like color, optical flow, and so forth, which correspond only to the individual frames. They might employ the spatial context methods that are found in the image processing literature.

At the second lowest level are descriptors such as TTC, shot transition details, and so forth, which derive their characteristics from a number of frames. For example, patterns in the mean and variance of color features computed over a number of frames (i.e., context) are used in identifying shot-transition (Yeo & Liu, 1995). Similarly, the context over frames is used for collision detection by identifying a monotonically decreasing TTC, and for the extraction of motion descriptors (like local-motion/global-motion).

At the next higher level are the sequence level descriptors (or indices), which might require the information of several shots. Some examples of these descriptors could be in terms of feelings (like interesting, horror, excitement, sad, etc.), activity (like accident, chase, etc.) and scene characteristics (like climax, violence, newscaster, commercial, etc.). For example, a large number of collisions typically depict a violent scene, whereas one or two collision shots followed by a fading to a long shot typically depicts a melancholy scene. If the context information over the neighboring shots is not considered, then these and many other distinctions would not be possible.

Finally, these indices are integrated over a large timeline to obtain semantic structures (like

Figure 3. A hierarchy of descriptors



for news and sports) or media descriptors. An action movie has many scenes where violence is shown, a thriller has many climax scenes and an emotional movie has many sentimental scenes (with close-ups, special effects, etc.). These make it possible to perform automatic labeling as well as efficient screening of the media (for example, for violence or for profanity).

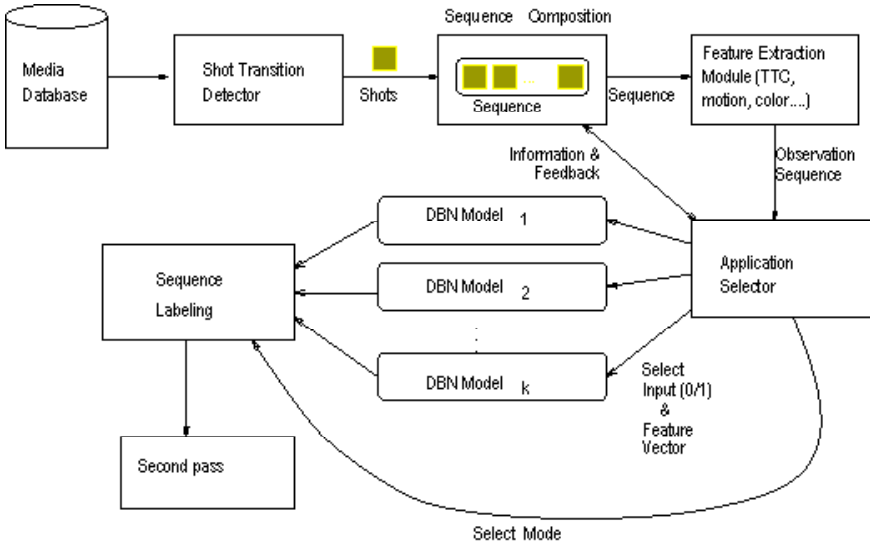
Descriptors at different levels of the hierarchy need to be handled with different strategies. One basic framework is presented in the following sections.

The Algorithm

Figure 4 depicts the steps in a context information extraction (mainly the first pass over the shots). The digitized media is kept in the database and the shot transition module segments the raw video into shots. The sequence composer groups a number of shots (say /) based on the similarity values of the shots (Jain, Vailaya, & Wei, 1999) depending on the selected application. For example, for applications like climax detection, the sequences consist of a much larger number of shots than that for the sports identifier.

The feature extraction of a sequence yields an observation sequence, which consists of feature vectors corresponding to each shot in the sequence. An appropriate DBN Model is selected based on the application, which determines the complexity of the mapping required. Thus, each application has its own model (although the DBN could be made in such a way that a few applications could share a common model, but the performance would not be optimal). During the training phase, only the sequences corresponding to positive examples of the domain are used for learning. During the querying or labeling phase, DBN evaluates the likelihood of the input observation sequence belonging to the domain it represents. The sequence labeling module and the application selector communicate with each other to define the task which needs to be performed, with the output being a set of likelihoods. If the application involves classifying into one of the exclusive genres, the label corresponding to the DBN model with the maximum likelihood is as-

Figure 4. Steps in context information extraction (details of the first pass are shown here)



signed. In general, however, a threshold is chosen (automatically during the training phase) over the likelihoods of a DBN model. If the likelihood is more than the threshold for a DBN model, the corresponding label is assigned. Thus, a sequence can have zero label or multiple labels (such as "interesting", "soccer", and "violent") after the first pass. Domain rules aid further classification in the subsequent passes, the details of which are presented in the next section.

Context Over Sequences: The Subsequent Passes

The algorithm in the subsequent passes is dependent on the application (or the goal). The fundamental philosophy, however, is to map the sequences with their labels onto a one-dimensional domain, and apply the algorithms relevant in the spatial context. A similar example could be found in the character recognition task, where the classification accuracy of a character could be improved by looking at the letters both preceding and following it (Kittler & Foglein, 1984). In this case, common arrangements of the letters (e.g., in English: qu, ee, tion) are used to provide a context within which the character may be interpreted.

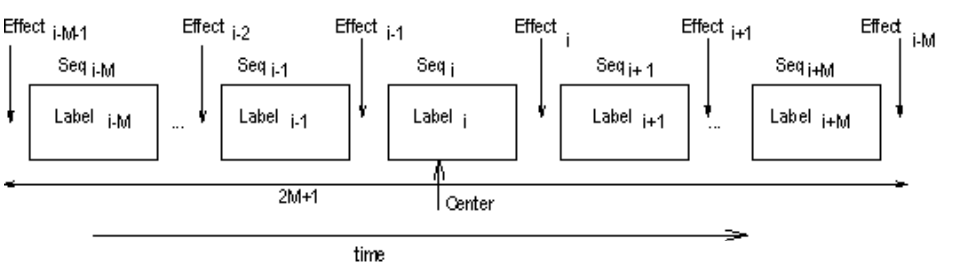
Three examples of algorithms at this level are briefly presented in this section as follows:

1. Probabilistic relaxation (Hummel & Zucker, 1983) is used to characterize a domain like the identification of climax, which has a lot of variation amongst the training samples. In probabilistic relaxation, each shot within the contextual neighborhood is assigned a label with a given probability (or likelihood) by the DBN models. A sliding window is chosen around the center shot. Iterations of the relaxation process update each of the labels around the central shot with respect to a compatibility function between the labels in the contextual neighborhood. In this manner, successive iterations propagate context throughout the timeline. The compatibility function encodes the constraint relationships, such as it is more likely to find a climax scene at a "small" distance from the other climax scene. In other words, the probabilities of both climax scenes are

increased after each pass. The relaxation process is stopped when the number of passes exceeds a fixed value or when the passes do not bring about significant changes to the probabilities.

2. Context cues can also aid in improving the classification accuracy of shots. Consider a CBR system that considers an individual shot or a group of shots (say, 4 to 10), that is, sequence, seq_i. A sequence seq_i is classified into one of the classes (like MTV, soccer, etc.) with $label_i$ on the basis of its low-level and high-level properties. Figure 5 shows the time-layout of sequences with their labels. $Effect_i$ is the transition-effect between seq_i and seq_{i+1}. Consider the 2M neighborhood sequences (in one dimension) of seq_i. The nature of the video domain puts a constraint on defining the constraint relationships within the neighborhood. For example, it is generally not possible to find a tennis shot in between several soccer shots. On the other hand, a few commercial shots may certainly be present in a soccer match. Our strategy to reduce the misclassifications is to slide a window of 2M+1 size over each sequence and check against governing the labels and effects in the neighborhood. If $label_i$ and $label_{i-1}$ are to be different (i.e., there is a change of video class), $effect_i$ should be a special effect (and not a flat-cut), and $label_i$ should match at least a few labels ahead, that is, $label_{i+1}$ and so on. In the second pass, those consecutive items with the same labels are clustered together. A reallotment of the labels is done on the basis of rules, like the length of each clustered sequence should be greater than a minimum value. The second pass can also be used to combine unclassified clustered sequences with appropriate neighboring items. This strategy can also be used to retrieve the entire program. By classifying only the individual shots, retrieval of the entire program is a difficult task. The model can only be built for certain sections of the program. For example, it is not an easy task to model outdoor shots in News, or in-between audience shots in sports. However, through this pass scheme, parts of the same program can also be appropriately combined to form one unit.
3. The goal of the subsequent pass could be to extract information about the media (such as the media being an action movie, thriller movie or an emotional movie), or to construct semantic timelines. For media descriptors like action, the pass involves counting the number of violent scenes, with due consideration to their degrees of violence, which is estimated by the likelihood generated by the DBN model. The pass also considers motion, shot length, and so forth, in the scenes classified as "nonviolent." Constraint conditions are also enhanced during the pass (for instance, the shot length on average is smaller in an action movie than that in a

Figure 5. Subsequent passes perform analysis on the context line of sequences



thriller). The application of constructing semantic timelines is considered in detail in the next section.

Building Larger Models

How DBNs can be made to learn larger models of video is illustrated here. Consider, for example, parsing broadcast news into different sections, and the user is provided with a facility to browse any one of them. Examples of such queries could be "Show me the sport clip which came in the news" and "go to the weather report."

If a video can be segmented into its scene units, the user can more conveniently browse through that video on a scene basis rather than on a shot-by-shot basis, as is commonly done in practice. This allows a significant reduction of information to be conveyed or presented to the user.

Zweig (1998) has shown that a Finite State Automaton (FSA) can be modeled using DBNs. The same idea is explored in the domain of a CBR system. The video programs evolve through a series of distinct processes, each of which is best represented by a separate model. When modeling these processes, it is convenient to create submodels for each stage, and to model the entire process as a composition of atomic parts. By factoring a complex model into a combination of simpler ones, we achieve a combinatorial reduction in the number of models that need to be learned. Thus a probabilistic nondeterministic FSA can be constructed as shown in Mittal and Altman (2003). In the FSA, each of the states represents a stage of development and can be either manually or automatically constructed with a few hours of News program.

Since most video programs begin and end with a specific video sequence (which can be recognized), modeling the entire structure through FSA, which has explicitly defined start and end states, is justified. The probabilistic FSA of News has transitions on the type of shot cut (i.e., dissolve, wipe, etc.) with a probability.

The modeling of the FSA by DBN can be done as follows. The position in the FSA at a specific time is represented by a state variable in the DBN. The DBN transition variable encodes which arc is taken out of the FSA state at any particular time. The number of values the transition variable assumes is equal to the maximum out-degree of any of the states in the FSA. The transition probabilities associated with the arcs in the automaton are reflected in the class probability tables associated with the transition variables in the DBN.

DYNAMIC BAYESIAN NETWORKS

DBNs (Ghahramani, 1997; Nicholson, 1994; Pavlovic, Frey, & Huang, 1999) are a class of graphical, probabilistic models that encode dependencies among sets of random variables evolving in time. They generalize the Hidden Markov Models (HMM) and the Linear dynamical systems by adopting a wider range of topologies and inference algorithms.

DBN has been used to temporally fuse heterogeneous features like face, skin and silence detectors for tackling the problem of speaker detection (Garg et al., 2000; Pavlovic et al., 2000). An important application which demonstrates the potential of DBN is multivariate classification of business cycles in phases (Sondhauss & Weihs, 1999). Modeling a DBN with enough hidden states allows the learning of the patterns of variation shown by each feature in individual video classes (or high-level indices). It can also establish correlations and associations between the features leading to the learning of conditional relationships. Temporal contextual information from temporal neighbors is conveyed to the current classification process via the class transition probabilities. Besides the fact that DBNs were explicitly developed to model temporal domain, the other reason for preferring DBN over time-delay neural networks or modified versions of other learning tools like SVM, and so forth, is

that DBN offers the interpretation in terms of probability that makes it suitable to be part of a larger model.

Structuring the CBR Network

Consider an observation sequence seq_T consisting of feature vectors $F^0, \ldots, F^T$ for $T + 1$ shots (typically seven to 30 shots). Since multiple-label assignment should be allowed in the domain of multimedia indexing (for example, "interesting" + "soccer"), each video class or index is represented by a DBN model. A DBN model of a class is trained with preclassified sequences to extract the characteristic patterns in the features. During the inference phase, each DBN model gives a likelihood measure, and if this exceeds the threshold for the model, the label is assigned to the sequence.

Let the set of n CBR features at time t be represented by $F_1^t, \ldots, F_n^t$ where feature vector $\mathbf{F} \in \mathbf{Z}$, Z is the set of all the observed and hidden variables. The system is modeled as evolving in discrete time steps and is a compact representation for the two time-slice conditional probability distribution $P(Z^{t+1} | Z^t)$. Both the state evolution model and the observation model form a part of the system such that the Markov assumption and the time-invariant assumption hold. The Markov assumption simply states that the future is independent of the past given the present. The time-invariant assumption means that the process is stationary, that is, $P(Z^{t+1} | Z^t)$ is the same for all t, which simplifies the learning process.

A DBN can be expressed in terms of two Bayesian Networks (BN): a prior network BN0, which specifies a distribution over the initial states, and a transition network BN, which represents the transition probability from state Z^t to state Z^{t+1}. Although a DBN defines a distribution over infinite trajectories of states, in practice, reasoning is carried out on a finite time interval 0, . . . , T by "unrolling" the DBN structure into long sequences of BNs over $Z^1, \ldots, Z^T$. In time slice 0, the parents of Z^0 and its conditional probability distributions (CPD) are those specified in the prior network BN_0. In time slice t + 1, the parents of Z^{t+1} and its CPDs are specified in BN_t. Thus, the joint distribution over $Z^1, \ldots, Z$ is

$$P(z^0, \ldots, z^T) = P_{BN_0}(z^0) \prod_{t=1}^{T-1} P_{BN_\rightarrow}(z^{t+1} | z^t)$$

Consider a DBN model and an observation sequence seq_T consisting of feature vectors $F^1, \ldots, F^m$. There are three basic problems of inference, learning and decoding of a model which are useful in a CBR task.

DBN Computational Tasks

The inference problem can be stated as computing the probability $P(\ddot{e} | seq_i)$ such that the observation sequence is produced by the model. The classical solution to the DBN inference is based on the same theory as the forward-backward propagation for HMMs (Rabiner, 1989). The algorithm propagates forward messages at the start of the sequence, gathering evidence along the way. Similar process is used to propagate the backward messages β_t in the reverse direction. The posterior distribution $\ddot{O}^t$ over the states at time t is simply $at(z) \cdot \beta^t(z)$ (with suitable re-normalization). The joint posterior over the states at t and t + 1 is proportional to $\acute{a}_t(z^t) \cdot P_{BN_\rightarrow}(z^{t+1} | z^t) \cdot \beta^{t+1}(z^{t+1}) \cdot P_{BN_\rightarrow}(F^{t+1} | z^{t+1})$.

The learning algorithm for dynamic Bayesian networks follows from the EM algorithm. The goal of sequence decoding in DBN is to find the most likely state sequence Q of hidden variables given the observations such that $X_{*T} = arg \max_{XT} P(X_T | seq_T)$. This task can be achieved by using the Viterbi algorithm (Viterbi, 1967) based on dynamic programming. Decoding attempts to uncover the hidden part of the model and outputs the state sequence that best explains the observations. The previous section presents an application to parse a video program where each state corresponds to a segment of the program.

What Can Be Learned?

An important question that can be raised is this: Which pattern can be learned and which cannot be learnt? Extracting temporal information is complicated. Some of the aspects of the temporal information that we attempt to model are

1. Temporal ordering. Many scene events have precedent-antecedent relationships. For example, as discussed in the sports domain, shots depicting interesting events are generally followed by a replay. These replays can be detected in a domain-independent manner and the shots preceding them can be retrieved, which would typically be the highlights of the sport.
2. Logical constraints could be of the form that event A occurs either before the event B or the event C or later than the event D.
3. Time duration. The time an observation sequence lasts is also learnt. For example, a climax scene is not expected to last over hundreds of shots. Thus, a very-long sequence having feature values (like large number of TTC shots and small shot-lengths) similar to the climax should be classified as nonclimax.
4. Association between variables. For instance, during the building up of a climax, TTC measure should continuously decrease while the motion should increase.

The Problems in Learning

Although DBN can simultaneously work with continuous variables and discrete variables, some characteristic effects, which do not occur often, might not be properly modeled by DBN learning. A case in point is the presence of a black frame at the end of every commercial. Since it is just a spike in a time-frame, DBN associates more meaning to its absence and treats the presence at the end of sequence as "noise". Therefore, we included a binary variable: "presence of a black frame," which takes the value 1 for every frame if at the end of a sequence there is a black frame.

While DBN discovers the temporal correlations of the variables very well, it does not support the modeling of long-range dependencies and aggregate influences from variables evolving at different speeds, which could be a frequent occurrence in a video domain. This solution to the problem is suggested as explicitly searching for violations of the Markov property at widely varying time granularity (Boyen et al., 1999).

Another crucial point to be considered in the design of DBN is the number of hidden states. Insufficient numbers of hidden states would not model all the variables, while an excessive number would generally lead to overlearning. Since, for each video class a separate DBN is employed, the optimization of the number of hidden states is done by trial and test method so as to achieve the best performance on the training data. Since feature extraction on video classes is very inefficient (three frames/second!), we do not have enough data to learn the structure of DBN at present for our application. We assumed a simple DBN structure as shown in Figure 6.

Another characteristic of the DBN learning is that the features which are not relevant to the class have their estimated probability density functions spread out, which can easily be noticed and these features can be removed. For example, there is no significance of the shot-transition length in cricket sequences, and thus this feature can be removed.

Like most of the learning tools, DBN also requires the presence of a few representational training sequences of the model to help extract the rules. For example, just by training the interesting sequences of cricket, the interesting sequences of badminton cannot be extracted. This is because the parameter learning is not generalized enough. DBN is specific in learning the shot-length specific to cricket, along with the length of the special effect (i.e., wipe) used to indicate replay. On the

other hand, a human expert would probably be in a position to generalize these rules.

Of course, this learning strategy of DBN has its own advantages. Consider for example, a sequence of cricket shots (which is noninteresting) having two wipe transitions and the transitions are separated by many flat-cut shots. Since DBN is trained to expect only one to three shots in between two-wipe transitions, it would not recognize this as an interesting shot.

Another practical problem that we faced was to decide the optimum length of shots for DBN learning. If some redundant shots are taken, DBN fails to learn the pattern. For example, in climax application, if we train the DBN only with climax scene, it can perform the classification with good accuracy. However, if we increase the number of shots, the classification accuracy drops. This implies that the training samples should have just enough number of shots to model or characterize the pattern (which at present requires human input).

Modeling video programs is usually tough, as they cannot be mapped to the templates except in exceptional cases. The number of factors which contribute toward variations in the parameters and thus stochastic learning in DBN is highly suitable. We would therefore consider subsequent passes in the next section which takes the initial probability assigned by DBN and tries to improve the classification performance based on the task at hand.

EXPERIMENTS AND APPLICATIONS

For the purpose of experimentation, we recorded sequences from TV using a VCR and grabbed shots in MPEG format. The size of the database was around four hours 30 minutes (details are given in Table 1) from video sequences of different categories. The frame dimension was 352×288.

The principal objective of these experiments is not to demonstrate the computational feasibility of some of the algorithms (for example, TTC or shot detection). Rather we want to demonstrate that the constraints/laws derived from the structure or patterns of interaction between producers and viewers are valid. A few applications are considered to demonstrate the working and effectiveness of the present work.

In order to highlight the contribution of the perceptual-level features and the contextual information discussed in this chapter, other features like color, texture, shape, and so forth, are not employed. The set of features employed is shown in Figure 6. Many works in the past (including ours (Mittal & Cheong, 2003)) have focused on shot classification based on single-shot features like color, intensity variation, and so forth. We believe

News from Singapore TCS Channel 5 ((consist of 2 commercial breaks)	87 '50"
Total	**4 hr 33 min 22 sec**

Figure 6. DBN architecture for the CBR system. The black frame feature has value 1 if the shot ends with black frame and 0 otherwise. It is especially relevant in detection of commercials.

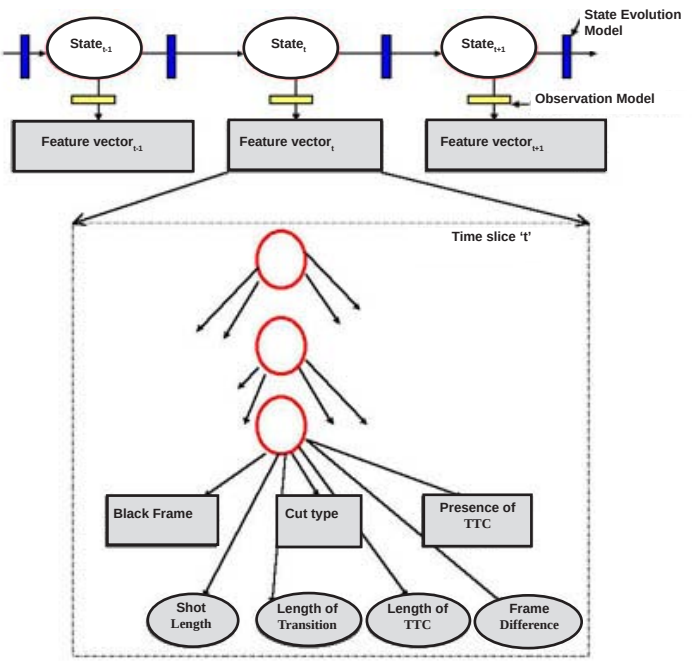

Table 2. Performance: Sequence classifier

Class	Fixed Number of shots		Fixed Number of frames	
	Misclassified (Out of 30)	False alarm (Out of 10 seq. for each class)	Misclassified (Out of 30)	False alarm (Out of 10 seq. for each class)
Commercial (CO)	None	None	3	None
Cricket (CR)	4	3 MT, 1 SO	8	1 MT, 1 NE, 7 SO, 4 TE
MTV (MT)	8	2 NE, 2 TE	11	7 NE, 6 TE, 7 SO
News (NE)	3	None	9	3 TE, 1 SO
Soccer (SO)	10	2 CO, 4 CR, 5 MT, 8 NE, 7 TN	13	1 CO, 1 MT, 4 NE, 9 TE
Tennis (TE)	4	4 MT, 6 NE, 2 SO	13	3 CR, 3 NE, 5 SO
Recall	83.9 %		68.3 %	
Precision	76.7 %		66.5 %	

that since each video class represents structured events unfolding in time, the appropriate class signatures are also present in the temporal domain such as shot-length, motion, TTC, and so forth. For example, though the plots of log shot-length of news, cricket and soccer were very similar, the frequent presence of wipe and high-motion distinguishes cricket and soccer from the news.

Sequence Classifier

As discussed before, the problem of sequence classification is to assign labels from one or more of the classes to the observation sequence, seq_T consisting of feature vectors $F^0, \ldots, F^T$. Table 2 shows the classification performance of the DBN models for six video classes. The experiment was conducted by training each DBN model with pre-classified sequences and testing with unclassified 30 sequences of the same class and 50 sequences of other classes. The DBN models for different classes had a different value of T, which was based on optimization performed during the training phase. The number of shots for DBN model of news was 5 shots, of soccer 8 shots, and of commercials 20 shots. The "news" class consists of all the segments, that is, newscaster shots, outdoor shots, and so forth. The commercial sequences all have a black frame at the end.

There are two paradigms of training the DBN: (i) Through a fixed number of shots (around seven to 10), and (ii) through a fixed number of frames (400 to 700 frames). The first paradigm works better than the second one as is clear from the recall and precision rates. This could be due to two reasons: first, having a fixed number of frames does not yield proper models for classes, and second, the DBN output is in terms of likelihood, which reduces as there are a larger number of shots in a sequence. Large numbers of shots implies more state transitions, and since each transition has probability of less than one, the overall likelihood decreases. Thus, classes with longer shotlengths are favored in the second paradigm, leading to misclassifications.

In general, DBN modeling gave good results for all the classes except soccer. It is interesting to note that commercials and news were detected with very high precision because of the presence of the characteristic black frame and the absence of high-motion, respectively. A large number of fade-in and fade-out effects are present in the MTV and commercial classes, and dissolves and wipes are frequently present in sports. The black frame feature also prevents the MTV class being classified as a commercial, though both of them have similar shot lengths and shot transitions.

The poor performance of the soccer class could be explained by the fact that the standard deviations of the DBN parameters corresponding to motion or shot length features were large, signifying that the degree of characterization of the soccer class was poor by features such as shot length. On the other hand, cricket was much more structured, especially with a large number of wipes.

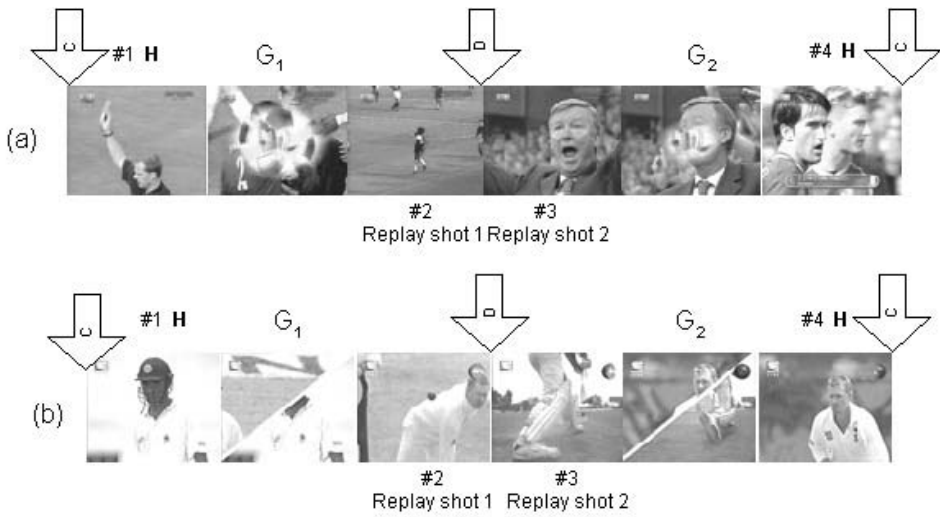
Highlight Extraction

In replays, the following conventions are typically used:

1. Replays are bounded by a pair of identical gradual transitions, which can either be a pair of wipes or a pair of dissolves.
2. Cuts and dissolves are the only transition types allowed between two successive shots during a replay. Figure 7 shows two interesting scenes from the soccer and cricket videos. Figure 7(a) shows a soccer match in which the player touched the football with his arm. A cut to a close-up of the referee showing a yellow card is used. A wipe is employed in the beginning of the replay, showing how the player touched the ball. A dissolve is used for showing the expression of the manager of the team, followed by a wipe to indicate the end of the replay. Finally, a close-up view of the player who received the yellow card is shown.

For the purpose of experiments, only two sports, cricket and soccer, were considered, although the same idea can be extended to most of the sports, if not all. This is because the interesting scene analysis is based on detecting the replays, the structure of which is the same for most sports.

Figure 7. Typical formats of the transition effects used in the replay sequences of (a) soccer match (b) cricket match



Below is a typical format of the transition effects around an interesting shot in cricket and soccer.

$\alpha E . \rightarrow C \rightarrow G1 \rightarrow . \beta\ E \rightarrow G2 \rightarrow E$
where,
E €{Cut, Dissolve}
C € {Cut}
G1, G2 € {Wipe, Dissolve}, G1 and G2 are the gradual transitions before and after the replay
D € {Dissolve}
α, β, γ *€{Natural number}*
$\rightarrow$ *is a ' followed by operator.*

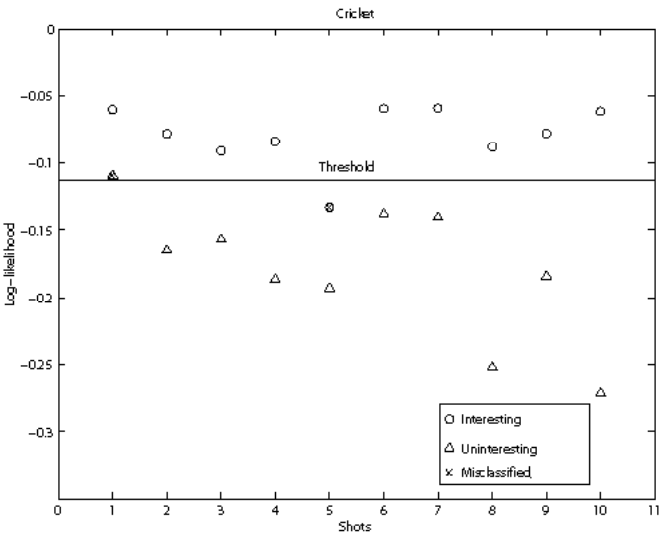
This special structure of replay is used for identifying interesting shots. The training sequence for both sports, which was typically 5 to 7 shots, consisted of interesting shots followed by the replays. Figure 8 shows the classification performance of DBN for highlight extraction. A threshold could be chosen on the likelihood returned by DBN based on training data (such that the threshold is less than the likelihood of most of the training sequences). All sequences possessing a likelihood more than the threshold of a DBN model are assigned an "interesting" class label. Figure 8 shows that only two misclassifications result with the testing. One recommendation could be to lower the threshold such that no interesting sequences are missed; although a few uninteresting sequences may also be labeled and retrieved to the user. Once an interesting scene is identified, the replays are removed before presenting it to the user.

An interesting detail in this application is that one might want to show the scoreboard during the extraction of highlights (scoreboards are generally preceded and followed by many dissolves). DBN can encode in its learning both the previous model of the shot followed by a replay and the scoreboard sequences with their characteristics.

Climax Characterization and Censoring Violence

Climax is the culmination of a gradual building up of tempo of events, such as chase scenes, which end up typically in violence or in passive events. Generally, a movie with a lot of climax scenes is

Figure 8. Classification performance for highlight extraction



classified as a "thriller" while a movie which has more violence scenes is classified as "action." Sequences from "thriller" or "action" movies could be used to train a DBN model, which can learn about the climax or violence structures easily. This application can be used to present a trailer to the user, or to classify the movie into different media categories and restrict the presentation of media to only acceptable scenes.

Over the last two decades, a large body of literature has linked the exposure to violent television with increased physical aggressiveness among children and violent criminal behavior (Kopel, 1995, p. 17; Centerwall, 1989). A modeling of the censoring process can be done to restrict access to media containing violence. Motion alone is insufficient to characterize violence, as many acceptable classes (especially sports like car racing, etc.) also possess high motion. On the other hand, shot-length and especially TTC are highly relevant due to the fact that the camera is generally at a short distance during violence (thus the movements of the actors yield impression of impending collisions). The cutting rate is also high, as many perspectives are generally covered. The set of the features used, though, remains the same as a sequence classifier application. Figure 10 shows a few images from a violent scene of a movie.

Figure 9 shows the classification performance for a censoring application. For each sequence in the training and test database, the opinions of three judges were sought in terms of one of the three categories: "violent", "nonviolent" and "cannot say." Majority voting was used to decide if a sequence is violent. The test samples were from sports, MTV, commercials and action movies. Figure 9 shows that while the violent scenes were correctly detected, two MTV shots were misclassified as "violent." For one sequence of these MTV sequences, the opinion of two judges was "cannot say," while the third one classified it as "violent" (Figure 11). The other sequence consisted of too many objects near to the camera with a large cutting rate although it should be classified as "nonviolent."

Figure 9. Classification performance for violence detection

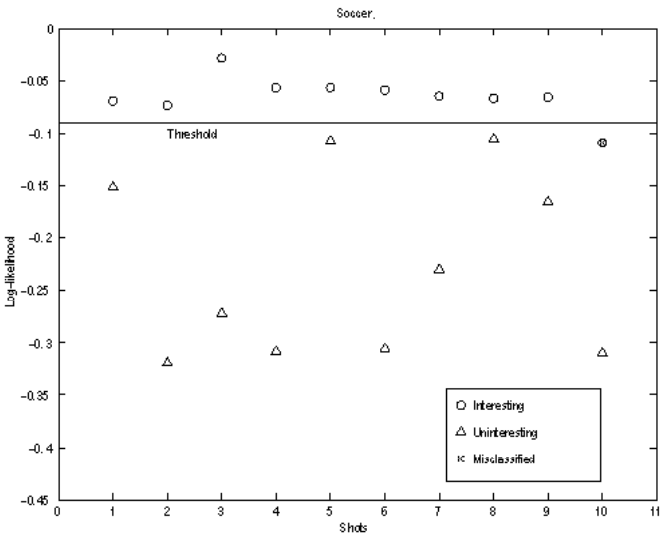


Figure 10. A violent scene that needs to be censored

Figure 11. An MTV scene which was misclassified as violent. There are many moving objects near the camera and the cutting rate is high.

DISCUSSION AND CONCLUSION

In this chapter, the integration of temporal context information and the modeling of this information through DBN framework were considered. Modeling through DBN removes the cumbersome task of manually designing a rule-based system. The design of such a rule-based system would have to be based on the low-level details, such as thresholding; besides, many temporal structures are difficult to observe but could be extracted by automatic learning approaches. DBN assignment of the initial labels on the data prepares it for the subsequent passes, where expert knowledge could be used without much difficulty.

The experiments conducted in this chapter employed a few perceptual-level features. The temporal properties of such features are more readily understood than low-level features. Though the inclusion of low-level features could enhance the characterization of the categories, it would raise the important issue of dealing with the high-dimensionality of the feature-space in the temporal domain. Thus, the extraction of information, which involves learning, decoding and inference, would require stronger and more efficient algorithms.

Chapter 2.15
Design Principles for Active Audio and Video Fingerprinting

Martin Steinebach
Fraunhofer IPSI, Germany

Jana Dittmann
Otto-von-Guericke-University Magdeburg, Germany

ABSTRACT

Active fingerprinting combines digital media watermarking and codes for collusion-secure customer identification. This requires specialized strategies for watermark embedding to lessen the thread of attacks like marked media comparison or mixing. We introduce basic technologies for fingerprinting and digital watermarking and possible attacks against active fingerprinting. Based on this, we provide test results, discuss the consequences and suggest an optimized embedding method for audio fingerprinting.

INTRODUCTION

Robust digital watermarking is the enabling technology for a number of approaches related to copyright protection mechanisms: Proof of ownership on copyrighted material, detection of the originator of illegally made copies and monitoring the usage of the copyrighted multimedia data are typical examples where watermarking is applied. A general overview about digital watermarking can be found in a variety of existing publications, for example in Cox, Miller and Bloom (2002) or Dittmann, Wohlmacher and Nahrstedt (2001).

While stopping the reproduction of illegal copies may be the first goal for copyright holders, discouraging pirates from distributing copies is the more realistic goal today. It can be observed that current copy protection or digital rights management systems tend to fail in stopping pirates (Pfitzmann, Federrath, & Kuhn, 2002). One important reason for this is the fact that media data usually leave a controlled digital environment when they are consumed, enabling analogue copies of high quality of material protect with digital mechanisms. Under these circumstances, the challenge is to find the most discouraging method making it especially dangerous for pirates

to distribute copies. Identification of a copyrighted work by embedding a watermark or retrieving a passive fingerprint (Allamanche, Herre, Helmuth, Fröba, Kasten, & Cremer, 2001) is necessary for preventing large-scale production of illegal CD or DVD copies, but does not stop people from distributing single copies or uploading them to file-sharing networks. Here a method that enables the copyright holder to trace an illegal copy to its source would be much more effective, as pirates would loose their anonymity and therefore have to fear detection and punishment.

Embedding unique customer identification as a watermark into data to identify illegal copies of documents is called fingerprinting. Basically, watermarks, labels or codes embedded into multimedia data to enforce copyright must uniquely identify the data as property of the copyright holder. They also must be difficult to be removed, even after various media transformation processes. Thus the goal of a label is to always remain present in the data. Digital fingerprinting, which embeds customer information into the data to enable detection of license infringement, raises the additional problem that we produce different copies for each customer. Attackers can compare several fingerprinted copies to find and destroy the embedded identification string by altering the data in those places where a difference was detected.

In this chapter, we introduce a method for embedding customer identification into multimedia data: Active digital fingerprinting is a combination of robust digital watermarking and the creation of a collision-secure customer vector. In literature we also find the term *collusion secure fingerprinting* or *coalition attack secure fingerprinting.* There is also another mechanism often called fingerprinting in multimedia security, the identification of content with robust hash algorithms; see for example in Haitsma, Kalker and Oostveen (2001). To be able to distinguish both methods, robust hashes are called *passive fingerprinting* and collision-free customer identification watermarks are called *active fingerprinting.* Whenever we write fingerprinting in this chapter, we mean active fingerprinting.

MOTIVATION

To achieve customer identification directly connected to the copy of the media to be protected, embedding a robust watermark with a customer identification number—called ID from hereon—is a first solution. This prevents the removal of the ID in most cases, as watermarking algorithms become robust to most media processing, like lossy compression or DA/AD conversion.

A simple example:

The content provider wants to sell four copies of an audio file to his customers. To be able to trace the source of an illegal distribution of the file, he embeds a different bit sequence in each copy. For customer A, he embeds "00," for B "01," for C "10" and for D "11".

If he finds a copy of the audio file only sold to those four customers, he could try to retrieve the watermark from the copy. As he uses a robust watermarking algorithm, he is able to find the watermark and to identify the source. For example, he detects the watermark "01" and concludes the source is B. In the case of very strong attacks—which would reduce the quality and make the copies less attractive—he may not be able to detect the watermark, but when the copy is of little value, he does not worry about this.

But due to watermarking characteristics, a much more dangerous situation can occur: Imagine A and D know each other and want to distribute illegal copies of the audio file. They know the file is watermarked and have a certain level of understanding regarding this technology. Therefore they compare both copies to each other, showing differences at certain positions. Knowing most watermarking algorithms can be confused

in this way, they now mix both copies, creating a copy consisting of both customers' copies.

This could render the watermarking algorithm unable to detect the watermarking information embedded. The illegal copy would be of good quality but still not traceable. Even worse, this could lead to pointing at a third customer who is innocent: If A's "00" and D's "11" are mixed, depending on the attacking algorithm and the watermarking method, it can happen that "01" or "10" is detected and B or C are accused.

A possible solution to this problem is to embed checksums together with the customer ID, significantly reducing the probability of false accusations, as the randomly generated new watermark will not fit to the checksum and the watermark becomes useless. Still, no customer identification takes place and the attack is successful. Therefore, a collusion-robust method for customer identification is required.

BASIC TECHNOLOGIES

Before we discuss optimisation methods for active digital fingerprinting, we need to provide an overview to customer identification codes and to identify requirements regarding digital watermarking in this scenario.

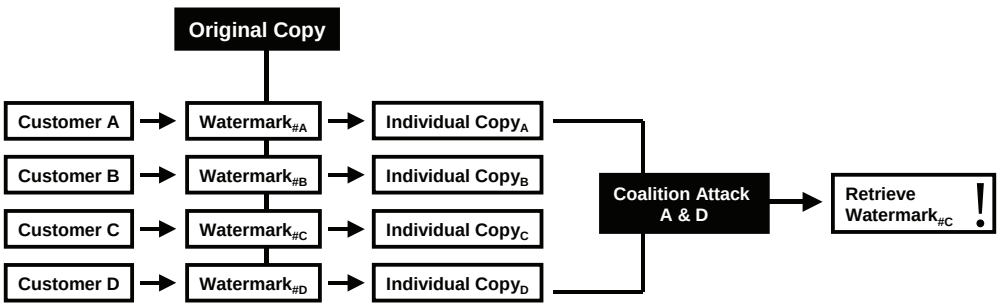
From Dittmann, Behr, Stabenau, Schmitt, Schwenk and Ueberberg (1999), a digital fingerprinting scheme consists of:

- a number of marking positions in the document
- a watermarking embedder to embed letters from a certain alphabet—most often bits—at these marking positions
- a fingerprint generator, which selects the letters to be embedded for each marking position depending on the customer
- a watermarking detector to retrieve a watermark from a marked copy
- a fingerprint interpreter, which outputs at least one customer from the retrieved watermarking information

Different copies of a document containing digital fingerprints differ at most at the marking positions. An attack — as already described — to remove a fingerprint therefore consists of comparing two or more fingerprinted documents and altering these documents randomly in those places where a difference was detected. If three or more documents are compared, a majority decision can be applied to improve this kind of attack: For the area where the documents differ, one will choose the value that is present in most of the documents. The only marking positions the pirates cannot detect are those positions that contain the same letter in all the compared documents. We call the set of these marking positions the intersection of the different fingerprints.

The major challenge of active digital fingerprinting is to create a sequence of bits (or letters)

Figure 1. Coalition attack scheme



that is robust against these comparisons. Even if the attackers can identify differences between their copies, mixing the copies must not lead to a copy in which none of the attackers can be identified.

Active Fingerprinting

To solve the problem of the coalition attack, we use the Boneh-Shaw fingerprint and the Schwenk-Ueberberg fingerprint algorithm (Boneh & Shaw, 1995; Dittmann et al., 1999). Both algorithms offer the possibility to find the customers who have committed the coalition attack. As an application example, we have applied both schemes in a video fingerprinting solution with coalition resistance in Dittmann, Hauer, Vielhauer, Schwenk and Saar (2001) and an analysis of the resistants of audio watermarking in Steinebach, Dittmann and Saar (2002). In the following two subchapters we summarize the two fingerprinting schemes.

Schwenk Fingerprint Scheme

The Schwenk et al. approach (Dittmann et al., 1999) puts the information to trace the pirates into the intersection of up to *d* fingerprints. This allows us in the best case (e.g., automated attacks like computing the average of fingerprinted images) to detect all pirates. In the worst case (removal of individually selected marks), we can detect the pirates with a negligibly small one-sided error probability; that is, we will never accuse innocent customers.

The fingerprint vector is spread over the marking positions. The marking positions for each customer are the same in every customer copy and the intersection of different fingerprints can therefore not be detected. With the remaining marked points, the intersection of all used copies, it is possible to follow up on all customers who have worked together. Another important parameter is the number *n* of copies that can be generated with such a scheme. The scheme uses techniques from finite projective geometry (Beutelspacher & Rosenbaum, 1998; Hirschfeld, 1998) to construct d-detecting fingerprinting schemes with q+1 possible copies. This scheme needs $n=q^d+q^{d-1}+...+q+1$ marking positions in the document. As we see, this can be a huge length and can cause problems with the capacity of the watermarking scheme. The idea to build the customer vector is based on finite geometries and the detailed mathematical background will be provided in the final section.

Boneh-Shaw Fingerprint Scheme

The scheme of Boneh and Shaw (1995) is also used to recognize the coalition attack, but it is another scheme. Here it is noticeable that we do not necessarily find all pirates, with a (any arbitrary small) probability *e* that we get the wrong customer, and each fingerprint has a different number of zeros.

The number of customers is *q* and with *q* and *e* you can get the repeats *d*. The fingerprint vector consists of (*q*-1) blocks of the length d ("d-blocks"), and the total length of the embedded fingerprint computes as *d**(*q*-1). Depending on the repeats the customer vector can be very long and cause problems with the capacity of the watermarking algorithm. The idea to build the fingerprinting vector for each customer is simple: The first customer has the value one in all marked points; for the second customer all marked points without the fist "d-block" are ones; in the third all marked points without the first two "d-blocks" are ones, and so forth. The last customer has the value 0 in all marked points.

With a permutation of the fingerprint vector we get a higher security, because the pirates can find differences between the copies, but they cannot assign it to a special d-block. In the final version we provide the detailed mathematical background.

Digital Watermarking

Digital watermarking is in general a method of embedding information into a cover file. In our case, the cover consists of audio or video files. Depending on the application scenario, the information embedded will differ. Even the basic concept of the watermarking algorithms may change, as there are robust, fragile and invertible watermarking schemes (Cox et al., 2001; Dittmann, 2000; Dittmann et al., 2001; Petticolas & Katzenbeisser, 2000). For copyright protection, usually robust watermarking is applied. Still, numerous requirements need to be identified to adjust a watermarking algorithm to a specific scenario. In this section, we discuss the watermarking requirements with respect to the active fingerprinting application.

Fingerprinting can only take place if the customer is known. This is the case in, for example, Web shop environments, more generally speaking in on-demand-scenarios that require customer authentication. Copies of songs ripped from CDs bought anonymously in stores cannot be marked this way. Embedding a fingerprint in an on-demand situation induces a number of requirements to the watermarking algorithms:

- *Transparency* is a common requirement for marking digital media in e-commerce environments, as the quality of the content acting as a cover for the watermark must not be reduced.
- *Robustness* is necessary against common media operations like lossy compression and format changes.
- *Payload* must be high enough to include the fingerprint, which usually consists of a long bit vector. This can become a critical requirement.
- *Security* is of special importance in this case, as the existence of several copies of the same cover with different embedded fingerprints enables a number of specialized attacks commonly called *coalition attacks.*
- *Complexity* has to be low enough to enable online and real-time marking. A customer who wants to download a song is not willing to stay online for a long time until his or her personalized copy is available. As there will be multiple customers at the same time and media data may have a playing time of an hour or more, either streaming concepts or multiple real-time embedding speed will be necessary. Furthermore, in most cases non-blind methods are suitable where the original is needed during retrieval or detection.
- *Verification* should be performed in a secret environment. The content provider uses a secret watermarking key to embed and retrieve the watermarks. Customers do not know this key as attackers could easily verify their success with it.

This scenario-specific list of parameters shows the difference to common copyright protection environments: While robustness and transparency are of similar interest, in our scenario payload, security and complexity become more important. As active fingerprinting will only be applied if the content provider has to be prepared for attacks against more simple customer identification schemes, security is of special interest. One can assume that specialized attacks against the watermarks will take place. Complexity needs to be low in comparison to embedding a copyright notice, as in active fingerprinting each copy sold needs to be watermarked. This easily can become a bottleneck if the algorithms are not designed accordingly. In general, active fingerprints are much longer than copyright notes, inducing higher payload requirements in our scenario.

To summarize these observations, it becomes clear that not all watermarking algorithms suitable for robust copyright watermarking will be equally suited for active fingerprinting. Only those algorithms that provide high security, high

payload and a low complexity in addition to a high transparency and good robustness may be chosen as a watermarking method.

ADJUSTING WATERMARKING ALGORITHMS TO ACTIVE FINGERPRINTING

To apply active fingerprinting in tracing illegal copies we need a digital watermarking algorithm. Current digital watermarking techniques may embed the generated fingerprinting information redundantly and randomly over the media file. With a random distribution, the intersection of the proposed fingerprints may be destroyed by coalition attacks. Therefore it is important to ensure that one bit with a certain position in the fingerprint vector is always embedded at the same place in the media file for every copy. Only then an intersection is undetectable for an attacker.

Audio Watermarking

To use the properties of the fingerprinting mechanisms to identify the customers who attacked the watermark we build a watermarking scheme with a fixed number of marking positions in each copy of the audio file (Steinebach et al., 2002). These marking positions can be selected based on a secret key and a psycho-acoustic model to find secure and transparent positions. The fingerprinting algorithm generates the fingerprint vector over the binary alphabet {0,1}. The watermarking algorithm embeds this binary vector at the chosen marking positions.

Watermarking algorithms use different methods to embed a message into a cover. The way the message is embedded is relevant for the security of the watermarking and fingerprinting combination: A PCM audio stream consists of a sequence of audio samples over time. Our algorithm uses a group of successive samples, for example, 2048, to embed a single bit of the complete message. Figure 2 illustrates this: The bit sequence 01011 is embedded in a 1-second audio segment by separating the audio into groups of samples and embedding one bit in each of the segments.

This leads to the following situation: If two different bit vectors are embedded in two copies of the same cover with the same key, the two copies differ exactly in those segments where different bits have been embedded as information. Figure 3 shows two embedded bit vectors “01011” and

Figure 2. Audio watermarking over time

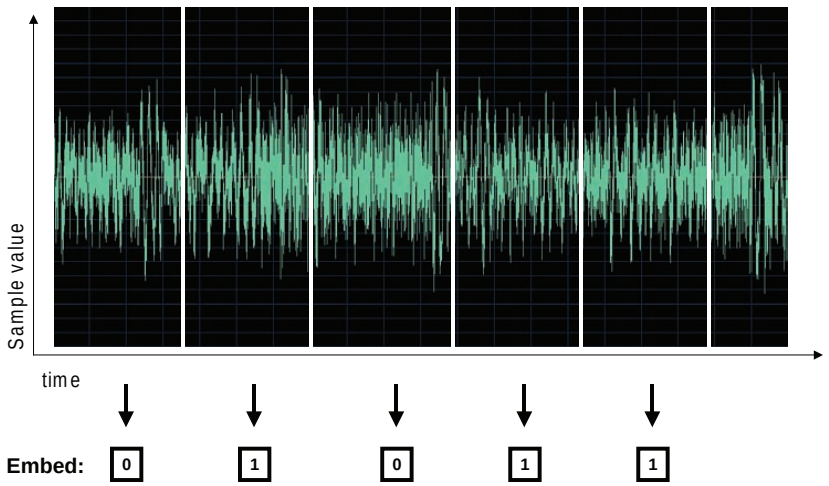


Figure 3. Different embedded bit vectors lead to different segments in the copies

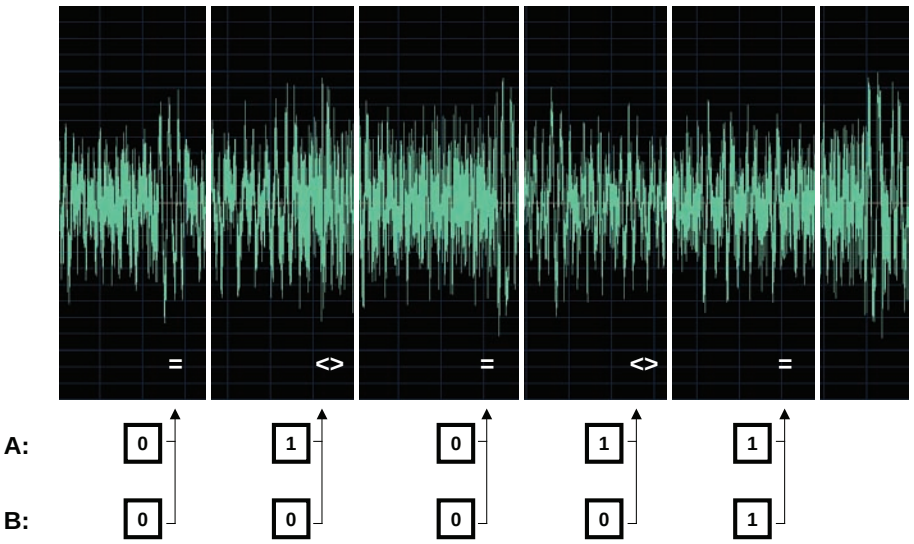


"00001". Both have been embedded in the same cover audio file. If A and B compare their copies, they find equal segments at positions 1, 3 and 5 and different segments at positions 2 and 4.

Video Watermarking

In Dittmann et al. (2001) we have introduced for Schwenk Fingerprint Scheme and the Boneh-Shaw Fingerprint Scheme, a video fingerprinting solution and the coalition resistance. To mark the video, we generate positions within the frame to embed the watermark information (in the video the positions stand for scenes). Each customer has his or her own fingerprint, which contains a number of "1" and "0". Each fingerprint vector is assigned to marking positions in the document to prevent the coalition attack. The only marking positions the pirates cannot detect are those positions that contain the same letter in all the compared documents. We call the set of these marking positions the intersection of the different fingerprints.

Three general problems emerge during the development of the watermark (Dittmann et al., 2001):

- *Robustness.* To improve the robustness against the coalition attack, we embed one fingerprint vector bit in a whole scene. So we reach a resistance against statistical attacks, like average calculation of look alike frames. With this method we can make the frame cutting and frame changing ineffective. We have not contemplated the cutting of a whole scene yet. In the current prototype we mark a group of pictures GOP for one fingerprint bit. We add a pseudo-random sequence to the first AC values of the luminance DCT blocks of an intracoded macroblock in all I-Frames of the video.
- *Capacity.* The basis of the video watermark is an algorithm, which was developed for still images (Dittmann et al., 1999). In still images the whole fingerprint is embedded into the image and the capacity is restricted. With the I-Frame in a video, the capacity is much better. To achieve high robustness, we embed one watermark information bit into a scene. Thus the video must have a minimal length. Additional to the embedding of the watermark, the data rate can increase. The

problem of synchronization between the audio and video stream can arise or data rate is raised. Basically, with the embedding of the watermark we must synchronize the audio and video stream.

- *Transparence*. To improve the transparency we use a visual model. With the visual model the watermark strength is calculated for every marking position individually. Additionally, we use the same marking position for each frame.

DESIGNING ACTIVE FINGERPRINTING ALGORITHMS

Combining customer fingerprints and existing robust watermarking algorithms to provide active fingerprinting is only a first approach to solve the challenge of customer tracking. While existing algorithms may offer parameters to optimise them for this application, new algorithms especially designed for this purpose may lead to superior performance in this domain. In this section, we discuss approaches on digital watermarking algorithm design for active fingerprinting.

Fingerprinting-Optimised Audio Watermarking

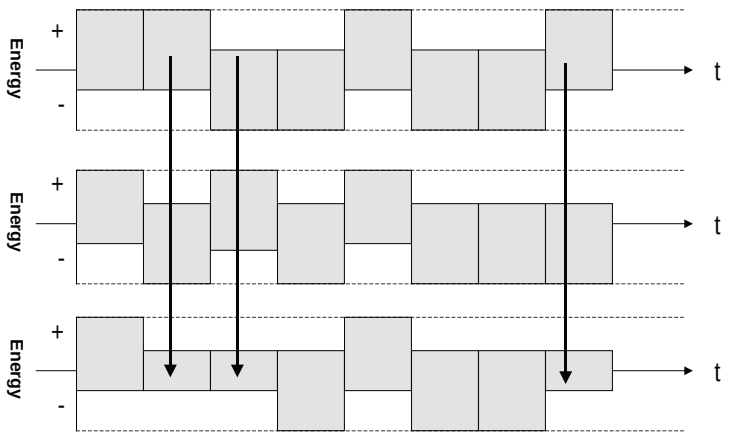
For identifying users that took part in a coalition attack, it could be helpful to change the embedding algorithm so that a rule could be set for mixing two fingerprints. If every time an embedded "0" and "1" are mixed, one specific bit occurs, we would receive a bit vector much more easy to interpret. In the case of the Schwenk algorithm, mixing a "0" and a "1" should always result in a "0" as the "1"s are used to identify the group of attackers.

An example:

The fingerprints A and B differ at position 2 and 5. This leads to 2^2 possible results of a fingerprint attack. Figure 4 shows the reason for this behaviour: Both 0 and 1 are embedded at equal strength. A coalition attack results in traces of both bits at similar strengths at the same position. The watermark detector will therefore have a comparatively random bit at these positions.

After an optimisation for the Schwenk fingerprint the only possible result of a coalition attack with the fingerprints A and B from the example above should be "0010001" identifying both attackers by the shared "1"s at position 3 and 6.

Figure 4. Even-strength watermarking leads to undeterminable results after coalition attacks



At the positions 2 and 5 where the bit values of both fingerprints differ, both times the "0" was dominant in the attack.

This characteristic can be achieved by using different embedding strengths for both bits. In the case of middle or mix attacks this would result in the bit embedded with more strength surviving the coalition attacks. Figure 5 illustrates this concept. Bit values are embedded as a positive or negative energy. Now if we embed a bit, we use more energy for one bit type then the other. When the two energy levels are later mixed by a coalition attack, the energy type embedded with more strength is dominant. For the Schwenk algorithm, the bit 0 would be embedded with more energy then bit 1.

In Figure 5, the positive embedding energy is stronger then the negative one. In the last row the result of a coalition attack is shown: Whenever a positive and a negative energy position is mixed, the result is positive and the retrieved watermarking bit can be predetermined.

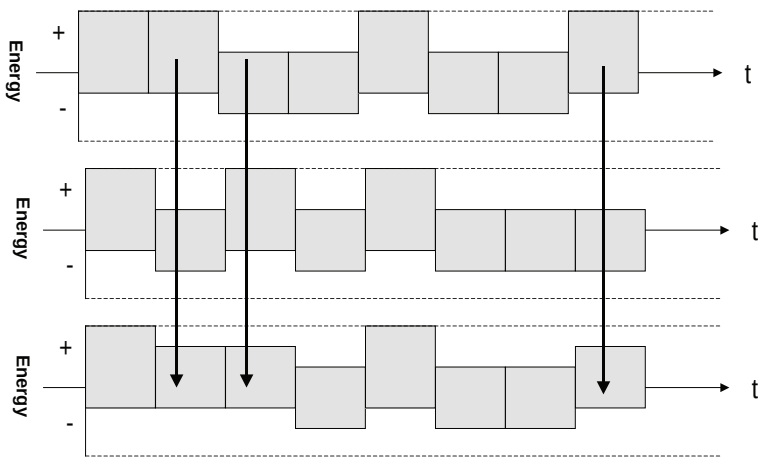
EXAMPLE SCENARIO: CINEMA APPLICATION

Fingerprinting media files today is seen as a promising way of discouraging illegal transfers of copyrighted material. Therefore example scenarios for this technology come from media distribution, especially where a small number of copies exist but leaking of these copies to the public results in major damage.

One appropriate example is the distribution of movies: In recent times copies of movies often happen to be available via Internet as illegal copies before or at the same day they are shown in cinemas. This leads to two possible leaks in distribution:

1. If the movie is available before it is shown in the cinema, some promotional copy of the movie may have been used as a master.
2. If the movie is available right when shown in the cinema, someone may have recorded it with a small video camera.

Figure 5. Different watermarking strengths for 0 and 1 lead to predetermined results after coalition attacks



Tracing illegal copies is more difficult in (2) then in (1). The two leaks strongly differ with regards to the watermarking parameters:

- Robustness in (1) is only necessary against digital video format change if the promotion copy is on DVD, or against high-quality digitisation if the copy is on videotape. Leak (2) requires robustness against a low quality analogue to digital conversion, as the movie is recorded by a small digital camera in a noisy surrounding.
- Transparency, on the other hand, needs to be higher or at least more reliable in (2) than in (1), as a low audio or video quality caused by embedding the watermark will not be accepted by movie theatres and customers.
- The required payload of the watermark may also be higher in (2) than in (1), as one can assume there will be fewer promotional copies than actual movie copies for the cinemas. This leads to more individual customers to be identified by the fingerprints, making them significantly longer.

While, therefore leak (2) may be more challenging then (1), both can be addressed with the same strategy:

- Create a movie master
- Create the required amount of fingerprinted copies from this master
- Distribute the fingerprinted copies
- Search for occurring illegal copies
- Retrieve the fingerprint from the copy
- Identify the leak with the help of the fingerprint

Attacks Against Fingerprinted Copies

As a movie consists of video as well as audio information, watermarking algorithms for both media types can be used for fingerprint embedding. While the watermarking algorithms may be able to satisfy all the scenario-dependent requirements stated above, the fingerprint may also be subject to specialized attacks as soon as it becomes known to the public that fingerprinting is used for tracing copies. This is unavoidable if discouragement is desired.

Let us assume we fingerprint promotional DVDs for tracing leaks (1) using an MPEG video watermark. Two recipients of the promotional copies wanting to distribute illegal copies and willing to work together now can start coalition attacks to remove or corrupt the fingerprints.

The coalition security implies, for example, the following attacks:

(a) Attacks to separate frame areas
(b) Attacks to whole frame
(c) Attacks to whole scenes

The time and practical effort grows from (a) to (c). The video must be split in the important areas. Additionally there must be knowledge about the MPEG video format. The attack over whole frames, like the exchange of frames, is only possible with visually similar frames, because with different frames the semantics of the frames can be destroyed. Only for attacks over whole scenes the watermark has no robustness, because one bit of the fingerprint vector will be cut out. But with the cut off of whole scenes the semantics of the video will be decreased.

Optimisation Potential

To be less vulnerable against coalition attacks, we introduced a strategy for fingerprinting-optimised audio watermarking in this chapter. This strategy can be applied in the cinema-application if a certain loss of audio quality is acceptable, which may be the case in promotional copy distribution.

First test results with embedding the bits 0 and 1 of the audio watermark with different energy are promising. Depending on the energy difference, error rates after coalition attacks are reduced by up to 50%. Error rates have been calculated by counting

the number of times bit 1 has been replaced by bit 0 after a coalition attack.

Figure 6 shows that the reduction of error rates is related to the increase of energy difference between bit 0 and bit 1. If both are embedded at equal strength (0 dB difference), the error rate is above 50%. On the other hand, at a difference of 12 dB, almost no errors occurred.

If the quality loss caused by the strong watermark for bit 1 can be accepted, embedding watermark bits with differing energy seems to be an improvement regarding robustness against coalition attacks. In our example, to reduce the error rate below 10%, we would need an embedding difference of 6 dB, which produces a quality loss similar to mp3 encoding at 192 kbps. This should be acceptable for a huge number of applications.

SUMMARY AND CONCLUSIONS

Altogether, digital watermarking to embed fingerprinting information is a pragmatic approach to discourage the illegal use of the copied data. The wide variety of existing watermarking algorithms reflects the business relevance. Beside the robustness to common media transformations, coalition attacks raise importance and become a critical factor for example in the design of cinema applications. As, for example, a special session "Cinema application" at SPIE 2003 shows, the combination of secure fingerprint schemes and the watermarking algorithms itself seems to be still an open problem. Reasons are in most cases the limited capacity for embedding the collusion secure fingerprint as well as synchronisation problems.

Besides the development of watermarking algorithms and collusion secure fingerprint vector design our future goal is to design interactive tools that strengthen the producers' acceptance to use digital watermarking techniques to offer their data in a more secure way in the digital marketplace.

ABSTRACT

As Web services become more and more popular, how to manage multimedia Web services that can be composed as value-added service solutions remains challenging. This paper presents a service-oriented multimedia componentization model to support Quality of Service (QoS)-centered, device-independent multimedia Web services, which seamlessly incorporates cutting-edge technologies relating to Web services. A multimedia Web service is divided into control flow and data flow. Each can be delivered via different infrastructures and channels. Enhancements are proposed to facilitate Simple Object Access Protocol (SOAP) and Composite Capability/Preference Profiles (CC/PP) protocols to improve their flexibility to serve multimedia Web services. We present a set of experiments that show the viability of our service-oriented componentization model that can support efficient delivery and management of multimedia Web services.

INTRODUCTION

Simply put, a Web service is a programmable Web application that is universally accessible through standard Internet protocols (Ferris, 2003). The rapidly emerging technology of Web services

exhibits the capability of facilitating business-to-business (B2B) collaboration in an unprecedented way. By means of each organization exposing its software services on the Internet and making them universally accessible via standard programmatic interfaces, this Web services paradigm enables and facilitates the sharing of heterogeneous data and software resources among collaborating organizations (Benatallah, 2002). In addition, Web services technology provides a uniform framework to increase cross-language and cross-platform interoperability for distributed computing and resource sharing over the Internet. Furthermore, this paradigm of Web services opens a new cost-effective way of engineering software to quickly aggregate individually published Web services as components into new services. Therefore, the Web services technology has attained significant momentum in both academia and industry.

If the sharable data to be published by a Web service contain multimedia content, which refers to information that seamlessly integrates multiple media types in a synchronized and interactive presentation, the Web service is considered as a multimedia Web service. Multimedia Web services pose new challenges due to the unique characteristics of multimedia data (Khan, 2002). First, the transport of the multimedia information has to meet some Quality of Service (QoS) requirements, such as the synchronization within and among different multimedia data streams or real-time delivery. For example, let us consider a typical Video on Demand (VoD) service, an Internet Kara OK service. It is critical to provide a significant short-response-time service to a VIP customer. In addition, the audio and video information needs to be synchronized on customer's system. Second, the Simple Object Access Protocol (SOAP), the core transport technique of Web services, does not support massive message transport that is imperative for multimedia content transport, or multimedia QoS requirements (Khan, 2002). Third, with the advancement of wireless information appliances, Web service interfaces provide a means to enable the content or service to be created once and accessed by multiple SOAP-enabled [4-6] devices, such as wireless phones (NORTEL), Personal Digital Assistance (PDAs), set-top boxes, as well as regular Web browsers. A Web service is thus considered to be device independent if it can be delivered to different devices (Han, 2000). How to deliver a multimedia Web service to users based upon their possessed devices remains challenging.

In summary, the interoperability of multimedia Web services is not without penalty since the value added by this new Web service paradigm can be largely defeated if a multimedia Web service: (1) cannot guarantee QoS attributes; (2) cannot be transported via the Internet in an organized manner; and (3) cannot be effectively adapted to end devices including mobile devices. In this paper, we present a solution to these existing issues. We accomplish this goal in several ways. First, we propose a separation of control flow and data flow for multimedia Web services, using SOAP to transport the control flow. Second, we propose enhancements to SOAP to serve the transportation of multimedia Web services. Third, we propose enhancements to Composite Capability/Preference Profiles (CC/PP) protocol (CCPP) to provide an easy and flexible way to split and adapt multimedia Web services to appropriate composite devices, and increase the flexibility for users to manage multi-devices. Finally, we propose a service-oriented multimedia componentization model to support device-independent multimedia Web services.

This paper is organized as follows. We first briefly introduce some core techniques of multimedia Web services and related work. Then, we present our solution and we present performance analysis. Finally, we summarize the contributions and innovations, assess limitations and discuss future work directions.

CORE TECHNIQUES OF MULTIMEDIA WEB SERVICES

In this section, we will first briefly introduce the core techniques and standards of multimedia Web services to provide readers with some background context.

Web services typically adopt a provider/broker/requester architectural model (Roy, 2001). A service provider registers Web services at service brokers; a service broker publishes registered services; and a service requester searches Web services from service brokers. The essential aspect of this model is the concept of dynamic invocation: Web services are hosted by service providers, and service requesters dynamically invoke the Web services over the Internet on an on-demand basis.

In order to enable the communications among service providers, service brokers, and service requesters, the paradigm of Web services mainly embraces three core categories of supporting facilities: communication protocols, service descriptions, and service discovery (Roy, 2001). Each category possesses its own *ad hoc* standard. The Simple Object Access Protocol (SOAP) acts as a simple and lightweight protocol for exchanging structured and typed information among Web services. The Web Service Description Language (WSDL) is an XML-based description language that is used to describe the programmatic interfaces of Web services. The Universal Description, Discovery, and Integration (UDDI) standard provides a mechanism to publish, register, and locate Web services. It should be noted that here we adopt a narrow definition of Web services that refers to an implicit definition of SOAP+WSDL+UDDI for the purpose of simplicity. This implies a focus on the management of stand-alone Web services, instead of the compositions of and the interactions among multiple Web services.

As more business organizations adopt Web services technology to publish their sharable data to make their services accessible to more other organizations, it is possible that the data to be published include multimedia information, for example, audio and video. Because multimedia data exhibits unique features that require specific handling (Khan, 2002), it is necessary to examine the existing Web services techniques to better support multimedia Web services. When the SOAP+WSDL+UDDI framework is applied to support a multimedia Web service, two major factors influence the success of a multimedia Web service: (1) the transport of multimedia information over the Web, and (2) the management of composite devices for multimedia contents. Multimedia content caching and streaming are two essential solutions to the first issue (Paknikar et al., 2000). Web caching at a service provider site can largely increase the service provider's ability to support a large amount of service requesters. The streaming paradigm enables a media file be played at the service requester's site while it is being transferred over the Web; therefore, the burden of the service provider can be alleviated. Regarding the latter issue, at the service requester side, multimedia data is normally split over multiple devices with appropriate multimedia capabilities (Han, 2000).

Due to the rapid advancement of wireless information appliances, a Web service will gain more popularity if it is accessible from mobile devices in addition to normal Web browsers, such as wireless phones and Personal Digital Assistance (PDAs) (Pham, Schneider, & Goose, 2000). A Web service is thus considered to be device independent if it can be delivered to different devices (Han, 2000). Several techniques are designed to support the device independence. Based on an Extensible Markup Language (XML) and Resource Description Framework (RDF)-based framework, Composite Capability/Preference Profiles (CC/PP) are proposed to define device capabilities and user preferences so as to manage composite devices (CCPP). The combination of XML and Extensible Stylesheet Language (XSL)

is usually utilized to realize device independence (Kirda, 2001).

RELATED WORK

With the basic background, we proceed to review the related work on multimedia Web services.

Paknikar et al. (2000) define a client-side framework for the caching and streaming of Internet multimedia. The architecture consists of a number of caching proxy servers. A central controlling proxy server called a broker handles all of the initial interactions, and then transfers controls to its sibling proxy servers. This hierarchical structure provides scalability for the proxy servers. Their work also defines a layered replacement policy for caching scaleable encoded video objects. Paknikar et al. predicted that the Real Time Streaming Protocol (RTSP) will become the *de facto* standard for Internet Audio/Video (A/V) caching and streaming.

Pham, Schneider, & Goose (2000) define a *Small Screen/Composite Device (SS/CD)* architecture that supports small screen device-focused communication systems. The key component of the architecture is a Smart Gateway (SG) that distributes multimedia information to the most appropriate composite devices to ensure reliable performances. The critical component of SG is a set of algorithms associated with a Selection-Device-Assignment-Matrix. FieldWise (Fagrell, Forsberg, & Sanneblad, 2000) relies on a server engine to adapt multimedia responses according to the capabilities of the client devices and their network connections. However, these two projects do not adopt the most current Web techniques and standards, such as XML/XSL and CC/PP.

WebSplitter (Han, Perret, & Naghshineh, 2000) provides a unified XML framework supporting multi-device Web browsing. The framework defines an XML-based metadata policy file based on the CC/PP protocol to enable users to specify their access privilege groups. With WebSplitter, all Web pages are constructed as XML files, with pre-defined tags describing mappings to the corresponding access privileges. A proxy is then adopted to split a Web page to different devices. Corresponding XSL style sheets are attached to devices to transform the customized XML to the suitable device-understandable languages. MyXML (Kirda, 2001) is an XML/XSL-based template engine to solve the issue of device independence. The idea is to completely separate the content from its layout information. Similar to the WebSplitter, MyXML utilizes the XML/XSL combination to realize device independence. However, MyXML introduces a whole set of syntax elements that introduces a steep learning curve.

All these efforts concentrate on the client site to facilitate multimedia storage and streaming, to assist multimedia distribution, and to support device independence. At this moment, it appears that there still lacks a generic infrastructure for considering both the client and server sides of multimedia Web services. An additional limitation is that these methods may or may not integrate easily with the most current Web technologies and standards, since Web service is still an emerging paradigm. Here we seek to provide efficient support of delivery and management of multimedia Web services. In contrast with the previous approaches, we accomplish this objective by seamlessly incorporating the cutting-edge techniques of Web services and providing a SOAP-oriented component-based framework to support device-independent multimedia Web services.

SERVICE-ORIENTED COMPONENTIZATION MODEL

In this section, we will introduce our solution to support multimedia Web services. We will first discuss our idea of separation of control flow from data flow to utilize SOAP. Second, we will propose our enhancements to SOAP. Third, we

will propose enhancements to CC/PP protocol. Finally, we will propose our service-oriented multimedia componentization model.

Separation of Control Flow and Data Flow

As a core technique, SOAP is used to transport the content of Web services. However, SOAP was not originally designed to support multimedia Web services; therefore, its current version is not appropriate for streaming multimedia content. The reasons are multi-fold: (1) it is usually infeasible to put a large piece of multimedia content (e.g., a video clip) into one message. However, SOAP does not support message boxcarring and batching (SOAP); therefore, its current version cannot be used to transfer streamed multimedia content. (2) Using SOAP to transport data requires enormous network bandwidth due to its eXtensible Markup Language (XML) markup and protocol overhead (Werner, 2004). Therefore, its performance drawback hinders SOAP from transporting multimedia content that is usually associated with QoS requirements such as response time. (3) Current SOAP specification does not provide facility to define multimedia QoS requirements (Khan, 2002) and multimedia management information such as synchronization signals necessary for time dependent media. In summary, current SOAP is not suitable to transport massive amount of multimedia content.

We do not have to use SOAP to transport multimedia content. There are already a wealth of existing infrastructures, channels, and standards to support the transport of different multimedia content [e.g., MPEG-21 (MPEG-21), SMIL (SMIL), JPEG (JPEG), and HotMedia (HotMedia)]. We can still utilize these existing techniques to transport the content of media files. This, however, still leaves the transport of the multimedia control information?

Our solution is to separate the control information from the content information. The control information may include: (1) meta data that depict the synchronization relationship between multiple media files, (2) QoS requirements, and (3) other control information such as the service provider. Thus transporting a multimedia Web service includes the delivery of both data flow and control flow. The essential advantage is that different transport protocols can be employed to deliver either data flow or control flow, that is, SOAP can be used to transport the control information while traditional multimedia channels can be used to transport the multimedia content in SOAP-specific environment.

This separation of control flow and data flow promises several merits. First, the separation solves the dilemma of transferring multimedia applications into multimedia Web services. Control information will be delivered by SOAP so that different multimedia Web services can interoperate with each other, while multimedia content information can be delivered by traditional multimedia protocols to achieve acceptable performance. Second, the separation provides a loose coupling between control information and content information; thus, the content information can be reused for different Web services. Third, the separation facilitates the tracking and logging of control information so that we can achieve better management and monitoring of multimedia Web services.

Enhancements of SOAP to Support Multimedia Web Services

SOAP has been considered to be a *de facto* communication standard to deliver Web services; however, it was not originally designed particularly to deliver multimedia Web services. First, the nature of multimedia data (Khan, 2002) requires the fact that the transportation of the multimedia information normally has to meet some QoS requirements, such as the synchronization within and among different multimedia data streams or real-time delivery. Consequently, a message

containing multimedia data should carry over its QoS requirements as the guidance for Internet transportation. Nevertheless, the original SOAP specifications do not support this feature. Therefore, we believe that enhancements to SOAP are compulsory in order to facilitate multimedia Web services.

Second, for simplicity, SOAP does not support boxcarring and batching of messages; also it is a one-way protocol (SOAP). There are cases where it is difficult to embed a large multimedia file into one SOAP message. On the contrary, it may be more practical to load a big chunk of information into multiple SOAP messages. Of course there should be a way to identify the relationships among these related SOAP messages. In exceptional cases, some of the media files may not even be suitable to be transferred in SOAP messages; for example, a multimedia segment may need to be transferred in one file with specific file extension. Therefore, special attributes should be provided to identify all of these situations. Although, as we pointed out previously, multimedia information may be transported via channels other than SOAP, nevertheless, for completeness, we still believe that SOAP should be extended with mechanisms to transport multimedia information.

Our enhancements to SOAP can be therefore categorized into two sets: message batching specifications and multimedia QoS specifications. Two sets of attributes are introduced as summarized in *Table 1*; and each of them will be discussed in detail in this section. We first propose a simple workaround of boxcarring and batching of messages to bolster large-scaled multimedia data transportation. A service provider can divide a big message into multiple smaller messages; and these smaller messages altogether conceptually constitute a message box. The service provider can then send these messages to the service requester asynchronously.

As illustrated in the first part of *Figure 1*, several attributes are defined to support this ability: *SenderURL*, *id*, *index*, and *total*. *SenderURL* is defined to specify the unique address of the service provider, so that the service requester knows where to fetch further information if so desired; id is defined to uniquely identify the message box in the domain of the service provider; index is defined to identify the index of the message in the corresponding message box; and total is defined to identify the total number of messages in the message box. These attributes can be utilized to uniquely identify a SOAP message and

Figure 1. A piece of SOAP header message

```
<SOAP-ENV:Envelope

      SOAP-ENV:id=”Msg00001”
      SOAP-ENV:index=”1”
      SOAP-ENV:total=”5”/>
      <SOAP-ENV:Body>
         <m:Metadata>
              <component>Msg00001”</component>
              <component>Msg00002”</component>

              <component>Msg00003”</component>
              <component>Msg00004”</component>
              <component>Msg00005”</component>
         </m:Metadata>
       </SOAP-ENV:Body>
….
</SOAP-ENV:Envelope>
```

Table 1. SOAP attributes introduced

Attribute	*Definition*
SenderURL	Unique address of the service provider
id	Uniquely identify the message
index	The index in message box
total	The total number of messages in message box
MustSendBack	Required to be sent back without changes
Metadata	Specify the structure of the message box
component	Specify the messages in the message box

Attribute	*Definition*
reliable	Reliable transportation
realTime	Real-time transportation
unicast	Unicast to specific node
multicast	Multicast to multiple nodes
secure	Secure in the transportation

the relationships between messages. In addition, a global attribute *MustSendBack* is introduced, which can be utilized to specify that the information is required to be sent back to the service provider without any changes. For example, the service requester's profile needs to be sent back along with the result for the proper multimedia distribution.

Employing the metaphor of the envelope in postal delivery, we insert these identification information of the multimedia content into the corresponding SOAP envelope as the first part. Furthermore, the first message in the message box should contain the metadata in its body block, which identifies the structure of messages contained in the message box. Attributes Metadata and component are defined to specify the metadata information. Let us take a piece of a SOAP message as an example, as shown in *Figure 1.*

This SOAP message is the response message to the request "RequestId0001". This request id "RequestId0001" and user profile information "Profile001" must be sent back. We can see that the message is identified by its unique id "Msg00001"; and it is the first of the total five messages in the message box. Metadata records the message ids of all five messages: "Msg0001," "Msg0002," "Msg0003," "Msg0004," and "Msg0005." Therefore, the requester that receives this message would be aware of the remaining four messages, then could schedule to pre-fetch them with specified ids if so desired.

Second, we introduce five global attributes to the SOAP definition in order to enable a SOAP message to carry on its QoS requirements: *reliable*, *realTime*, *unicast*, *multicast*, and *secure*. These five attributes are summarized in the second part of *Table 1.* For an attribute to be set, its keyword-value pair must be present in this envelope block. The *reliable* attribute can be used to indicate whether the SOAP message requires reliable transportation or not. The value of the *reliable* attribute is either "1" or "0." The absence of the *reliable* attribute is semantically equivalent to its presence with a value "0." If a header element is tagged with a *reliable* attribute with a value of

"1," the recipient of that header entry either MUST find a reliable transportation protocol, or MUST fail processing the message.

The *realTime* attribute can be used to indicate whether the SOAP message requires real-time transportation or not. The value of the *realTime* attribute is either "1" or "0." The absence of the *realTime* attribute is semantically equivalent to its presence with a value "0." If a header element is tagged with a *realTime* attribute with a value of "1," the recipient of that header entry either MUST find enough resources to transfer the message right away, or MUST fail processing the message.

The *unicast* attribute can be used to indicate whether the SOAP message is to be unicasted to a specific end point. The value of the *unicast* attribute is either "1" or "0." The absence of the *unicast* attribute is semantically equivalent to its presence with a value "0." If a header element is tagged with a *unicast* attribute with a value of "1," the recipient of that header entry either MUST find a available path to the specified end point node, or MUST fail processing the message.

The *multicast* attribute can be used to indicate whether the SOAP message is to be multicast to multiple users. The value of the multicast attribute is either "1" or "0." The absence of the *multicast* attribute is semantically equivalent to its presence with a value "0." If a header element is tagged with a *multicast* attribute with a value of "1," the recipient of that header entry either MUST find available paths to all specified end-point users, or MUST fail processing the message.

The *secure* attribute can be used to indicate whether the SOAP message has to be kept secure in the process of transportation. The value of the *secure* attribute is either "1" or "0." The absence of the *secure* attribute is semantically equivalent to its presence with a value "0." If a header element is tagged with a secure attribute with a value of "1," the recipient of that header entry either MUST find secure paths to the destination, or MUST fail processing the message.

Figure 2 is another example of a piece of a SOAP message containing some multimedia information. This message needs to be transferred reliably, real-time, and only transferred to one specific end user. This enhancement provides a way for a SOAP message to delineate its QoS requirements, which can be utilized as a guidance of Internet transportation tools to select different paths and transportation protocols so as to increase performance.

Enhancement of CC/PP Supporting Multimedia Web Services

Multimedia Web services normally need to split multimedia data over multiple devices with appropriate multimedia capabilities (Han, Perret, & Naghshineh, 2000). CC/PP specifies an XML and RDF-based framework to help define device capabilities and user preferences so as to manage composite devices (CCPP). We adopt CC/PP to support multimedia Web services for two reasons. One is that CC/PP was designed particularly for describing device capabilities and user preferences. The other one is that CC/PP is built on top of popular XML technology. Utilizing the CC/PP format, every user can create his/her own profile that declares the list of the user's available re-

Figure 2. A second piece of SOAP message example

    …
</SOAP-ENV:Envelope>
```

sources (devices) and preferences about how each resource would be utilized. However, we found that CC/PP definition is too rigid for device capabilities. For instance, one device may be capable of accepting one kind of media information with some simple transformations; and CC/PP does not support this specification. Therefore, we extend CC/PP by enabling transformation description to be added to devices.

With our extension, in a user's profile, every resource is declared as a separate item, such as a WAP phone. Each item comprises of two parts: one is the declaration of the hardware, and the other one is the declaration of the service, or more directly multimedia resource files that the device can receive. *Figure 3* is an example of a piece of an extended-CC/PP profile for a WAP phone.

As shown, the declaration of this WAP phone contains two parts. The first part defines the hardware, such as the device name, the size of the screen, resolution, and etcetera. The second part defines its acceptable multimedia information, such as image, text, WML, and etcetera. However, it can be noticed that the normal HTML code cannot be directly retrieved on this WAP phone. A stylesheet named HTML2WML.xsl needs to be used to transform the receiving HTML code to the WAP-enabled WML code. With this extension, CC/PP protocol becomes more powerful of describing device capabilities.

Proposed Model Supporting Multimedia Web Services

As Roy and Ramanujan (2001) summarized, a three-role model is broadly adopted in the field of Web services: service providers, service brokers, and service requesters. From the perspective of a service requester, there are two key questions: how to find a demanded service, and how to get the service effectively. This paper focuses on the solution to the second question; therefore, service brokers and related issues will not be discussed. The starting point of this paper is that, with the help of service brokers, service requesters have already located the service providers that offer the requested services. Meanwhile, as high-speed local area networks (LANs) have been deployed extensively over the world (Paknikar et al., 2000), users on such LANs normally access Internet through a proxy server that provides caching facility. Therefore, we make another assumption on such a concept, that users always invoke Web services through their proxy server. In addition, due to the fact that service requesters are normally connected from service providers by Internet, it

```

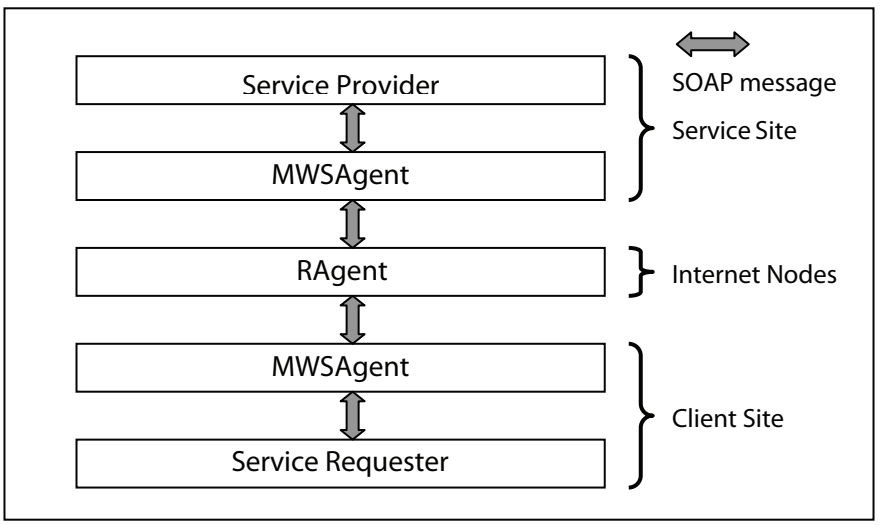
is reasonable to assume that a message has to pass through multiple networks between them. Based on these three assumptions, the problem can be refined as: how to effectively and efficiently support multiple service requesters, who rely on the same proxy server and request the same Web service from the same service provider that is several networks away.

Here we propose a component-based framework as a solution. As illustrated in *Figure 4*, three types of intelligent agents are introduced as the main components of the framework; and SOAP is adopted as the service transportation protocol. The first agent introduced is the Multimedia Web Service Server Agent (MWSSAgent) that locates at service providers; the second one is the Multimedia Web Service Agent (MWSAgent) that locates at proxy servers on the clients' LAN; and the third one is the Routing Agent (Ragent) that locates at intermediate network nodes. *Figure 4* as well implicates the information path of a multimedia Web service on the basis of this framework. When a service requester submits the request, the MWSSAgent handles the request, invokes the corresponding service backend to get the results, equips return SOAP messages, and sends them to the Internet. The RAgent reads the envelopes of the receiving SOAP messages, analyzes their QoS requirements, and selects the appropriate protocols to send to the next proper RAgent or the proxy server. The MWSAgent finally receives the SOAP messages, propagates to the original requester, and distributes the multimedia streams to appropriate media devices, such as Web browsers, audio systems, PDAs, and etcetera. We will discuss each of the three agents in detail in the following sections.

Multimedia Web Services Server Agent (MWSSAgent)

A multimedia Web service may generate a complex result including multiple multimedia files. Disregarding the fact that SOAP currently can only bind to HTTP while HTTP was not designed for streaming media data (Paknikar et al., 2000), it is not efficient and practical to encapsulate all information in one SOAP response message to pass through the Internet, especially when the information may get lost in the process of transportation. With our enhancements to SOAP described in the previous section, a big piece of information

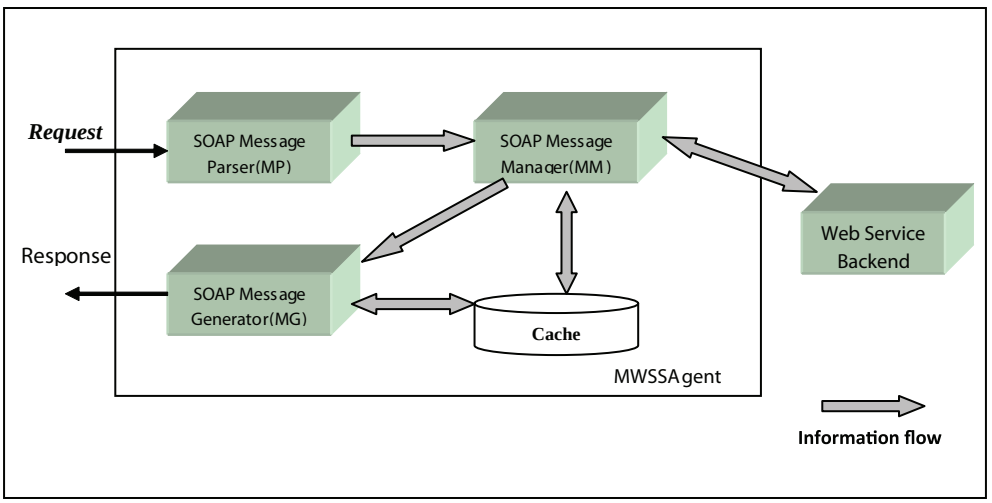
Figure 4. A component-based framework for multimedia Web services



can be separated into multiple interrelated SOAP messages, with the first message containing the metadata and specifying the identification of each message. The metadata is completely separated from the real content. Here the metadata includes the structure of the set of the sub-messages, and the relationships between messages. It is one of the main responsibilities of the WMSSAgent to generate the SOAP response message box from the result provided by the service provider. To avoid aggravating Internet traffic, the response philosophy that the MWSSAgent adopts is a lazy-driven norm, that is, it does not always send back to the service requester all of the messages at the same time; some messages may stay on the MWSSAgent until they are requested particularly. Therefore, the caching facility is necessary to support this philosophy. In addition, published Web service providers normally expect large amount of requests, thus managing and reusing cached messages become essential.

Therefore, we propose the MWSSAgent as an intelligent agent on the service provider site to facilitate multimedia services. Its architecture is illustrated in *Figure 5*, together with the interactions among its components. The architecture contains three functional components — a SOAP message parser (MP), a SOAP message generator (MG), a SOAP message manager (MM), with a local cache. MP is in charge of parsing incoming SOAP request messages, interpreting the requests and forwarding them to MM. MM first checks the cache to see whether the result SOAP messages have already been generated and stored. If the results exist, the MM will send back the results through the MG — the MG needs to generate the corresponding return envelopes based on the requests. If the results are not found, the MM will invoke the service backend for the service. The MG will then generate the full set of SOAP response messages and store to the local cache, before sending back the first response message that includes the metadata. All of the SOAP response messages will be cached on the local disk under the control of the MM. When a SOAP request message arrives, the MP will verify whether the request is the first request for a service, or a subsequent request for a specific response message of a particular service. When the MG generates the set of response messages, all messages will be uniquely numbered for identification purposes. Owing to the fact that a service requester may invoke a specific SOAP message later on, the full set of SOAP messages corresponding to a Web

Figure 5. MWSSAgent architecture



service will either be all stored in the cache of the MWSSAgent, or fully swapped out when storage limitation is encountered. Here we adopt the caching and streaming algorithms introduced in Paknikar et al. (2000).

Multimedia Web Services Agent (MWSAgent)

We propose a MWSAgent as an intelligent agent on the proxy server at the client site to support multimedia Web services. The component-based architecture is illustrated in *Figure 6*. The MWSAgent comprises of four functional components: service broker, a user profile manager, a service delivery manager, and a multimedia manager. In addition, there are three caches contained in a MWSAgent: one for user profiles, one for request-profile mapping, and one for multimedia information.

User Profile Manager (UPM)

The User Profile Manager (UPM) registers user profiles and stores them in the user profiles cache. Adopting our extended CC/PP protocol as discussed in the previous section, a user profile declares the list of the user's available resources and the user's preferences about how each resource would be utilized. UPM assigns a unique id to every registered profile, so that one user can possess multiple profiles for the purposes of different Web services. When a user requests a Web service, she is required to specify which profile she wishes to use to receive the service. The service broker will assign a unique id to each request; and the UPM will store the 2-tuple (request id, profile id) in the cache of request-profile mapping. This 2-tuple will also be included in the SOAP message of the service request as *MustSendBack*. Therefore, when the response comes in, the UPM will use the sent-back (request id, profile id) pair to pick up the stored corresponding profile from the profile cache. Users are allowed to change their profiles, add new profiles, or delete some profiles. The granularity of the definition of a profile depends on the power of CC/PP and RDF vocabulary.

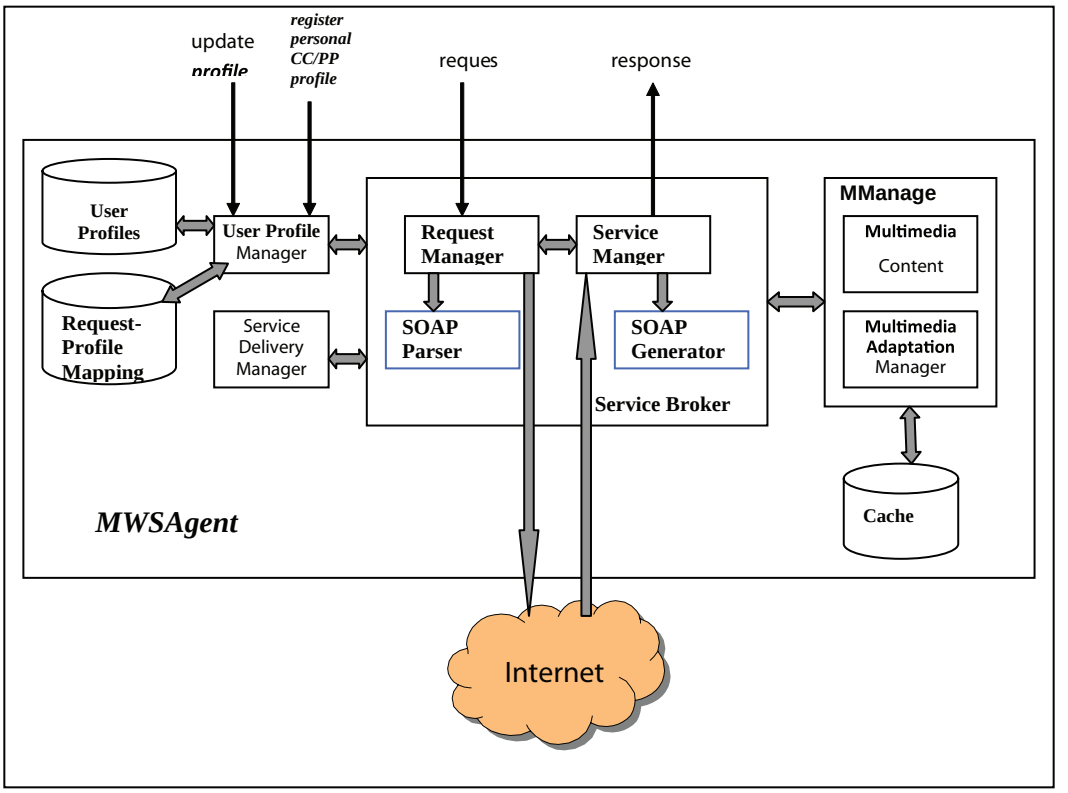
Multimedia Manager (MManager)

The Multimedia Manager (MManager) contains two sub-components: the Multimedia Content Manager (MCM) and the Multimedia Adaptation Manager (MAM). The MCM manages the caching of multimedia SOAP response messages on the local disk of the proxy server. The MAM handles media adaptation if necessary, in order to achieve device independence. In some cases when the destination device is not capable of handling requested multimedia contents, the MAM may convert the media accordingly. In some other cases, the destination device may announce that it is able to receive some media contents after some adaptations are performed. For instance, a WAP phone could accept HTML code; however, it needs to be transformed to WML code. In accordance with our extension to the CC/PP, when a user specifies her profile, she can stipulate the transformation algorithm she prefers.

Service Broker

The service broker consists of four sub-components: a request manager, a service manager, a SOAP generator, and a SOAP parser, as shown in *Figure 6*. The SOAP generator generates SOAP request messages; the SOAP parser parses incoming SOAP response messages; and the request manager is a request broker of user requests for Web services. A user may request a Web service that another user from the same LAN has previously requested. Therefore, the request manager will first check the local disk through the MCM. If the result is a hit, the request manager will pass the control to the service manager to send back the information. As a consequence, not only the remote service broker and the service provider will have less traffic, but also the response time

Figure 6. MWSAgent architecture



may be largely shortened. Otherwise, the request manager will assign a unique id to the request, ask UPM to store to the request-profile mapping, and then call the SOAP generator to generate a SOAP request message and send it to the service provider over the Internet. The unique request id and the user profile id will be marked as *MustSendBack* and be sent together with the SOAP request.

The service manager is invoked when a SOAP response comes back from Internet. It will first call the SOAP parser to analyze the content of the result message. If the result contains multimedia information not coming together with the first message, the service manager will schedule to pre-fetch the corresponding rest of media files to enhance the streaming of the media data. All the messages will be sent to the MCM to store in the local disk before sending back to the original requester, so as to achieve caching at the proxy server level. As a result, the service provider might not be even online all the time but its content can still be available at the cache of the MWSAgent. For persistent multimedia data (e.g., a movie), this cached data may be immediately utilized. For time-varying data, however, a mechanism for determining if the data is stale will have to be employed. Consider scalable encoded or layered video information for example: such objects have a "base" layer containing essential information, and one or more "enhanced" layers containing higher level information (Paknikar et al., 2000). The service manager will try to download the sub-nodes following the layers. It will attempt to download the lower layers before downloading higher and more enhanced layers. Meanwhile, the service manager will work with the UPM to launch the corresponding user profile. And then the control will be passed to SDM to deliver the result to the original service requester.

Service Delivery Manager (SDM)

The Service Delivery Manager (SDM) decides the priority and the order of the services to be sent back to the requesters, and decides how to split the returning information to appropriate devices if there are multiple devices. A set of criteria is kept at the SDM to be utilized to optimize the order of the delivery, such as request time, request priority, current available resources, and etcetera. The details of the algorithms of the selection and adaptation will not be discussed in this paper.

Route Agent (RAgent)

SOAP messages are adopted to transfer requests and responses through the Internet between a MWSSAgent and a MWSAgent. A SOAP message in this paper contains multimedia information that normally possesses QoS requirements. As discussed in the previous section, a SOAP message may have to travel through several heterogeneous intermediate networks before it finally reaches the MWSAgent. Each of these heterogeneous networks could support multiple protocols and the flexibility of selecting protocols dynamically (Banchs et al., 1998). Therefore, in order to satisfy the performance requirements of the multimedia SOAP message to be transported, each network may need to select the most appropriate network protocol. For example, a NACK-reliable multicast protocol (Floyd et al., 1997) should be adopted on an ATM network in order to increase performance. We propose the RAgent to achieve this goal. A RAgent resides at an intermediate network node on the Internet. Generally we suggest that each active network install a RAgent as the high-level director of the network routing. For a legacy system network that does not install RAgent, SOAP messages can be passed without looking at the information it carries.

This paper focuses on the selection of protocols to increase the performance of network transport rather than the selection of path-routing algorithms. The architecture of a RAgent is composed of four sub-components, as illustrated in *Figure 7*. The SOAP parser is responsible for parsing incoming SOAP messages, determining the QoS requirements, and passing them to the Protocol Manager (PM). The PM receives QoS requirements, searches the Protocol Pool (PP), and locate the appropriate protocol to use. The PP is the interface encapsulating all protocols registered in the corresponding network. The Protocol Registration Manager (PRM) handles the registration of new protocols to the network or removal of some protocols. Under the PP are two sub-components: a cache of the registered protocols, and an abstract matrix that records the protocols and their QoS characteristics, such as reliability, real-time, security. The PRM maintains the abstract matrix when a new protocol is registered to the PP or removed from the PP.

When the PRM registers a new protocol to the protocol pool, it not only records its QoS properties, but also its cost. Typically, the cost here refers to the efficiency of the protocol. The more reliable a protocol is, the more costly it will be. For example, TCP is more costly than UDP because of the acknowledgment requirement. *Table 2* is an example of the abstract protocol matrix. Three protocols are registered into the protocol pool: TCP, UDP, and NACKRMP. TCP and NACKRMP are reliable protocols, while NACKRMP is a real-time protocol. TCP and UDP can be used for unicasting to a single node, while TCP, UDP, and NACKRMP can all be adopted for the purpose of multicasting. From *Table 2* we can also conclude that TCP is more costly than UDP; and NACKRMP costs the most.

PERFORMANCE EVALUATION

The goal of our experiments is to design and conduct a simulation to evaluate the performance of our framework in a typical multimedia Web service application. The application we selected

Figure 7. RAgent architecture

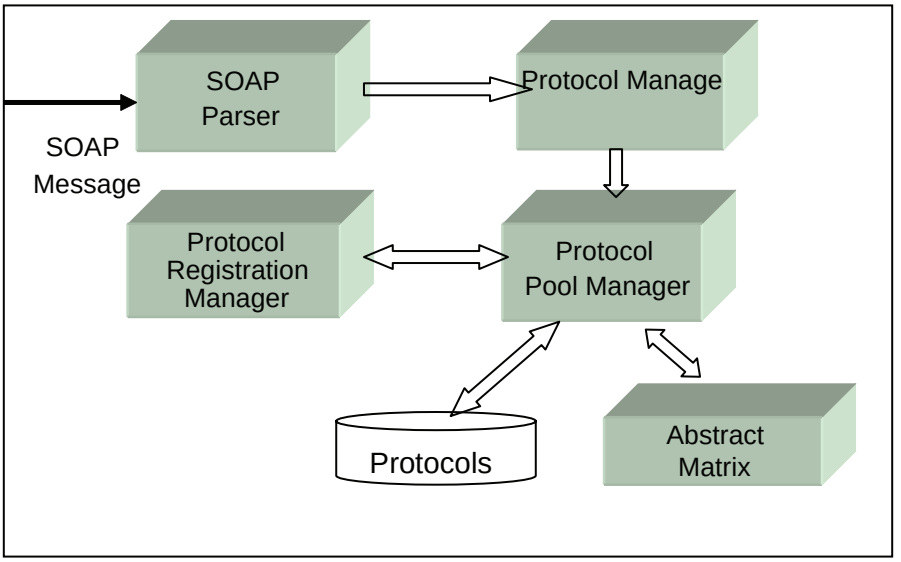


Table 2. Example of abstract protocol matrix

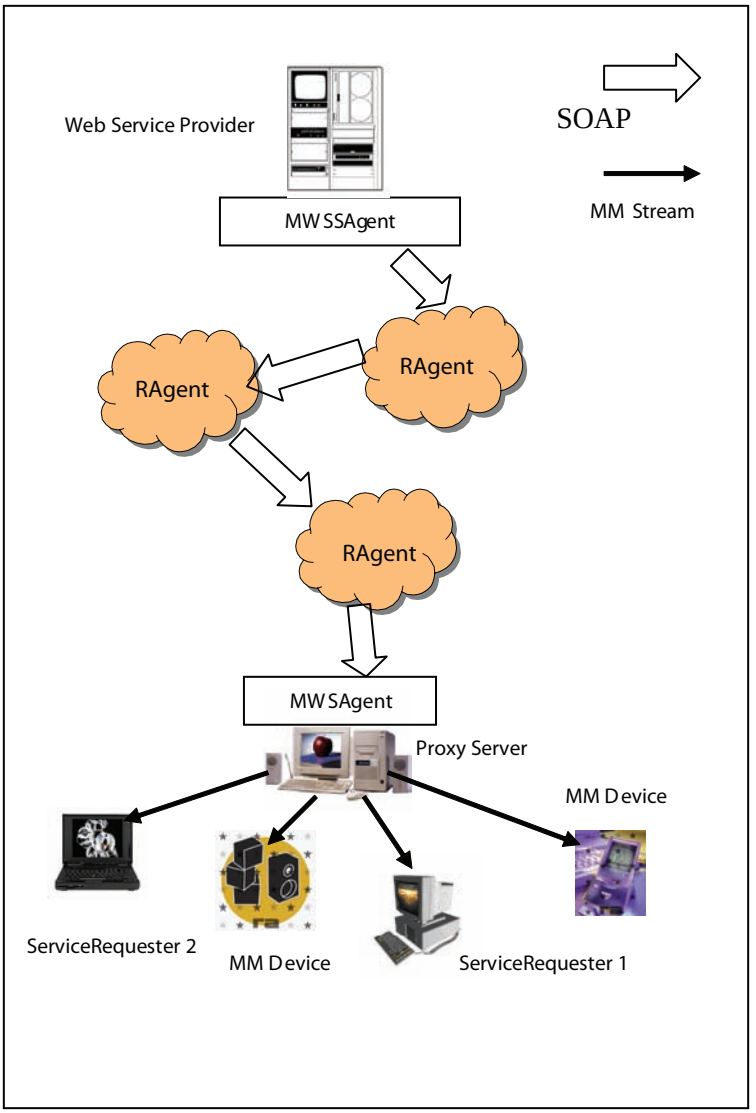
Protocol	*TCP*	*UDP*	*NACKRMP*
Reliability	**X**		**X**
Security			
Real-time		**X**	**X**
Uni-cast	**X**	**X**	
Multi-cast	**X**	**X**	
Cost	**4**	**1**	**5**

to implement is a distance-learning environment: multiple students request multimedia course information from servers. In such an application, one may assume that the students will be congregated at a set of proxy servers, and will be accessing a common set of material. Hence, we want to vary the number of service requesters and proxy servers, holding the other system components constant. To reflect this requirement, we design the experiment based on the following assumptions. First, we assume that there is only one service provided by the system, and there is only one server machine that provides the service. Second, we assume that multiple students who reside on the same LAN request the service through one common proxy server. Third, we assume that there are three networks between the server and the proxy server: Ethernet and ATM and then Ethernet. A message from the server machine has to first pass through these three networks in the order specified before it hits the proxy server. Ethernet has TCP and is NACK RMP (Floyd et al., 1997) registered; and the ATM network has UDP and is NACK RMP registered. Suppose we require real-time QoS multimedia transportation. Fourth, we assume that the transportation time between a service requester and its corresponding proxy server is ignored due to the fact that they reside on the same LAN. Therefore, the problem is simplified and refined as shown in

Figure 8. One server machine stores all of the course information and serves as the service provider; and multiple students request the same course information from this server machine as service requesters. Each student may possess one computer and some multimedia devices, such as speakers or cell phones. All students reside on the same LAN and communicate to the service provider through a proxy server machine.

We set up the experimental environment as shown in *Figure 8*. The multimedia Web service is implemented as a normal J2EE-compatible Web application on the JRun application server (JRun). One MWSSAgent is installed on the server; and one MWSAgent is installed on the proxy server. Each of the three networks has one machine that applies RAgent. All of the three types of agents are implemented in Java. Both MWSSAgent and MWSAgent are also implemented as J2EE-compatible server on the JRun application server (JRun). The SOAP parsers and generators on all three agents are implemented by modifying the

Figure 8. An example applying framework



open source Apache Axis system (Axis). According to our experimental setup, the two RAgents in the Ethernet will choose TCP, and the RAgent in the ATM network will choose UDP to increase the performance.

We design the experiment such that each client would create threads and then communicate with the server, requesting multimedia services. We perform tests on the server machine applying a

MWSSAgent and without a MWSSAgent. Moreover, we performed the same set of tests on the service with one SOAP message (980KB) and two SOAP messages (980KB each). For our experimentation we performed very low contention (1 client), low contention (2,4 clients), moderately low contention (6,8 clients), moderately high contention (10,12,14 clients), and high contention (16,18 clients). For each client, we record the response time, from the time the thread starts the request to the time the entire multimedia information is received. Then the response time from all clients were averaged. The results performed on the four sets of situations are shown in *Figure 9*. Each point in the figure shows the averaged response time measured in seconds when there are specific numbers of clients requesting the service. From the figure, it shows that the system applying MWSSAgent outperforms the system without it. The higher number of clients the system supports, the higher the performance the MWSSAgent exhibits. *Figure 9* also shows that the more clients a service provider needs to support, the higher efficiency our framework exhibits. Only when there is one client who requests a service, the system applying the MWSSAgent takes longer because of the extra operation time spent on the MWSSAgent. However, the benefits justify this extra work as long as there are multiple requesters.

To test the effectiveness and efficiency of applying the MWSAgent, we relax one assumption from the first experiment, so that there are two proxy servers in the experimental system, and clients are averagely distributed behind these two proxy servers. We apply the MWSAgent on each of the proxy servers. The results performed on the same four sets of situations are illustrated in *Figure 10*. The approach to measure the results is the same as that of the first experiment. The figure shows that the system applying MWSAgent outperforms the system without it. *Figure 10* shows

Figure 9. One-proxy performance

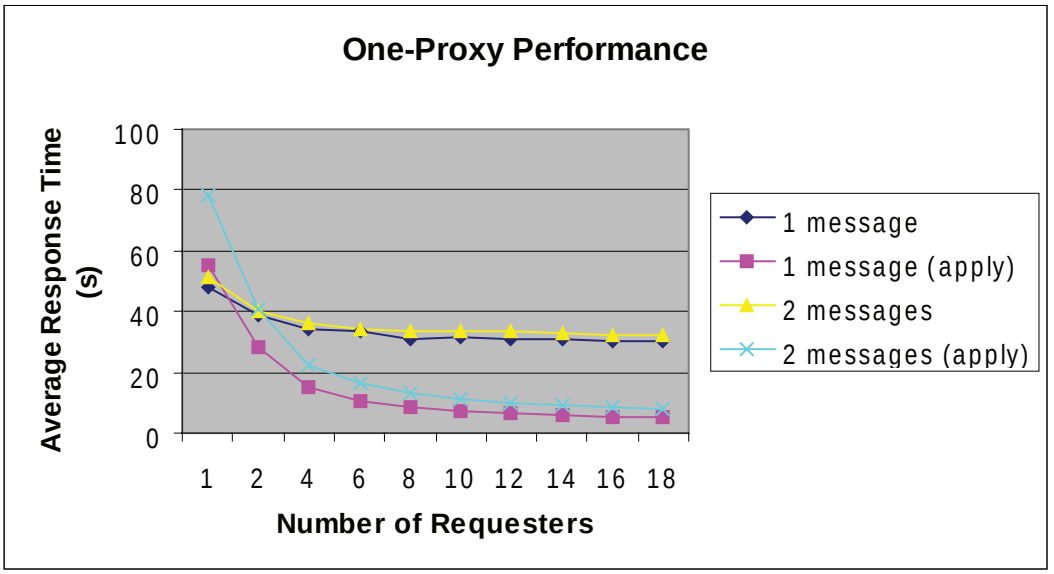


Figure 10. Two-proxy performance

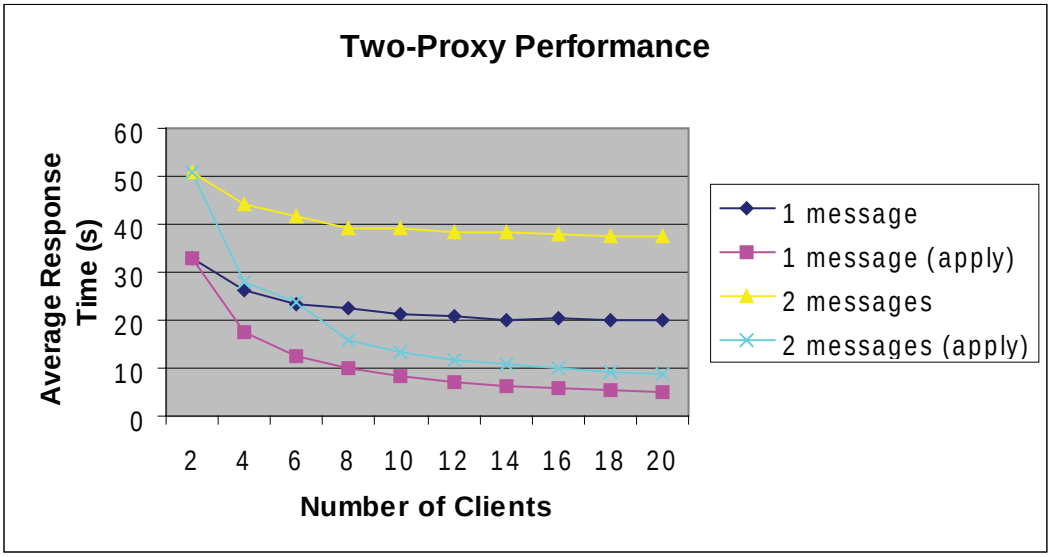

that the more clients sharing one proxy server, the higher efficiency the MWSAgent exhibits. It also shows that when there is only one client behind of a proxy server, the system applying the MWSAgent takes longer because of the extra operation time overhead spent on the MWSAgent. However, again, the benefits justify this extra work as long as there are multiple requesters.

These two experiments show that our framework exhibits the distinct advantage of facilitating a multimedia Web service provider to support larger amounts of Internet clients, and shortening the average response time for service requesters.

ASSESSMENTS, INNOVATIONS AND FUTURE WORK

We present in this paper a service-oriented componentization model to support device-independent multimedia Web services. In the current infrastructure, we adopt caching and replacement algorithms introduced in Paknikar et al. (2000) for both the MWSAgent and the MWSSAgent. Since these two agents serve different purposes, using the same set of caching and replacement algorithms may not be most efficient. In addition, this paper concentrates on protocol selection and dynamic binding, based on the QoS requirements carried by SOAP messages, on networks to support multimedia QoS requirements. To guarantee multimedia QoS requests, efficient routing algorithms are inevitable. Many challenging issues remain in the realm of multimedia Web service. The framework proposed in this paper is based on a much simplified problem domain.

Despite these limitations that could be improved upon or resolved by further work, our model extends research on multimedia Web services in several ways. First, the SOAP enhancements provide a simple way to improve the ability and flexibility of the *ad hoc* standard SOAP protocol to serve for multimedia Web services, by supporting batch facilities and QoS requirements. Second, the CC/PP enhancements increase the flexibility of the system to manage multi-devices and ensure device independency. Third, three types of intelligent agents are synergistically integrated to form a framework to

support efficient service-oriented multimedia Web services. This model also facilitates caching and streaming of multimedia transport. In addition, our model seamlessly incorporates cutting-edge technologies relating to Web services: SOAP, XML/XSL, and the CC/PP. The result of this research can be applied to the software industry and serves as an architectural design to construct multimedia Web service applications.

We intend to continue our research work in the following directions. First, we will explore efficient caching, replacement, and pre-fetching algorithms so as to improve QoS performance. Second, we will attempt to bind SOAP to other more multimedia-oriented transportation protocols, such as Real Time Streaming Protocol (RTSP). Third, we will investigate QoS routing algorithms on routers to support SOAP QoS requirements. Fourth, we will pursue a formal description language to facilitate protocols to be published on the Web and dynamically registered to networks. Finally, we intend to implement a mechanism to monitor multimedia QoS performances over different networks.

Section 3

Tools and Technologies

This section presents extensive coverage of the interaction between multimedia and the various tools and technologies that researchers, practitioners, and students alike can implement in their daily lives. These chapters provide an in-depth analysis of mobile multimedia, while also providing insight into new and upcoming technologies, theories, and instruments that will soon be commonplace. Within these rigorously researched chapters, readers are presented with countless examples of the tools that facilitate the transmission of multimedia data. In addition, the successful implementation and resulting impact of these various tools and technologies are discussed within this collection of chapters.

INTRODUCTION

Multimedia: Promises and Challenges

In recent years, the rapid expansion of multimedia applications, partly due to the exponential growth of the Internet, has proliferated over the daily life of Internet users. Consequently, research on multimedia technologies is of increasing importance in computer society. In contrast with traditional text-based systems, multimedia applications usually incorporate much more powerful descriptions of human thought – video, audio and images (Auffret, Foote, Li & Shahraray, 1999). Moreover, the large collections of data in multimedia systems make it possible to resolve more complex data operations, such as imprecise query or content-based retrieval. For instance, image database systems may accept an example picture and return the most similar images of the example (Cox, Miller & Minka, 2000, Huang, Chang & Huang, 2003). However, the conveniences of multimedia applications come at the expense of new challenges to the existing data management schemes:

- Multimedia applications generally require more resources; however, the storage space and processing power are limited in many practical systems; for example, mobile devices and wireless networks (Lim & Hurson, 2002). Due to the large size of multimedia databases and complicated operations of multimedia applications, new methods are needed to facilitate efficient accessing and processing of multimedia data while considering the technological constraints (Bourgeois, Mory & Spies, 2003).
- There is a gap between user perception and physical representation of multimedia data. Users often browse and desire to access multimedia data at the object level ("entities" such as human beings, animals or buildings). However, the existing multimedia-retrieval systems tend to represent multimedia data based on their lower-level features ("characteristics" such as color patterns and textures), with less emphases on combining these features into objects (Hsu, Chua & Pung, 2000). This representation gap often leads to unexpected retrieval

results. The representation of multimedia data according to a human's perspective is one of the focuses in recent research activities; however, no existing systems provide automated identification or classification of objects from general multimedia collections (Kim & Kim, 2002).

- The collections of multimedia data are often diverse and poorly indexed (Huang et al., 2002). In a distributed environment, due to the autonomy and heterogeneity of data sources, multimedia objects are often represented in heterogeneous formats (Kwon, Choi, Bisdikian & Naghshineh, 2003). The difference in data formats further leads to the difficulty of incorporating multimedia objects within a unique indexing framework (Auffret et al., 1999).
- Last but not least, present research on content-based multimedia retrieval is based on features. These features are extracted from the audio/video streams or image pixels, with the empirical or heuristic selection, and then combined into vectors according to the application criteria (Hershey & Movellan, 1999). Due to the application-specific multimedia formats, this paradigm of multimedia data management lacks scalability, accuracy, efficiency and robustness (Westermann & Klas, 2003).

Representation: The Foundation of Multimedia Data Management

Successful storage and access of multimedia data, especially in a distributed heterogeneous database environment, require careful analysis of the following issues:

- Efficient representation of multimedia entities in databases
- Proper indexing architecture for the multimedia databases
- Proper and efficient technique to browse and/or query objects in multimedia database systems.

Among these three issues, multimedia representation provides the foundation for indexing, classification and query processing. The suitable representation of multimedia entities has significant impact on the efficiency of multimedia indexing and retrieval (Huang et al., 2003). For instance, object-level representation usually provides more convenient content-based indexing on multimedia data than pixel-level representation (Kim & Kim, 2002). Similarly, queries are resolved within the representation domains of multimedia data, either at the object level or pixel level (Hsu et al., 2000). The nearest-neighbor searching schemes are usually based on careful analysis of multimedia representation – the knowledge of data contents and organization in multimedia systems (Yu & Zhang, 2000; Li et al., 2003).

The remaining part of this article is organized into three sections: First, we offer the background and related work. Then, we introduce the concepts of semantic-based multimedia representation approach and compare it with the existing non-semantic-based approaches. Finally, we discuss the future trends in multimedia representation and draw this article into a conclusion.

BACKGROUND

Preliminaries of Multimedia Representation

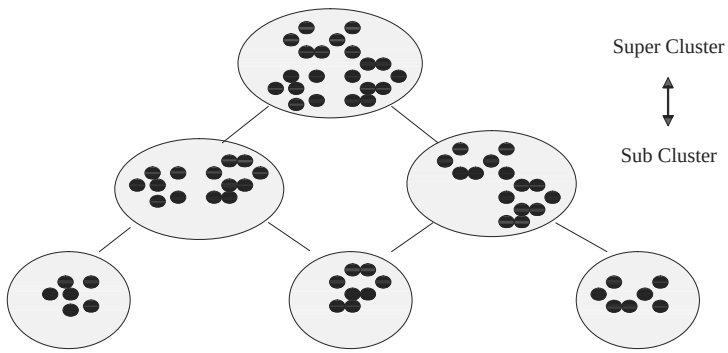
The main goal of multimedia representation is to obtain a concise content description during the analysis of multimedia objects. Representation approaches as advanced in the literature are classified into four groups: clustering-based, representative-region-based, decision-tree-based and annotation-based.

Clustering-Based Approach

The clustering-based approach recursively merges content-similar multimedia objects into clusters with human intervention or automated classification algorithms while obtaining the representation of these multimedia objects. There are two types of clustering schemes: *supervised* and *unsupervised* (Kim & Kim, 2002). The supervised clustering scheme utilizes the user's knowledge and input to cluster multimedia objects, so it is not a general-purpose approach. As expected, the unsupervised clustering scheme does not need interaction with the user. Hence, it is an ideal way to cluster unknown multimedia data automatically (Heisele & Ritter, 1999). Here we only discuss the unsupervised clustering scheme, because of its advantages.

In the clustering-based approach, the cluster of a multimedia object indicates its content (Rezaee, Zwet & Lelieveldt, 2000). The clusters are organized in a hierarchical fashion – a super cluster may be decomposed into several sub clusters and represented as the union of sub clusters (Figure 1). New characteristics are employed in the decomposition process to indicate the differences between sub clusters. Consequently, a sub cluster inherits the characteristics from its super cluster while maintaining its individual contents (Huang et al., 2003).

Figure 1. The decomposition of clusters



Representative-Region-Based Approach

The representative-region-based approach selects several representative regions from a multimedia object and constructs a simple description of this object based on the selected regions. The representative regions are some small areas with the most notable characteristics of the whole object. In case of an image, the representative regions can be areas that the color changes markedly, or areas that the texture varies greatly and so forth.

The representative-region-based approach is performed as a sequence of three steps:

- **Region selection:** The original multimedia object consists of many small regions. Hence, the selection of representative regions is the process of analyzing the changes in those small regions. The difference with the neighboring regions is quantified as a numerical value to represent a region. Finally, based on such a quantitative value, the regions are ordered, and the most notable regions are selected.
- **Function application:** The foundation of the function application process is the Expectation Maximization (EM) algorithm (Ko,& Byun, 2002). The EM algorithm is used to find the maximum likelihood function estimates when the multimedia object is represented by a small number of selected regions. The EM algorithm is divided into

two steps: E-step and M-step. In the E-step, the features for the unselected regions are estimated. In the M-step, the system computes the maximum-likelihood function estimates using the features obtained in the E-step. The two steps alternate until the functions are close enough to the original features in the unselected regions.

- **Content representation:** The content representation is the process that integrates the selected regions into a simple description that represents the content of the multimedia object. It should be noted that the simple description is not necessarily an exhaustive representation of the content. However, as reported in the literature, the overall accuracy of expressing multimedia contents is acceptable (Jing, Li, Zhang & Zhang, 2002).

Decision-Tree-Based Approach

The decision-tree-based approach is the process of obtaining content of multimedia objects through decision rules (MacArthur, Brodley & Shyu, 2000). The decision rules are automatically generated standards that indicate the relationship between multimedia features and content information. In the process of comparing the multimedia objects with decision rules, some tree structures – decision trees – are constructed (Simard, Saatchi & DeGrandi, 2000).

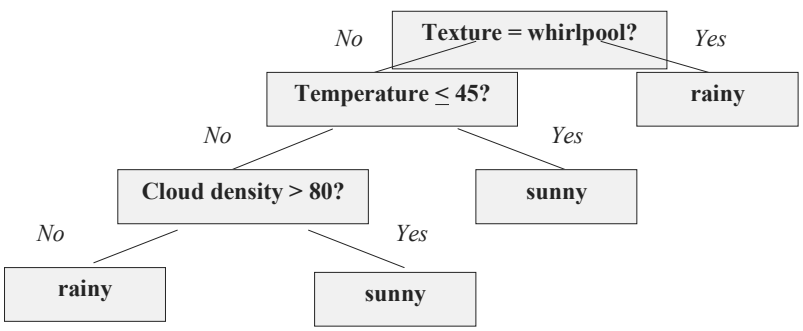
Table 1. The features of cloud images

Temperature	Cloud density	Texture	Weather
45	90	plain	rainy
50	60	whirlpool	rainy
65	75	plain	sunny
38	80	plain	rainy
77	50	plain	sunny
53	85	plain	rainy
67	100	whirlpool	rainy

The decision-tree-based approach is mostly applicable in application domains where decision rules can be used as standard facts to classify the multimedia objects (Park, 1999). For example, in a weather forecasting application, the satellite-cloud images are categorized as rainy and cloudy according to features such as cloud density and texture. Different combinations of feature values are related to different weathers (Table 1). A series of decision rules are derived to indicate these relationships (Figure 2). And the final conclusions are the contents of the multimedia objects.

The decision-tree-based approach can improve its accuracy and precision as the number of analyzed multimedia objects increases (Jeong & Nedevschi, 2003). Since the decision rules are obtained from statistical analysis of multimedia objects, more sample objects will result in improved accuracy (MacArthur et al., 2000).

Figure 2. A decision tree for predicting weathers from cloud images



Annotation-Based Approach

Annotation is the descriptive text attached to multimedia objects. Traditional multimedia database systems employ manual annotations to facilitate content-based retrieval (Benitez, 2002). Due to the explosive expansion of multimedia applications, it is both time-consuming and impractical to obtain accurate manual annotations for every multimedia object (Auffret et al., 1999). Hence, automated multimedia annotation is becoming a hotspot in recent research literature. However, even though humans can easily recognize the contents of multimedia data through browsing, building an automated system that generates annotations is very challenging. In a distributed heterogeneous environment, the heterogeneity of local databases introduces additional complexity to the goal of obtaining accurate annotations (Li et al., 2003).

Semantic analysis can be employed in annotation-based approach to obtain extended content description from multimedia annotations. For instance, an image containing "flowers" and "smiling faces" may be properly annotated as "happiness." In addition, a more complex concept may be deduced from the combination of several simpler annotations. For example, the combination of "boys," "playground" and "soccer" may express the concept "football game."

Comparison of Representation Approaches

The different rationales of these multimedia-representation approaches lead to their strengths and weaknesses in different application domains. Here these approaches are compared under the consideration of various performance merits (Table 2).

The approaches do not consider the semantic contents that may exist in the multimedia objects. Hence, they are collectively called "non-semantic-based" approaches. Due to the lack of semantic analysis, they usually have the following limitations:

- **Ambiguity:** The multimedia contents are represented as numbers that are not easily understood or modified.
- **Lack of robustness and scalability:** Each approach is suitable for some specific application domains, and achieves the best performance only when particular data

Table 2. Comparison of representation approaches

Performance Merit	Clustering	Representative Region	Decision Tree	Annotation
Rationale	Searching pixel-by-pixel, recognizing all details	Selecting representative regions	Treating annotations as multimedia contents	Using annotations as standard facts
Reliability & Accuracy	Reliable and accurate	Lack of robustness	Depending on the accuracy of annotations	Robust and self-learning
Time Complexity	Exhaustive, very time consuming	Most time is spent on region selection	Fast text processing	Time is spent on decision rules and feedback
Space Complexity	Large space requirement	Relatively small space requirement	Very small storage needed	Only need storage for decision rules
Application Domain	Suitable for all application domains	The objects that can be represented by regions	Need annotations as basis	Restricted to certain applications
Implementation Complexity	Easy to classify objects into clusters	Difficult to choose proper regions	Easily obtaining content from annotations	Difficult to obtain proper decision rules

formats are considered. None of them has the capability of accommodating multimedia data of any format from heterogeneous data sources.

MAIN FOCUS OF THE ARTICLE

The limitations of non-semantic-based approaches lead to the research on semantic-based multimedia-representation methods. One of the promising models in the literature is the summary-schemas model (SSM).

Summary Schemas Model

The SSM is a content-aware organization prototype that enables imprecise queries on distributed heterogeneous data sources (Ngamsuriyaroj, 2002). It provides a scalable content-aware indexing method based on the hierarchy of summary schemas, which comprises three major components: a thesaurus, a collection of autonomous local nodes and a set of summary-schemas nodes (Figure 3).

The thesaurus provides an automatic taxonomy that categorizes the standard accessing terms and defines their semantic relationships. A local node is a physical database containing the multimedia data. With the help of the thesaurus, the data items in local databases are classified into proper categories and represented with abstract and semantically equivalent summaries. A summary-schemas node is a virtual entity concisely describing the semantic contents of its child/children node(s). More detailed descriptions can be found in Jiao and Hurson (2004).

To represent the contents of multimedia objects in a computer-friendly structural fashion, the SSM organizes multimedia objects into layers according to their semantic contents. A multimedia object – say, an image – can be considered as the combination of a set of elementary entities, such as animals, vehicles and buildings. And each elementary entity can be described using some logic predicates that indicate the mapping of the elementary entity on different features. For instance, the visual elementary objects in Figure 4 are dog and cat. The possible color is grey, white, blue or brown. The texture pattern is $texture_1$, $texture_2$ or $texture_3$. Hence, the example image in Figure 4 can be represented as the combination of visual objects, colors and textures, such as (cat $\wedge$ brown $\wedge$ t3) $\vee$ (dog $\wedge$ grey $\wedge$ t1).

Figure 3. Summary Schemas Model

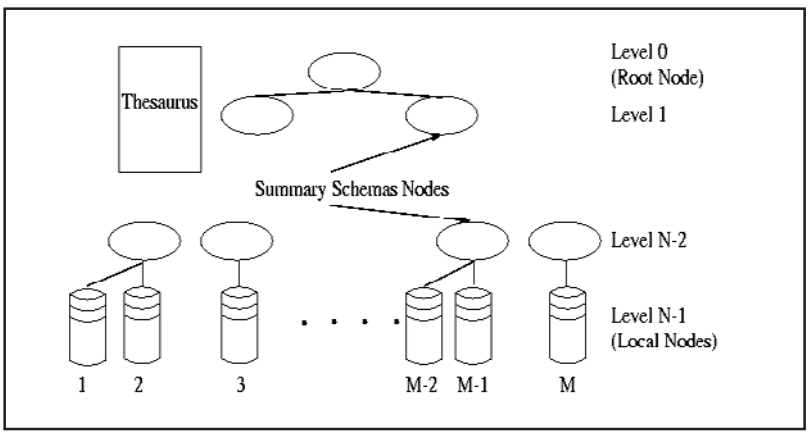


Figure 4. Semantic content components of image objects

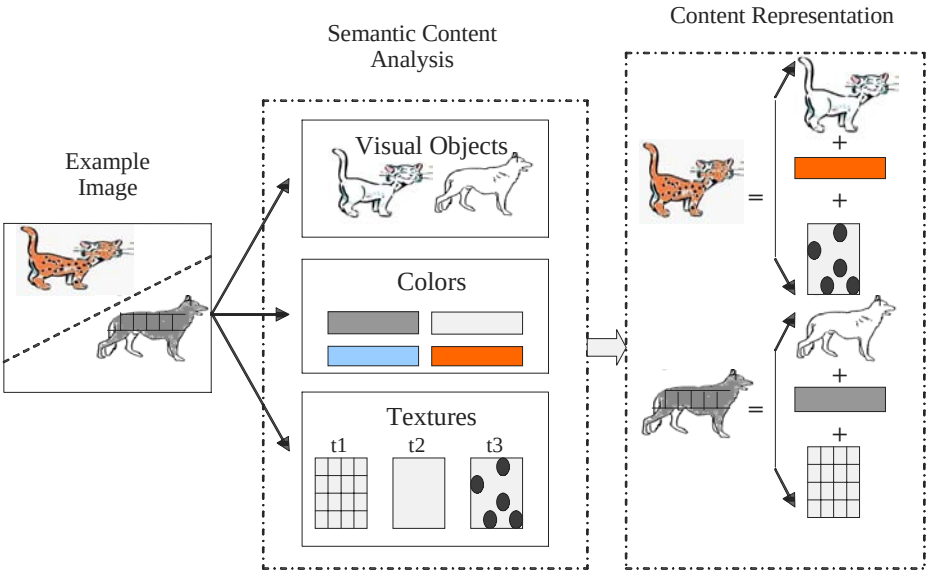
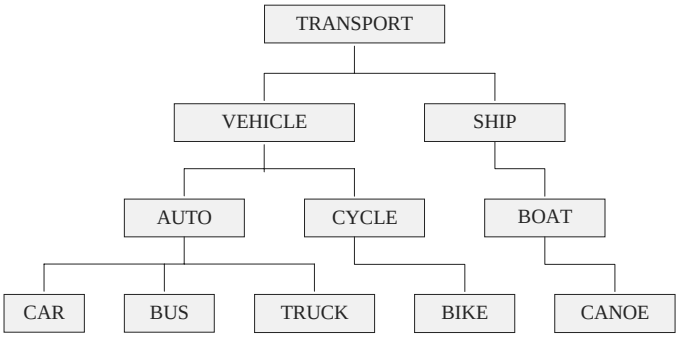


Non-Semantic-Based Methods vs. Semantic-Based Scheme

In contrast with the multimedia-representation approaches mentioned earlier, the SSM employs a unique semantic-based scheme to facilitate multimedia representation and organization. A multimedia object is considered as a combination of logic terms that represents its semantic content. The analysis of multimedia contents is then converted to the evaluation of logic terms and their combinations. This content-representation approach has the following advantages:

- The semantic-based descriptions provide a convenient way of representing multimedia contents precisely and concisely. Easy and consistent representation of the elementary objects based on their semantic features simplifies the content representation of complex objects using logic computations – the logic representation of multimedia contents is often more concise than feature vector, which is widely used in non-semantic-based approaches.
- Compared with non-semantic-based representation, the semantic-based scheme integrates multimedia data of various formats into a unified logical format. This also allows the SSM to organize multimedia objects regardless of their representation (data formats such as MPEG) uniformly, according to their contents. In addition, different media types (video, audio, image and text) can be integrated under the SSM umbrella, regardless of their physical differences.
- The semantic-based logic representation provides a mathematical foundation for operations such as similarity comparison and optimization. Based on the equivalence of logic terms, the semantically similar objects can be easily found and grouped into same clusters to facilitate data retrieval. In addition, mathematical techniques can be used to optimize the semantic-based logic representation of multimedia entities – this by default could result in better performance and space utilization.
- The semantic-based representation scheme allows one to organize multimedia objects

Figure 5. The SSM hierarchy for multimedia objects



in a hierarchical fashion based on the SSM infrastructure (Figure 5). The lowest level of the SSM hierarchy comprises multimedia objects, while the higher levels consist of summary schemas that abstractly describe the semantic contents of multimedia objects. Due to the descriptive capability of summary schemas, this semantic-based method normally achieves more representation accuracy than non-semantic-based approaches.

FUTURE TRENDS AND CONCLUSION

The literature has reported considerable research on multimedia technologies. One of the fundamental research areas is the content representation of multimedia objects. Various non-semantic-based multimedia-representation approaches have been proposed in the literature, such as clustering-based approach, representative-region-based approach, decision-tree-based approach and annotation-based approach. Recent research results also show some burgeoning trends in multimedia-content representation:

- Multimedia-content processing through cross-modal association (Westermann,& Klas, 2003; Li et al., 2003).
- Content representation under the consideration of security (Adelsbach et al., 2003; Lin & Chang, 2001).
- Wireless environment and its impact on multimedia representation (Bourgeois et al., 2003; Kwon et al., 2003).

This article briefly overviewed the concepts of multimedia representation and introduced a novel semantic-based representation scheme – SSM. As multimedia applications keep proliferating through the Internet, the research on content representation will become more and more important.

KEY TERMS

Annotation: Descriptive text attached to multimedia objects.

Cluster: A group of content-similar multimedia objects.

Decision Rule: Automatically generated standards that indicate the relationship between multimedia features and content information.

Elementary Entity: Data entities that semantically represent basic objects.

Representative Region: Areas with the most notable characteristics of a multimedia object.

Semantic-Based Representation: Describing multimedia content using semantic terms.

Summary-Schemas Model: A content-aware organization prototype that enables imprecise queries on distributed heterogeneous data sources.

This work was previously published in Encyclopedia of Multimedia Technology and Networking, edited by M. Pagani, pp. 687-695, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 3.2
Multimedia for Mobile Devices

Kevin Curran
University of Ulster, Ireland

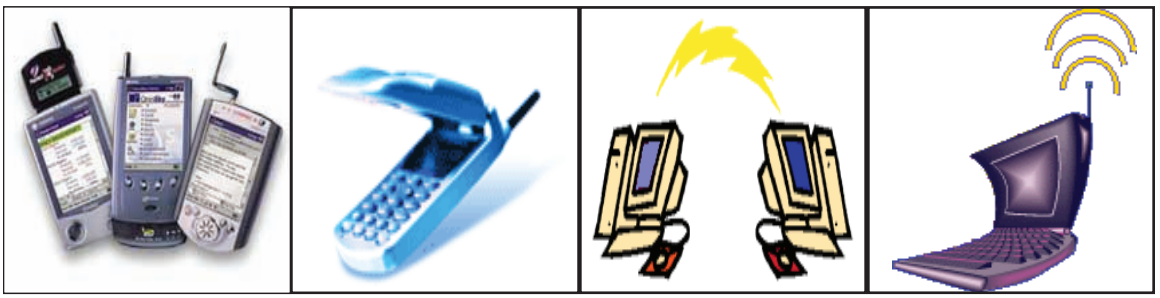
INTRODUCTION

Mobile communications is a continually growing sector in industry and a wide variety of visual services such as video-on-demand have been created, which are limited by low-bandwidth network infrastructures. The distinction between mobile phones and personal device assistants (PDA's) has already become blurred with pervasive computing being the term coined to describe the tendency to integrate computing and communication into everyday life. New technologies for connecting devices like wireless communication and high bandwidth networks make the network connections even more heterogeneous. Additionally, the network topology is no longer static, due to the increasing mobility of users. Ubiquitous computing is a term often associated with this type of networking.

BACKGROUND

The creation of low bit rate standards such as H.263 (Harrysson, 2002) allows reasonable quality video through the existing Internet and is an important step in paving the way forward. As these new media services become available, the demand for multimedia through mobile devices will invariably increase. Corporations such as Intel do not plan to be left behind. Intel has created a new breed of mobile chip code named Banias. Intel's president and chief operating officer Paul Otellino states that "eventually every single chip that Intel produces will contain a radio transmitter that handles wireless protocols, which will allow users to move seamlessly among networks. Among our employees this initiative is affectionately referred to as 'radio free Intel.'" Products such as Real Audio and IPCast for streaming media are also becoming increasingly common, however, multimedia, due to its timely nature requires guarantees different in nature with regards to delivery of data from TCP traffic such as HTTP requests. In addition, multimedia applications increase the set of requirements in terms of throughput, end-to-end delay, delay jitter, and clock synchronisation. These requirements may not all be directly met by the networks therefore end-system protocols enrich network services

Figure 1. (a) PDAs; (b) mobiles; (c) desktops; (d) laptops



(a) (b) (c) (d)

to provide the quality of service (QoS) required by applications. It is argued here that traditional monolithic protocols are unable to support the wide range of application requirements on top of current networks (ranging from 9600 baud modems up to gigabit networks) without adding overhead in the form of redundant functionality for numerous combinations of application requirements and network infrastructures. In ubiquitous computing, software is used by roaming users interacting with the electronic world through a collection of devices ranging from handhelds such as PDAs (Figure 1a) and mobile phones (Figure 1b) to personal computers (Figure 1c) and laptops (Figure 1d).

The Java language, thanks to its portability and support for code mobility, is seen as the best candidate for such settings (Kochnev & Terekhov, 2003; Román et al., 2002). The heterogeneity added by modern smart devices is also characterised by an additional property, which is that many of these devices are typically tailored to distinct purposes. Therefore, not only memory and storage capabilities differ widely, but local device capabilities, in addition to the availability of resources changing over time (e.g., a global positioning satellite (GPS) system cannot work indoors unless one uses specialised repeaters (Jee, Boo, Choi, & Kim, 2003). Therefore a need exists for middleware to be aware of these pervasive computing properties. With regards to multimedia, applications that use group communication (e.g., video conferencing) mechanisms must be able to scale from small groups with few members, up to groups with thousands of receivers (Tojo, Enokido, & Takizawa, 2003).

The protocols underlying the Internet were not designed for the latest cellular type networks with their low bandwidth, high error losses, and roaming users, thus many "fixes" have arisen to solve the problem of efficient data delivery to mobile resource constrained devices (Saber & Mirenkov, 2003). Mobility requires adaptability meaning that systems must be location-aware and situation-aware taking advantage of this information in order to dynamically reconfigure in a distributed fashion (Matthur & Mundur, 2003; Solon, McKevitt, & Curran, 2003). However, situations, in which a user moves an end-device and uses information services can be challenging. In these situations, the placement of different cooperating parts is a research challenge.

ENABLING TECHNOLOGIES FOR MOBILE MULTIMEDIA

In 1946, the first car-based telephone was set up in St. Louis, MO, USA. The system used a single radio transmitter on top of a tall building. A single channel was used, and therefore a button was pushed to talk and released to listen (Tanenbaum, 2005). This half duplex system is still used by modern day CB-radio systems used by police and taxi operators. In the 60's, the system was improved to a two-channel system called improved mobile

telephone system (IMTS). The system could not support many users as frequencies were limited. The problem was solved by the idea of using cells to facilitate the re-use of frequencies. More users can be supported in such a cellular radio system. It was implemented for the first time in the advanced mobile phone system (AMPS). Wide-area wireless data services have been more of a promise than a reality. It can be argued that success for wireless data depends on the development of a digital communications architecture that integrates and interoperates across regional-area, wide-area, metropolitan-area, campus-area, in-building, and in-room wireless networks.

The convergence of two technological developments has made mobile computing a reality. In the last few years, the UK and other developed countries have spent large amounts of money to install and deploy wireless communication facilities. Originally aimed at telephone services (which still account for the majority of usage), the same infrastructure is increasingly used to transfer data. The second development is the continuing reduction in the size of computer hardware, leading to portable computation devices such as laptops, palmtops, or functionally enhanced cell phones. Unlike second-generation cellular networks, future cellular systems will cover an area with a variety of non-homogeneous cells that may overlap. This allows the network operators to tune the system layout to subscriber density and subscribed services. Cells of different sizes will offer widely varying bandwidths: very high bandwidths with low error rates in pico-cells, very low bandwidths with higher error rates in macro-cells as illustrated in Table 1. Again, depending on the current location, the sets of available services might also differ.

Unlike traditional computer systems characterised by short-lived connections that are bursty in nature, Streaming audio/video sessions are typically long lived (the length of a presentation) and require continuous transfer of data. Streaming services will require, by today's standards, the delivery of enormous volumes of data to customer homes. For examples, entertainment NTSC video compressed using the MPEG standards requires bandwidths between 1.5 and 6 Mb/s. Many signalling schemes have been developed that can deliver data at this rate to homes over existing communications links (Forouzan, 2002). Some signalling schemes suitable for high-speed video delivery are:

- **ADSL:** The asymmetrical digital subscriber loop (ADSL) (Bingham, 2000) takes advantage of the advances in coding to provide a customer with a downstream wideband signal, an upstream control. The cost to the end-user is quite low in this scheme, as it requires little change to the existing equipment.

Table 1. Characteristics of various wireless networks

Type of Network	Bandwidth Latency	Latency	Mobility	Typical Video Performance	Typical Audio Performance
In-Room/Building (Radio Frequency Infrared)	>> 1 Mbps RF: 2-20 Mbps IR: 1-50 Mbps	<< 10 ms	Pedestrian	2-Way, Interactive, Full Frame Rate (Compressed)	High Quality, 16 bit samples, 22 KHz rate
Campus-Area Packet Relay	Approx. 64 kbps	Approx. 100 ms	Pedestrian	Medium Quality Slow Scan	Medium Quality Reduced Rate
Wide-Area (Cellular, PCS)	19.2 kbps	> 100 ms	Pedestrian/ Vehicular	Video Phone or Freeze Frame	Asynchronous "Voice Mail"
Regional-Area (LEO/VSAT DBS)	Asymmetric Up/Dn 100 bps to 4.8 kbps 12 Mbps	>> 100 ms	Pedestrian/ Vehicular Stationary	Async Video Playback	Asynchronous "Voice Mail"

- **CATV:** Cable TV (CATV) (Forouzan, 2002) uses a broadband coaxial cable system and can support multiple MPEG compressed video streams. CATV has enormous bandwidth capability and can support hundreds of simultaneous connections. Furthermore, as cable is quite widely deployed, the cost of supporting Video-on-demand and other services is significantly lower. However, it requires adaptation to allow bi-directional signalling in the support of interactive services.

A cellular wireless network consists of fixed based stations connecting mobile devices through a wired backbone network where each mobile device establishes contact through their local base stations. The available bandwidth on a wireless link is limited and channels are more prone to errors. It is argued that future evolution of network services will be driven by the ability of network elements to provide enhanced multimedia services to any client anywhere (Harrysson, 2002). Future network elements must be capable of transparently accommodating and adjusting to client and content heterogeneity. There are benefits to filtering IP packets in the wireless network so that minimal application data is carried to the mobile hosts to preserve radio resources and prevent the overloading of mobile hosts with unnecessary information and ultimately wasteful processing. A proxy is an intermediary component between a source and a sink, which transforms the data in some manner. In the case of mobile hosts, a proxy is often an application that executes in the wired network to support the host. This location is frequently the base station, the machine in the wired network that provides the radio interface. As the user moves, the proxy may also move to remain on the communication path from the mobile device to the fixed network. The proxy hides the mobile from the server, which thinks that it communicates with a standard client (i.e., a PC directly connected to the wired network) (Kammann & Blachnitzky, 2002).

Wireless links are characterised by relatively low bandwidth and high transmission error rates (Chakravorty & Pratt, 2002). Furthermore, mobile devices often have computational constraints that preclude the use of standard Internet video formats on them thus by placing a mobile transcoding proxy at the base station (BS), the incoming video stream can be transcoded to a lower bandwidth stream, perhaps to a format more suitable to the nature of the device, and control the rate of output transmission over the wireless link (Joshi, 2000).

Figure 2 illustrates a scenario where a transcoding gateway is configured to transcode MPEG streams to H.261. In the architecture, the transcoding gateway may also simply forward MPEG or H.261 packets to an alternate session (in both directions) without performing transcoding. Figure 3 illustrates locations in which intelligence about available network services may be placed. Client may utilise this network knowledge to select the most appropriate server and mechanism in order to obtain appropriate content. As an alternative, this knowledge (and the associated burden) could be entirely or partially transferred to the individual servers or could reside inside the network.

Image transcoding is where an image is converted from one format to another (Vetro, Sun,

Figure 2. A transcoding proxy

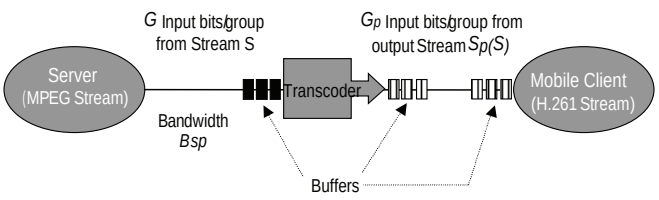


Figure 3. Variations in client-server connectivity

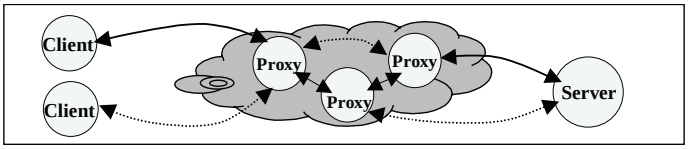

& Wang, 2001). This may be performed by altering the Qscale (basically applying compression to reduce quality). This is sometimes known as simply resolution reduction. Another method is to scale down the dimensions of the image (spatial transcoding) (Chandra, Gehani, Schlatter Ellis, & Vahdat, 2001) so reduce the overall byte size (e.g., scaling a 160Kb frame by 50% to 32KB). Another method known as temporal transcoding is where frames are simply dropped (this can sometimes be known as simply rate reduction). While another method may be simply to transcode the image to greyscale, which may be useful for monochrome PDA,'s (again this transcoding process results in reduced byte size of the image or video frame). Recently there has been increased research into intelligent intermediaries). Support for streaming media in the form of media filters has also been proposed for programmable heterogeneous networking. Canfora, Di Santo, Venturi, Zimeo, and Zito (2005) propose multiple proxy caches serving as intelligent intermediaries, improving content delivery performance by caching content. A key feature of these proxies is that they can be moved and re-configured to exploit geographic locality and content access patterns thus reducing network server load. Proxies may also perform content translation on static multimedia in addition to distillation functions in order to support content and client heterogeneity (Yu, Katz, & Laksham, 2005). Another example is fast forward networks broadcast overlay architecture where there are media bridges in the network, which can be used in combination with RealAudio or other multimedia streams to provide an application layer multicast overlay network. One could adopt the view at this time that "boxes" are being placed in the network to aid applications.

MOBILE IP

Mobile IP is an extension to IP, which allows the transparent routing of IP datagrams to mobile nodes. In mobile IP, each host has a home agent (i.e., a host connected to the sub network the host is attached to). The home agent holds responsibility for tracking the current point of attachment of the mobile device so when the device changes the network it is connected to it has to register a new care-of address with the home agent. The care-of address can be the address of a foreign agent (e.g., a wireless base station node) that has agreed to provide services for the mobile or the new IP address of the mobile (if one is dynamically assigned by its new network). Traffic to mobiles is always delivered via home agents, and then tunnelled to the care-of address. In the case of a foreign agent care-of address, traffic is forwarded to the mobile via the foreign agent. Traffic from the mobile does not need to travel via the home agent but can be sent directly to (previously) correspondents. Correspondent hosts do not need to be mobile IP enabled or even have to know the location of the mobile if a home agent acts as an intermediary, thus forwarding of packets to the current address of the mobile is transparent for other hosts [Dixit02]. The home agent redirects packets from the home network to the care-of address by creating a new IP header, which contains the mobile's care-of address as the destination IP address. This new header encapsulates the

original packet, causing the mobile node's home address to have no effect on the encapsulated packet's routing until it reaches the care-of address. When the mobile leaves the service area of its current foreign agent and registers with a new foreign agent, the home agent must be informed about the change of address. In the process of handoff, the mobile may lose connectivity for a short period of time.

FUTURE TRENDS

Mobile phone technologies have evolved in several major phases denoted by "generations" or "G" for short. Three generations of mobile phones have evolved so far, each successive generation more reliable and flexible than the previous. The first of these is referred to as the first generation or 1G. This generation was developed during the 1980s and early 1990s and only provided an analog voice service with no data services available (Bates, 2002). The second generation or 2G of mobile technologies used circuit-based digital networks. Since 2G networks are digital they are capable of carrying data transmissions, with an average speed o f around 9.6K bps (bits per second). Because 2G networks can support the transfer of data, they are able to support Java enabled phones. Some manufacturers are providing Java 2 Micro Edition (J2ME) (Knudsen & Li, 2005) phones for 2G networks though the majority are designing their Java enabled phones for the 2.5G and 3G networks, where the increased bandwidth and data transmission speed will make these applications more usable (Hoffman, 2002). These are packet based and allow for "always on" connectivity. The third generation of mobile communications (3G) is digital mobile multimedia offering broadband mobile communications with voice, video, graphics, audio and other forms of information. 3G builds upon the knowledge and experience derived from the preceding generations of mobile communication, namely 2G and 2.5G although 3G networks use different transmission frequencies from these previous generations and therefore require a different infrastructure (Camarillo& Garcia-Martin, 2005). These networks will improve data transmission speed up to 144K bps in a high-speed moving environment, 384K bps in a low-speed moving environment, and 2Mbps in a stationary environment. 3G services see the logical convergence of two of the biggest technology trends of recent times, the Internet and mobile telephony. Some of the services that will be enabled by the broadband bandwidth of the 3G networks include:

- Downloadable and streaming audio and video
- Voice over Internet protocol (VoIP)
- Send and receive high quality colour images
- Electronic agents are self-contained programs that roam communications networks delivering /receiving messages or looking for information or services.
- Downloadable software—Potential to be more convenient than conventional methods of distributing software as the product arrives in minutes
- Capability to determine geographic position of a mobile device using the global positioning system (GPS) (Barnes et al., 2003)

3G will also facilitate many other new services that have not previously been available over mobile networks due to the limitations in data transmission speeds. These new wireless applications will provide solutions to companies with distributed workforces, where employees need access to a wide range of information and services via their corporate intranets, when they are working offsite with no access to a desktop (Camarillo & Camarillo, 2005).

4G technology stands to be the future standard of wireless devices. The Japanese company NTT DoCoMo is testing 4G communication at

100 Mbit/s while moving, and 1 Gbit/s while stationary. NTT DoCoMo plans on releasing the first commercial network in 2010. Despite the fact that current wireless devices seldom utilize full 3G capabilities, there is a basic attitude that if you provide the pipeline then services for it will follow.

CONCLUSION

Flexible and adaptive frameworks are necessary in order to develop distributed multimedia applications in such heterogeneous end-systems and network environments. The processing capability differs substantially for many of these devices with PDA's being severely resource constrained in comparison to leading desktop computers. The networks connecting these devices and machines range from GSM, Ethernet LAN, and Ethernet 802.11 to Gigabit Ethernet. Networking has been examined at a low-level micro-protocol level and again from a high-level middleware framework viewpoint. Transcoding proxies were introduced as a promising way to achieving dynamic configuration, especially because of the resulting openness, which enables the programmer to customize the structure of the system and other issues regarding mobility were also discussed.

KEY TERMS

Bandwidth: The amount of data that can be transferred from one point to another, usually between a Web server and a Web browser; It is a measure of the range of frequencies a transmitted signal occupies. In digital systems, bandwidth is the data speed in bits per second. In analog systems, bandwidth is measured in terms of the difference between the highest-frequency signal component and the lowest-frequency signal component.

Broadband: The telecommunication that provides multiple channels of data over a single communications medium.

Cellular Network: A cellular wireless network consists of fixed based stations connecting mobile devices through a wired backbone network where each mobile device establishes contact through their local base stations. The available bandwidth on a wireless link is limited and channels are more prone to errors.

Content: Data that an encoder or server streams to a client or clients. Content can originate from live audio or live video presentation, stored audio or video files, still images, or slide shows. The content must be translated from its original state into a Windows Media format before a Windows Media server can stream it. Windows Media servers can stream live streams or stored Window Media files as content.

Encoding: Encoding accomplishes two main objectives: (1) it reduces the size of video and audio files, by means of compression, making Internet delivery feasible, and (2) it saves files in a format that can be read and played back on the desktops of the targeted audience. Encoding may be handled by a software application or by specialised hardware with encoding software built in.

Media: A term with many different meanings, in the context of *streaming media*, it refers to video, animation, and audio. The term "media" may also refer to something used for storage or transmission, such as tapes, diskettes, CD-ROMs, DVDs, or networks such as the Internet.

Multiple Bit Rate Video: The support of multiple encoded video streams within one media stream. By using multiple bit rate video in an encoder, you can create media-based content that has a variety of video streams at variable bandwidths ranging from, for example, 28.8 Kbps through 300 Kbps, as well as a separate audio stream. After receiving this multiple encoded stream, the server determines which bandwidth to stream based on the network bandwidth available. Multiple bit rate video is not supported on generic HTTP servers.

Streaming Video: A sequence of moving images that are transmitted in compressed form over the Internet and displayed by a viewer as they arrive; is usually sent from pre-recorded video files, but can be distributed as part of a live broadcast feed.

Third Generation Mobile Communications (3G): The third generation of mobile communications (3G) is digital mobile multimedia offering broadband mobile communications with voice, video, graphics, audio, and other forms of information.

Web Casting: The technique of broadcasting media over an intranet, extranet, or the Internet.

Web Server Streaming: Another term for HTTP streaming, pseudo-streaming, or progressive download

INTRODUCTION

Electronic mobile devices are becoming more and more powerful in terms of memory size, computational speed, and color display quality. These devices can now perform many multimedia functions, including rendering text, sound, images, color graphics, video, and animation. They can provide users with great entertainment values, which were only possible with more expensive and bulky equipment before.

Technological advances in computer and telecommunications networks have also made mobile devices more useful for information exchange among users. As a result, a number of new mobile products and services, such as multimedia messages services (MMSs) and online games, can be offered to users by the industry.

It is commonly believed that "contents are the king" for multimedia products and services. As the mobile handsets and networks become more and more advanced, there is a stronger and stronger demand for high-quality multimedia contents to be used in new hardware systems. Content creation involves both computer technology and artistic creativity. Due to a large number of users, mobile entertainment has become an important part of the so-called creative industry that is booming in many countries.

In this article, we provide an overview of multimedia contents for mobile entertainment applications. The objective is for the readers to become familiar with basic multimedia technology, and the concepts and commonly used terms. Our focus will be on multimedia signal representation, processing, and standards.

SOUND

The original sound, such as speech from humans, can be represented as a continuous function $s(t)$. The sound can be recorded using electronic devices and stored on magnetic tapes. It can also be transmitted through telecommunications systems. The traditional telephone is used to send and receive waveform information of sound signals. The function $s(t)$ here is called an analog audio signal. This signal can be sampled every T seconds, or $f_s = 1/T$ times per second. The output signal is called a discrete-time signal. Each data sample in a discrete-time signal can have an arbitrary value. The sample values can be quantized so that we can represent them using a limited number of bits in the computer. These two processes, sampling and quantization, are called digitization, which can be achieved using an analog-to-digital converter (ADC) (Chapman & Chapman, 2004; Gonzalez & Woods, 2002; Mandal, 2003; Ohm, 2004). A signal $s(n)$ that is discrete both in time and in amplitude is called a digital signal. To render a digital sound signal, we must use a digital-to-analog converter (DAC) and send the analog signal to an electronic speaker.

The parameter $f_s = 1/T$ is called the sampling frequency. For telephone applications, usually f_s = 8000Hz, and for audio CD usually f_s = 44100Hz. To achieve stereo effects, the audio CD has two channels of data. There is only one channel in telephone applications. The sampling frequency f_s must be greater or equal to twice the signal bandwidth in order to reconstruct or recover the analog signal correctly. This is called the Nyquist sampling criterion. In telephone systems, a sound signal may have to be filtered to remove high-frequency components so that the sampling criterion is satisfied. This is why audio CDs have a higher sound quality than telephones.

The sound information can be stored as raw digital data. Some sound files, such as WAVE files (with extension ".wav") used on PCs, store raw sound data. This kind of format requires large storage space but has the advantage, since there is no information loss and the data can be accessed easily and quickly. To reduce the amount of data for storage and transmission, sound data are often compressed. Commonly used sound data compression methods include the m-law transformation, adaptive differential pulse code modulation (ADPCM), and Moving Picture Experts Group (MPEG) audio compression (Chapman & Chapman, 2004; Mandal, 2003; MPEG, n.d.; Ohm 2004).

Currently, MPEG Audio Layer 3 (MP3) is a very popular sound data compression technique for mobile devices. MP3 is also a well-known sound file format. During data compression in MP3, a sound signal is decomposed into 32 frequency bands, and psychoacoustic models are used to determine the masking level and bit allocation pattern for each band. Modified discrete cosine transform (MDCT) is used to compress the data. The discrete cosine transform (DCT) has the so-called energy compact property—that is, it is able to pack most of the energy of a signal in a small number of DCT coefficients. For example, if $s(0) = 2$, $s(1) = 5$, $s(2) = 7$, and $s(3) = 6$, then the DCT coefficients are $S(0) = 10$, $S(1) = 3.15$, $S(2) = 2$, and $S(3) = 0.22$ (Mandal, 2003). In this case, from $S(0)$ to $S(3)$, the coefficients become smaller and smaller. We can simply retain the low-frequency components $S(0)$ and $S(1)$ and discard high-frequency ones $S(2)$ and $S(3)$ to obtain an approximation of the original signal. In practice, we can allocate more bits to code $S(0)$ and less and less bits for $S(1)$ to $S(3)$ to achieve a high compression ratio and at the same time maintain good signal quality.

Short sound files can be completely downloaded to mobile devices before being played. To reduce waiting time for downloading long sound files, audio streaming technology can be used (Austerberry 2005). In a streaming system, audio data is transmitted through a network and played by a mobile device as the data become available. That is, a sound does not have to be completely

stored in the mobile device before being played. Steaming is useful if a large amount of data need to be received by a mobile device or live broadcasting is required.

We have focused on how to process sound waveform information above. In fact, sound can also be generated according to its parameters or a set of instructions. The musical instrument digital interface (MIDI) standard is used for such purpose (Chapman & Chapman, 2004; Mandal, 2003). A MIDI file contains information on what kind of instruments, such as different types of pianos, should be used and how they should be played. Several instruments can be arranged in different channels and played at the same time. MIDI files are much smaller than waveform-based sound files for music and is widely used for ring tones on mobile phones.

IMAGES

The imaging ability of mobile devices has been improved rapidly in recent years. Now most new mobile phones are equipped with digital cameras and can take pictures with millions of pixels. Software programs are available to edit an image, such as to enhance its contrast and change its color appearance. Mobile devices can also be used to send or receive images and browse the Web.

An important parameter for images is the resolution, which is closely related but should not be confused with the image size. Image resolution is usually measured by dots per inch (dpi). Higher resolution for the same physical area of an object would generate a larger image than lower resolution, but a large image does not necessarily mean a high resolution as it depends on the area that the image covers. The concept of resolution is often used in image printing and scanning. Typically, laser printers have a resolution of 300dpi or 600dpi and fax documents have resolutions from 100dpi to 300dpi.

A digital image can be considered as a two-dimensional (2D) discrete function $i(x, y)$. Like sound data, images need to be compressed to save storage space and transmission time. There are a number of methods that can be used to compress an image. Most methods are designed to reduce the spatial redundancy so that an image can be represented using a smaller amount of data. The most popular technique used for image compression is the Joint Photographic Experts Group (JPEG) standard (Gonzalez & Woods 2002). In JPEG-based compression, an image is divided into small, square blocks, and each block is transformed using the two-dimensional DCT (2D-DCT). Similar to audio data compression, the energy of a smooth image is concentrated in low-frequency components of the 2D-DCT coefficients. By allocating more bits to a small number of low-frequency components than to a large number of high-frequency components, we can achieve effective data compression.

In the JPEG2000 standard, the 2D discrete wavelet transform (2D-DWT) is used for image compression. In this method, an image is decomposed into several sub-bands, and different quantization schemes are used for different sub-bands. The 2D-DWT usually performs better—that is, it can provide a higher quality for similar compression ratio or a higher compression ratio for similar image quality than the 2D-DCT.

The JPEG and JPEG200 standards are usually used to provide lossy compression with a high compression ratio, although they can also be used for lossless compression. In lossy compression, the decompressed image is only an approximation of the original one, and as a result the image may appear to be blocky and blurred. The quality of an image from lossy compression can be improved using a number of techniques (Liew & Yan, 2004; Weerasingher, Liew, & Yan, 2002; Zou & Yan, 2005). In lossless compression, we can reconstruct or recover the original image exactly. Commonly used lossless compression methods include graphic interchange format (GIF), tagged

image file format (TIFF), and portable network graphics (PNG). A GIF image can only show 256 colors and is especially useful for logos, buttons, borders, and simple animation on Web pages. GIF is a patented technology. In TIFF, image information is associated with different tags, which can be defined by users. TIFF is widely used for scanned office documents. PNG, which can support true colors, has been developed to be a royalty-free alternative to GIF. Similar to GIF, PNG can provide background transparency, but PNG does not support animation.

GRAPHICS

An image can also be generated from a set of drawing operations, similar to the way music is generated from MIDI instructions. Images represented by pixel values are called bitmaps, while those obtained from drawings are called vector graphics. The bitmap format is better for natural objects, such as human faces and outside sceneries, whereas the vector format is better for computer-generated objects, such as line drawings and industrial designs.

On computers and mobile devices, different operating or window systems provide different graphics utilities as software development tools. In general, they should all have graphics functions for drawing line shapes, such as lines, polygons, and circles, and displaying bitmaps. Some systems provide more advanced functions, such as geometric shape transformations, color gradients, and spline curve and surface displays. Currently, there are many proprietary mobile operating systems developed by different manufacturers. This makes it difficult to port graphics applications from one phone model to another model. However, a few systems have been adopted by more and more manufacturers. They include Symbian, Microsoft Windows Mobile OS, and Linux-based mobile OS.

There are also several graphics formats that are supported by many mobile operating systems. They include proprietary formats Java 2 Micro Edition (J2ME) and Flash, and royalty-free and open standard scalable vector graphics (SVG). J2ME is a general purpose programming language for small electronic devices and contains many useful graphics functions (Edward, 2003; Wells, 2004). It has gained widespread use in mobile phones, especially for games.

Flash was developed by Macromedia, which is now part of Adobe Systems. In addition to graphics, Flash can also be used to present other types of multimedia data, such as text, sound, and animation. The output file of Flash is called an SWF movie, which contains definition tags and control tags. The definition tags describe the objects in a movie, such as text, shapes, bitmaps, sound, and sprites. The control tags define how and when an object should be transformed and displayed. SWF movie files use a very compact binary format, so they can be transmitted over the Internet quickly. They have found many applications to Web page design and are now used more and more in mobile phones. Macromedia Flash provides an authoring tool to design SWF movies. One can also create a SWF movie using a computer program according to the SWF file format.

SVG is an open graphics standard developed by the World Wide Web Consortium (W3C). It is royalty free and vendor independent. SVG uses text format and provides a language to define graphics display, in a way similar to the HyperText Markup Language (HTML) that defines text display. SVG can be used to describe vector shapes, text, bitmap images, and animation. Since vector graphics can be easily scaled larger or smaller, SVG files can be used for different resolutions, such as in printing which requires a high resolution, and in displays on mobile devices which have low resolution. A number of graphics software packages, such as CorelDraw and Adobe Illustrator, can output SVG files.

VIDEO

A digital video contains a sequence of images $v(x, y, n)$, where x and y are spatial coordinates and n represents time. For each n value or a time sample, we have a frame of video or an image. In video compression, we can explore both spatial or intra-frame redundancy and temporal or inter-frame redundancy. Spatially, a frame can be compressed just like an image. Temporally, a frame is similar to its proceeding frame, so we can expect a higher compression ratio for video than for each image separately and independently.

A straightforward way of reducing the temporal redundancy is to use the proceeding frame and approximation of the current frame. A better approximation can be achieved if we take into account movements of the objects in the image sequence. We can divide an image into small blocks and search in the proceeding frame for a closest shifted version of each block. Then, we only need to code the difference between the block under consideration and its closest match in the previous frame, and the shift between the two blocks. This procedure is called motion estimation.

Extensive research has been carried out in the field of video processing on how to estimate and compensate motions efficiently.

A series of MPEG standards have been developed for video compression (MPEG, n.d.; Watkinson, 2004). MPEG-1 was developed for coding of moving pictures and associated audio for digital storage media, such as video CD and MP3, at up to 1.5 Mbit/s. It uses block motion compensation and the DCT to code the residual image. MPEG-2 provides generic coding of moving pictures and associated audio information for bit rates from 1.5 to 80 Mbit/s. It is an extension of MPEG-1, allows combinations of video and audio streams, and supports different packet formats for data transmission. MPEG-2 products include digital TV setup boxes and DVDs. MPEG-4 provides standardized technology for video and audio data storage, transmission, and content access and manipulation on digital TV, interactive graphics applications, and the World Wide Web. In addition to video and audio coding, it supports creation of synthetic objects. For example, mesh models can be used for human face animation. MPEG-7 is a standard for describing multimedia content, including images, graphics, 3D models, audio, speech, video, and the way various data should be combined in a multimedia presentation. MPEG-21, which is still under development, defines the multimedia framework for different users, including content creators, producers, distributors, and service providers, to access, exchange, manipulate, and trade a large variety of multimedia items.

The International Telecommunication Union (ITU) Telecommunication Standardization Sector (ITU-T) has developed a series of standards H.26x for video phone and videoconference applications. H.261 supports data rates as multiples of 64Kbit/s, that is, $p\times$64Kbit/s, where $1 \le p \le 30$. H.261 only supports two image frame sizes, common interchange format (CIF) or 352×288 pixels, and quarter common interchange format (QCIF) or 176×144 pixels. H.262 is the same as the video part of MPEG-2. H.263 provides a number of improvements over H.261, MPEG-1, and MPEG-2. For example, it uses better methods for motion compensation, offers higher video quality, and supports more image sizes. H.264 is the same as MPEG-4 Part 10, advanced video coding (AVC), and is jointly developed by the ITU-T Video Coding Experts Group (VCEG) and MPEG. H.264/MPEG-4 AVC employs a number of new techniques, such as variable block-size motion compensation (VBSMC), to improve the compression performance. It is also more flexible under a variety of network environments. H.263 and H.264 have been used in 3GP movies for second-generation (2G) and third-generation (3G) mobile phones.

Similar to audio, video can also be streamed (Austerberry, 2005). This is especially useful for video phone calling, videoconferencing, and live

broadcasting. Current 3G mobile networks already offer video calls and many video-based entertainment programs, such as news and sports, which were only possible through TV before.

ANIMATION

Animation means presentation of a sequence of artificially created images. In video, the images are obtained from a camera, while in animation, the images are drawn by hand or generated by the computer. Moving pictures in animation are often synchronized with audio to create movies.

Cartoon movies had been used for entertainment long before the digital computer was invented. A cartoon film must contain 24 picture frames every second to show smooth motions (Chapman & Chapman, 2004). This means 86,400 pictures for a one-hour movie; obviously it is very labor intensive. The labor cost can be reduced using cel animation and key-frame animation techniques. In cel animation, the still background is drawn only once and the moving part is drawn frame by frame, each on a cel, a sheet of transparent material, which is placed on the background picture. In key-frame animation, a motion is decomposed into important key frames and in-betweens. Experienced animators are assigned to draw the key frames and junior animators the in-betweens. Now using the computer, the in-betweens can often be generated using pattern matching and interpolation techniques.

Simple animation can be displayed on the computer or mobile devices by simply going though a sequence of images. GIF provides such function. It is useful for small animated pictures, which does not require many colors or audio. It is widely used for Web page design and for MMS on mobile phones.

Simple animation can also be generated using morphing techniques. In Macromedia Flash, one shape can be morphed to another shape specified by a set of parameters. Each shape is described by its edges and color information. In this method, key frames are drawn according to shape specifications, and in-betweens are automatically generated by the computer through the morphing process.

Three-dimensional (3D) animation has been used in many digital entertainment products and services. In 3D animation, an object is often represented using a mesh model. It is shaded according to light and camera settings, and may be superimposed with a texture. Now there are a number of 3D design packages available for PCs as well as powerful workstations. Virtual reality (VR) systems make extensive use of 3D graphics and animation. The Virtual Reality Modeling Language (VRML) was developed to support VR on the Web (Ames, Nadeau, & Moreland, 1997).

An interesting and challenging task in computer animation is to automatically animate the human and animal faces (Huang & Yan, 2002, 2003; Parke & Waters, 1996; Yan, 2001). This involves synchronizing the mouth movement with voice and generating different facial expressions. We have recently developed a real-time lip synchronization and facial animation system, which has already been used by several Internet and communications companies for 3G and MMS applications on mobile phones (Tang, Liew, & Yan 2005). Our system can create many virtual characters with different styles. It can match voice signals with lip/mouth shapes smoothly and automatically. The lip-sync can be done in real time (e.g., 20 frames per second) for several languages, including Chinese (Cantonese and Mandarin), English, French, German, Japanese, and Spanish. In addition, a virtual character can express his/her emotion with different kinds of facial expressions. Examples of the movies produced by our system can be found on http://www.HyperAcademy.com or simply http://www.hy8.com.

TECHNOLOGY TRENDS

Mobile technology is rapidly advancing. We expect to see many new or enhanced mobile entertainment products and services in the next several years. First of all, future mobile devices will have higher computational power for its processors, higher resolution for digital cameras, and higher data rates through the telecommunications network. Currently, there is criticism for 3G mobile phones that the battery does not last long for displaying movies. To support multimedia functions for a longer period of usage, mobile devices need improved technologies for reduced power assumption and better batteries.

Traditionally, most multimedia contents based on graphics, video, and animation are produced for TV and other large display screens. Simple image down sampling of the images can cause visibility problems. So future multimedia editing and authoring tools should take into account the legibility of the material for mobile devices. An interesting research topic in image processing and pattern recognition is how to reduce the size of a bitmap image optimally so that the output is most legible. This requires sophisticated algorithms for feature detection and pattern extraction from the image.

More and more multimedia contents will become available for mobile devices in the future. Mobile gaming is one of the rapidly growing areas. There will also be increased use of mobile phones for music, movies, advertisements, news reports, storytelling, finance, weather and traffic information, and educational and training programs, and for access to the Web, most of which are similar to the capabilities and functions provided by TV and desktop computers. For Web applications, better user interface and page layout will be needed so that the users can find information needed easily. We also expect increased applications of video phone calls, videoconferencing, and video e-mail messages.

A more challenging task for a mobile device to perform is to recognize its user's voice, speech, face, and even facial expressions and emotions, and interact with the user. Considerable progress has been made in the past in these areas, but the recognition reliability still needs significant improvement. These problems can be solved to some extent under restricted conditions. For mobile phones, it is difficult to control the background noise or appearance for normal usages, so more robust pattern recognition techniques must be developed to solve these problems.

KEY TERMS

Audio Signal Processing: Acquisition, compression, enhancement, filtering, transformation, and transmission of sound data.

Computer Graphics: Modeling and rendering of two-dimensional or three-dimensional objects on the computer.

Digital Entertainment: Providing multimedia materials, such as music and movies, on digital devices, such as computers and mobile phones.

Facial Animation: Modeling and displaying talking human faces with different expressions.

Image Processing: Acquisition, compression, enhancement, filtering, transformation, and transmission of pictures.

Lip-Synchronization: Matching the mouth shape created by the computer with the voice signal.

Multimedia Content: Digital data of text, music, graphics, images, and video

Video Processing: Acquisition, compression, ehancement, filtering, transformation, and transmission of movies.

This work was previously published in Encyclopedia of Mobile Computing and Commerce, edited by D. Taniar, pp. 669-674, copyright 2007 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Chapter 3.4
Multimedia Information Design for Mobile Devices

Mohamed Ally
Athabasca University, Canada

INTRODUCTION

There is a rapid increase in the use of mobile devices such as cell phones, tablet PCs, personal digital assistants, Web pads, and palmtop computers by the younger generation and individuals in business, education, industry, and society. As a result, there will be more access of information and learning materials from anywhere and at anytime using these mobile devices. The trend in society today is learning and working on the go and from anywhere rather than having to be at a specific location to learn and work. Also, there is a trend toward ubiquitous computing, where computing devices are invisible to the users because of wireless connectivity of mobile devices. The challenge for designers is how to develop multimedia materials for access and display on mobile devices and how to develop user interaction strategies on these devices. Also, designers of multimedia materials for mobile devices must use strategies to reduce the user mental workload when using the devices in order to leave enough mental capacity to maximize deep processing of the information. According to O'Malley et al. (2003), effective methods for presenting information on these mobile devices and the pedagogy of mobile learning have yet to be developed. Recent projects have started research on how to design and use mobile devices in the schools and in society. For example, the MOBILearn project is looking at pedagogical models and guidelines for mobile devices to improve access of information by individuals (MOBILearn, 2004). This paper will present psychological theories for designing multimedia materials for mobile devices and will discuss guidelines for designing information for mobile devices. The paper then will conclude with emerging trends in the use of mobile devices.

BENEFITS AND LIMITATIONS OF MOBILE DEVICES

There are many benefits of using mobile devices in the workplace, education, and society. In mobile learning (m-learning), users can access information and learning materials from anywhere and at anytime. There are many definitions of m-learning in the field. M-learning is the use of electronic learning materials with built-in learning strategies for delivery on mobile computing devices to allow access from anywhere and at anytime (Ally, 2004a). Another definition of m-learning

is any sort of learning that happens when the learner is not at a fixed, predetermined location, or learning that happens when the learner takes advantage of the learning opportunities offered by mobile technologies (O'Malley et al., 2003). With the use of wireless technology, mobile devices do not have to be physically connected to networks in order to access information. Mobile devices are small enough to be portable, which allows users to take the device to any location to access information or learning materials. Because of the wireless connectivity of mobile devices, users can interact with other users from anywhere and at anytime to share information and expertise, complete a task, or work collaboratively on a project. Mobile devices have many benefits, because they allow for mobility while learning and working; however, there are some limitations of mobile devices that designers must be aware of when designing multimedia materials for delivery on mobile devices.

Some of the limitations of mobile devices in delivering multimedia materials include the small screen size for output of information, small input devices, low bandwidth, and challenges when navigating through the information (Ahonen et al., 2003). Designers of information and learning materials have to be aware of the limited screen size and input device when designing for usability. For example, rather than scrolling for more information on the screen, users of mobile devices must be able to go directly to the information and move back and forth with ease. Information should be targeted to the users' needs when they need it and should be presented efficiently to maximize the display on the mobile device. To compensate for the small screen size of mobile devices, multimedia materials must use rich media to convey the message to the user. For example, rather than present information in textual format, graphics and pictures can be used in such a way to convey the message using the least amount of text. For complex graphics, a general outline of the graphic should be presented on one screen with navigation tools to allow the user to see the details of the graphic on other screens. To present procedures and real-life situations, video clips can be used to present real-life simulations to the user. Also, the interface must be appropriate for individual users and the software system should be able to customize the interface based on individual users' characteristics. When developing multimedia materials for mobile devices, designers must be aware of psychological theories in order to guide the design.

PSYCHOLOGICAL THEORY FOR DEVELOPING MULTIMEDIA MATERIALS FOR MOBILE DEVICES

According to cognitive psychology, learning is an internal process, and the amount learned depends on the processing capacity of the user, the amount of effort expended during the learning process, the quality of the processing, and the user's existing knowledge structure (Ausubel, 1974). These have implications for how multimedia materials should be designed for mobile devices. Designers must include strategies that allow the user to activate existing cognitive structure and conduct quality processing of the information. Mayer et al. (2003) found that when a pedagogical agent was present on the screen as instruction was narrated to students, students who were able to ask questions and receive feedback interactively perform better on a problem-solving transfer test when compared to students who only received on-screen text with no narration. It appears that narration by a pedagogical agent encouraged deep processing, which resulted in higher-level learning. According to Paivio's theory of dual coding, memory is enhanced when information is represented both in verbal and visual forms (Paivio, 1986). Presenting materials in both textual and visual forms will involve more processing, resulting in

better storage and integration in memory (Mayer et al., 2004). Tabbers et al. (2004) found that in a Web-based multimedia lesson, students who received visual cues to pictures scored higher on a retention test when compared to students who did not receive the cues for the pictures. Also, strategies can be included to get the user to retrieve existing knowledge to process the information presented. For example, a comparative advance organizer can be used to activate existing knowledge structure to process the incoming information, or an expository advance organizer can be presented and stored in memory to help incorporate the details in the information (Ally, 2004a; Ausubel, 1974).

Constructivism is a theory of learning that postulates that learners are active during the learning process, and that they use their existing knowledge to process and personalize the incoming information. Constructivists claim that learners interpret information and the world according to their personal realities, and that they learn by observation, processing, and interpretation and then personalize the information into their existing knowledge bases (Cooper, 1993). Users learn best when they can contextualize what they learn for immediate application and to acquire personal meaning. According to Sharples (2000), mobile learning devices allow learners to learn wherever they are located and in their personal context so that the learning is meaningful. Also, mobile devices facilitate personalized learning, since learning is contextualized where learning and collaboration can occur from anywhere and anytime. According to constructivism, learners are not passive during the learning process. As a result, interaction on mobile devices must include strategies to actively process and internalize the information. For example, on a remote job site, a user can access the information using a mobile device for just-in-time training and then apply the information right away. As a result, designers must use instructional strategies to allow users to apply what they learn.

DESIGN GUIDELINES FOR MULTIMEDIA MATERIALS FOR MOBILE DEVICES

Cater for the User of Mobile Devices

- **Design for the User:** One of the variables that designers tend to ignore when they develop multimedia materials for mobile devices is the user of the devices. Different users have different learning styles; some users may be visual, while others may be verbal (Mayer & Massa, 2003). Users have different learning styles and preferences; strategies must be included and information presented in different ways in order to cater to the different learning styles and preferences (Ally & Fahy, 2002). Graphic overviews can be used to cater to users who prefer to get the big picture before they go into the details of the information. For active learners, information can be presented on the mobile device, and then the user can be given the opportunity to apply the information. For the creative users, there must be opportunities to apply the information in real-life applications so that they go beyond what was presented. The multimedia materials and information have to be designed with the user in mind in order to facilitate access, learning, and comprehension. Also, the user should have control of what he or she wants to access in order to go through the multimedia materials based on preferred learning styles and preferences. For users in remote locations with low bandwidth or limited wireless access, information that takes a long time to download should be redesigned to facilitate efficient download.
- **Adapt the Interface to the User:** An interface is required to coordinate interaction between the user and the information. To compensate for the small screen size of the display of the mobile device, the interface of

the mobile device must be designed properly. The interface can be graphical and should present limited information on the screen to prevent information overload in short-term memory. The system should contain intelligent software agents to determine what the user did in the past and to adapt the interface for future interaction with the information. The software system must be proactive by anticipating what the user will do next and must provide the most appropriate interface for the interaction to enhance learning. Users must be able to jump to related information without too much effort. The interface must allow the user to access the information with minimal effort and move back to previous information with ease. For sessions that are information-intense, the system must adjust the interface to prevent information overload. Some ways to prevent information overload include presenting less concepts on one screen or organizing the information in the form of concept maps to give the overall structure of the information and then presenting the details by linking to other screens with the details. The interface also must use good navigational strategies to allow users to move back and forth between displays. Navigation can also be automatic based on the intelligence gathered on the user's current progress and needs.

- **Design for Minimum Input:** Because of the small size of the input device, multimedia materials must be designed to require minimum input from users. Input can use pointing or voice input devices to minimize typing and writing. Because mobile devices allow access of information from anywhere at anytime, the device must have input and output options to prevent distractions when using the mobile devices. For example, if someone is using a mobile device in a remote location, it may be difficult to type on a keyboard or use a pointing device. The mobile technology must allow the user to input data using voice input or touch screen.
- **Build Intelligent Software Agents to Interact with the User:** Intelligent software systems can be built to develop an initial profile of the user and then present materials that will benefit the specific user, based on the user profile. As the intelligent agent interacts with the user, it learns about the user and adapts the format of the information, the interface, and the navigation pattern according to the user's style and needs. Knowing the user's needs and style will allow the intelligent software system to access additional materials from the Internet and other networks to meet the needs of user (Cook et al., 2004).
- **Use a Personalized Conversational Style:** Multimedia information and learning materials can be presented to the user in a personalized style or a formal style. In a learning situation, information should be presented in a personalized style, since the user of the mobile device may be in a remote location and will find this style more connected and personal. Mayer et al. (2004) found that students who received a personalized version of a narrated animation performed significantly better on a transfer test when compared to students who received a non-personalized, formal version of the narrated animation. They claimed that the results from the study are consistent with the cognitive theory of multimedia learning, where personalization results in students processing the information in an active way, resulting in higher-level learning and transfer to other situations.

Design to Improve the Quality of Information Processing on Mobile Devices

- **Chunk Information for Efficient Processing:** Designers of materials for mobile devices must use presentation strategies to enable users to process the materials efficiently because of the limited display capacity of mobile devices and the limited processing capacity of human working memory. Information should be organized or chunked in segments of appropriate and meaningful size to facilitate processing in working memory. An information session on a mobile device can be seen as consisting of a number of information objects sequenced in a predetermined way or sequenced based on the user needs. Information and learning materials for mobile devices should take the form of information and learning objects that are in an electronic format, reusable, and stored in a repository for access anytime and from anywhere (McGreal, 2004). Information objects and learning objects allow for instant assembly of learning materials by users and intelligent software agents to facilitate just-in-time learning and information access. The information can be designed in the form of information objects for different learning styles and characteristics of users (Ally, 2004b). The objects then are tested and placed in an electronic repository for just-in-time access from anywhere and at anytime using mobile devices.
- **Use High-Level Concept Maps to Show Relationships:** A concept map or a network diagram can be used to show the important concepts in the information and the relationship between the concepts rather than present information in a textual format. High-level concept maps and networks can be used to represent information spatially so that students can see the main ideas and their relationships (Novak, Gowin, & Johanse, 1983). Tusack (2004) suggests the use of site maps as the starting point of interaction that users can link back in order to continue with the information or learning session. Eveland et al. (2004) compared linear Web site designs and non-linear Web site designs and reported that linear Web site designs encourage factual learning, while non-linear Web site designs increase knowledge structure density. One can conclude that the non-linear Web site designs show the interconnection of the information on the Web site, resulting in higher-level learning.

EMERGING TRENDS IN DESIGNING MULTIMEDIA MATERIALS FOR MOBILE DEVICES

The use of mobile devices with wireless technology allow access of information and multimedia materials from anywhere and anytime and will dramatically alter the way we work and conduct business and how we interact with each other (Gorlenko & Merrick, 2003). For example, mobile devices can make use of Global Positioning Systems to determine where users are located and connect them with users in the same location so that they can work collaboratively on projects and learning materials. There will be exponential growth in the use of mobile devices to access information and learning materials, since the cost of the devices will be lower than desktop computers, and users can access information from anywhere and at anytime. Also, the use of wireless mobile devices would be more economical, since it does not require the building of the infrastructure to wire buildings. The challenge for designers of multimedia materials for mobile devices is how to standardize the design for use by different types of devices. Intelligent software agents should be

built into mobile devices so that most of the work is done behind the scenes, minimizing input from users and the amount of information presented on the display of the mobile devices. Because mobile devices provide the capability to access information from anywhere, future multimedia materials must be designed for international users.

CONCLUSION

In the past, the development of multimedia materials and mobile devices concentrated on the technology rather than the user. Future development of multimedia materials for mobile devices should concentrate on the user to drive the development and delivery (Gorlenko & Merrick, 2003). Mobile devices can be used to deliver information and learning materials to users, but the materials must be designed properly in order to compensate for the small screen of the devices and the limited processing and storage capacity of a user's working memory. Learning materials need to use multimedia strategies that are information-rich rather than mostly text.

KEY TERMS

Advance Organizer: A general statement at the beginning of the information or lesson to activate existing cognitive structure or to provide the appropriate cognitive structure to learn the details in the information or the lesson.

Concept Map: A graphic outline that shows the main concepts in the information and the relationship between the concepts.

Intelligent Software Agent: A computer application software that is proactive and capable of flexible autonomous action in order to meet its design objectives set out by the designer. The software learns about the user and adapts the interface and the information to the user's needs and style.

Interface: The components of the computer program that allow the user to interact with the information.

Learning Object: A digital resource that is stored in a repository that can be used and reused to achieve a specific learning outcome or multiple outcomes (Ally, 2004b).

Learning Style: A person's preferred way to learn and process information, interact with others, and complete practical tasks.

Mobile Device: A device that can be used to access information and learning materials from anywhere and at anytime. The device consists of an input mechanism, processing capability, storage medium, and display mechanism.

Mobile Learning (M-Learning): Electronic learning materials with built-in learning strategies for delivery on mobile computing devices to allow access from anywhere and at anytime.

Multimedia: A combination of two or more media to present information to users.

Short-Term Memory: The place where information is processed before the information is transferred to long-term memory. The duration of short-term memory is very short, so information must be processed efficiently to maximize transfer to long-term memory.

Ubiquitous Computing: Computing technology that is invisible to the user because of wireless connectivity and transparent user interface.

User: An individual who interacts with a computer system to complete a task, learn specific knowledge or skills, or access information.

Wearable Computing Devices: Devices that are attached to the human body so that the hands are free to complete other tasks.

Chapter 3.5
Multimedia over Wireless Mobile Data Networks

Surendra Kumar Sivagurunathan
University of Oklahoma, USA

Mohammed Atiquzzaman
University of Oklahoma, USA

ABSTRACT

With the proliferation of wireless data networks, there is an increasing interest in carrying multimedia over wireless networks using portable devices such as laptops and personal digital assistants. Mobility gives rise to the need for handoff schemes between wireless access points. In this chapter, we demonstrate the effectiveness of transport layer handoff schemes for multimedia transmission, and compare with Mobile IP, the network layer-based industry standard handoff scheme.

INTRODUCTION

Mobile computers such as personal digital assistants (PDA) and laptop computers with multiple network interfaces are becoming very common. Many of the applications that run on a mobile computer involve multimedia, such as video conferencing, audio conferencing, watching live movies, sports, and so forth. This chapter deals with multimedia communication in mobile wireless devices, and, in particular, concentrates on the effect of mobility on streaming multimedia in wireless networks.

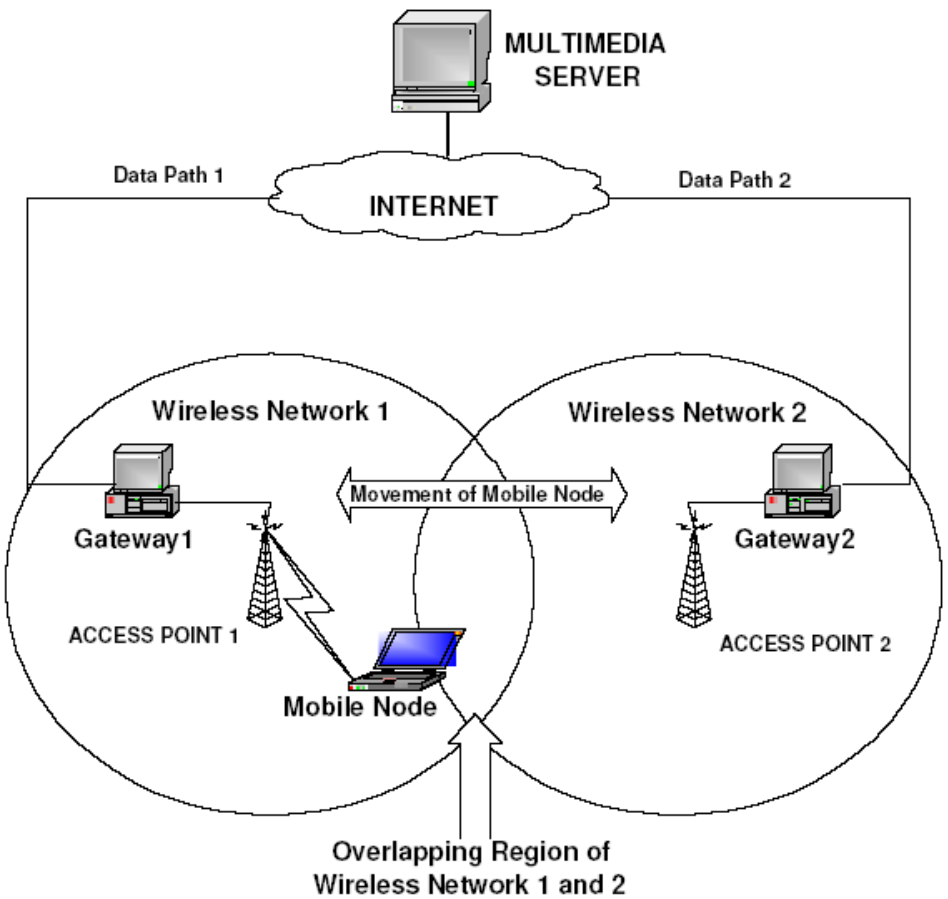
Streaming multimedia over wireless networks is a challenging task. Extensive research has been carried out to ensure a smooth and uninterrupted multimedia transmission to a mobile host (MH) over wireless media. The current research thrust is to ensure an uninterrupted multimedia transmission when the MH moves between networks or subnets. Ensuring uninterrupted multimedia transmission during handoff is challenging because the MH is already receiving multimedia from the network to which it is connected; when it moves into another network, it needs to break the connection with the old network and establish a connection with the new network. Figure 1 shows an MH connected to Wireless Network

1; when it moves, it has to make a connection with the new network, say Wireless Network 2. The re-establishment of a new connection takes a considerable amount of time, resulting in the possibility of interruption and resulting loss of multimedia.

The current TCP/IP network infrastructure was not designed for mobility. It does not support handoff between IP networks. For example, a device running a real-time application, such as video conference, cannot play smoothly when the user hands off from one wireless IP network to another, resulting in unsatisfactory performance to the user.

Mobile IP (MIP) (Perkins, 1996), from the Internet Engineering Task Force (IETF), addresses the mobility problem. MIP extends the existing IP protocol to support host mobility, including handoff, by introducing two network entities: home agent (HA) and foreign agent (FA). The HA and FA work together to achieve host mobility. The correspondent node (CN) always communicates with the mobile node (MN) via its home network address, even though MH may not dwell in the home network. For CN to have seamless access to MN, the MH has to be able to handoff in a timely manner between networks.

Figure 1. Illustration of handoff with mobile node connected to Wireless Network 1



Handoff latency is one of the most important indicators of handoff performance. Large handoff latency degrades performance of real-time applications. For example, large handoff latency will introduce interruption in a video conference due to breaks in both audio and video data transmission. In addition to high handoff latency, MIP suffers from a number of other problems including triangle routing, high signaling traffic with the HA, and so forth. A number of approaches to reduce the MIP handoff latency are given next.

Mobile IP uses only one IP; a certain amount of latency in data transmission appears to be unavoidable when the MH performs a handoff. This is because of MN's inability to communicate with the CN through either the old path (because it has changed its wireless link to a new wireless network) or the new path (because HA has not yet granted its registration request). Thus, MH cannot send or receive data to or from the CN while the MH is performing registration, resulting in interruption of data communication during this time interval. This interruption is unacceptable in a real-world scenario, and may hinder the widespread deployment of real-time multimedia applications on wireless mobile networks. Seamless IP-diversity based generalized mobility architecture (SIGMA) overcomes the issue of discontinuity by exploiting multi-homing (Stewart, 2005) to keep the old data path alive until the new data path is ready to take over the data transfer, thus achieving lower latency and lower loss during handoff between adjacent subnets than Mobile IP.

The *objective* of this chapter is to demonstrate the effectiveness of SIGMA in reducing handoff latency, packet loss, and so forth, for multimedia transmission, and compare with that achieved by Mobile IP. The *contribution* of this chapter is to describe the implementation of a real-time streaming server and client in SIGMA to achieve seamless multimedia streaming during handoff. SIGMA *differs* from previous work in the sense that all previous attempts modified the hardware, infrastructure of the network, server, or client to achieve seamless multimedia transmission during handoff.

The rest of this chapter is organized as follows. Previous work on multimedia over wireless networks is described in the next section. The architecture of SIGMA is described in the third section, followed by the testbed on which video transmission has been tested for both MIP and SIGMA in the fourth section. Results of video over MIP and SIGMA and presented and compared in the fifth section, followed by conclusions in the last section.

BACKGROUND

A large amount of work has been carried out to improve the quality of multimedia over wireless networks. They can be categorized into two types:

- Studies related to improving multimedia (e.g., video or audio) over wireless networks. They do not consider the mobility of the MN, but attempt to provide a high quality multimedia transmission within the same wireless network for stationary servers and clients.
- Studies related to achieving seamless multimedia transmission during handoffs. They consider mobility of the MH and try to provide a seamless and high quality multimedia transmission when the MH (client) moves from one network to another.

Although our interest in this chapter is seamless multimedia transmission during handoffs, we describe previous work on both categories in the following sections.

Multimedia over Wireless Networks

Ahmed, Mehaoua, and Buridant (2001) worked on improving the quality of MPEG-4 transmis-

sion on wireless using differentiated services (Diffserv). They investigated QoS provisioning between MPEG-4 video application and Diffserv networks. To achieve the best possible QoS, all the components involved in the transmission process must collaborate. For example, the server must use stream properties to describe the QoS requirement for each stream to the network. They propose a solution by distinguishing the video data into important video data and less important video data (such as complementary raw data). Packets which are marked as less important are dropped in the first case if there is any congestion, so that the receiver can regenerate the video with the received important information.

Budagavi and Gibson (2001) improved the performance of video over wireless channels by multiframe video coding. The multiframe coder uses the redundancy that exists across multiple frames in a typical video conferencing sequence so that additional compression can be achieved using their multiframe-block motion compensation (MF-BMC) approach. They modeled the error propagation using the Markov chain, and concluded that use of multiple frames in motion increases the robustness. Their proposed MF-BMC scheme has been shown to be more robust on wireless networks when compared to the base-level H.263 codec which uses single frame-block motion compensation (SF-BMC).

There are a number of studies, such as Stedman, Gharavi, Hanzo, and Steele (1993), Illgner and Lappe (1995), Khansari, Jalai, Dubois, and Mermelstein (1996), and Hanzo and Streit (1995), which concentrate on improving quality of multimedia over wireless networks. Since we are only interested in studies that focus on achieving seamless multimedia transmission during handoff, we do not go into details of studies related to multimedia over wireless networks. Interested readers can use the references given earlier in this paragraph.

Seamless Multimedia over Mobile Networks

Lee, Lee, and Kim (2004) achieved seamless MPEG-4 streaming over a wireless LAN using Mobile IP. They achieved this by implementing packet forwarding with buffering mechanisms in the foreign agent (FA) and performed pre-buffering adjustment in a streaming client. Insufficient pre-buffered data, which is not enough to overcome the discontinuity of data transmission during the handoff period, will result in disruption in playback. Moreover, too much of pre-buffered data wastes memory and delays the starting time of playback. Find the optimal pre-buffering time is, therefore, an important issue in this approach.

Patanapongpibul and Mapp (2003) enable the MH to select the best point of attachment by having all the reachable router advertisements (RA) in a RA cache. RA cache will have the entire router's link whose advertisements are heard by the mobile node. These RAs are arranged in the cache according to a certain priority. The priority is based on two criteria: (1) the link signal strength, that is, signal quality and SNR level, and (2) the time since the RA entry was last updated. So the RAs with highest router priority are forwarded to the IP packet handler for processing. The disadvantage of this method includes extra memory for the RA cache.

Pan, Lee, Kim, and Suda (2004) insert four components in the transport layer of the video server and the client. These four components are: (1) a path management module, (2) a multipath distributor module at the sender, (3) a pair of rate control modules, and (4) a multipath collector module at the receiver. They achieve a seamless video by transferring the video over multiple paths to the destination during handoffs. The overhead of the proposed scheme is two-fold: reduction in transmission efficiency due to transmission of duplicated video packets and transmission of control packets associated with the proposed

scheme, and processing of the proposed scheme at the sender and receiver.

Boukerche, Hong, and Jacob (2003) propose a two-phase handoff scheme to support synchronization of multimedia units (MMU) for wireless clients and distributed multimedia systems. This scheme is proposed for managing MMUs to deliver them to mobile hosts on time. The two-phase scheme consists of: setup handoff and end handoff. In the first phase, setup handoff procedure has two major tasks: updating new arrival BSs and maintaining the synchronization for newly arrived mobile hosts (MHs). If an MH can reach another BS, then MH reports "new BS arrived" to its primary BS. End handoff procedure deals with the ordering of MMUs and with the flow of MMUs for a new MH. Any base station can be a new primary base station. The algorithm notifies MHs, BSs, and servers, and then chooses the closest common node from the current primary base station and new base stations. This method suffers from the disadvantage of additional overhead of updating the base station (BS) with newly arrived BSs and ordering of MMUs.

SIGMA FOR SEAMLESS MULTIMEDIA IN MOBILE NETWORKS

Limitations of previously proposed schemes in achieving seamless multimedia transmission during handoff in a wireless environment have been discussed in the previous section. In this section, we will discuss our proposed handoff scheme, called SIGMA, which has been designed for seamless multimedia transmission during handoffs, followed by its advantages over previous schemes.

Introduction to SIGMA

To aid the reader in getting a better understanding of SIGMA, in this section, we describe the various steps involved in a SIGMA handoff. A detailed description of SIGMA can be found in Fu, Ma, Atiquzzaman, and Lee (2005). We will use the stream control transmission protocol (Stewart, 2005), a new emerging transport layer protocol from IETF, to illustrate SIGMA.

Stream control transmission protocol's (SCTP) multi-homing (see Figure 2) allows an association between two endpoints to span across multiple IP addresses or network interface cards. One of the addresses is designated as the primary while the other can be used as a backup, in the case of failure of the primary address, or when the upper layer application explicitly requests the use of the backup. Retransmission of lost packets can also be done over the secondary address. The built-in support for multi-homed endpoints by SCTP is especially useful in environments that require high-availability of the applications, such as Signaling System 7 (SS7) transport. A multi-homed SCTP association can speedup recovery from link failure situations without interrupting any ongoing data transfer. Figure 2 presents an example of SCTP multi-homing where two nodes, CN and MH, are connected through two wireless networks, with MH being multi-homed. One of MN's IP addresses is assigned as the primary address for use by CN for transmitting data packets; the other IP address can be used as a backup in case of primary address failure.

STEP 1: Obtain New IP Address

Referring to Figure 2, the handoff preparation procedure begins when the MH moves into the overlapping radio coverage area of two adjacent subnets. Once the MH receives the router advertisement from the new access router (AR2), it should initiate the procedure of obtaining a new IP address (IP2 in Figure 2). This can be accomplished through several methods: DHCP, DHCPv6, or IPv6 Stateless Address Autoconfiguration (SAA) (Thomson & Narten, 1998). The main difference between these methods lies in whether the IP ad-

dress is generated by a server (DHCP/DHCPv6) or by the MH itself (IPv6 SAA). For cases where the MH is not concerned about its IP address but only requires the address to be unique and routable, IPv6 SAA is a preferred method for SIGMA to obtain a new address since it significantly reduces the required signaling time.

STEP 2: Add IP Addresses to Association

When the SCTP association is initially setup, only the CN's IP address and the MH's first IP address (IP1) are exchanged between CN and MH. After the MH obtains another IP address (IP2 in STEP 1), MH should bind IP2 into the association (in addition to IP1) and notify CN about the availability of the new IP address (Fu, Ma, Atiquzzaman, & Lee, 2005).

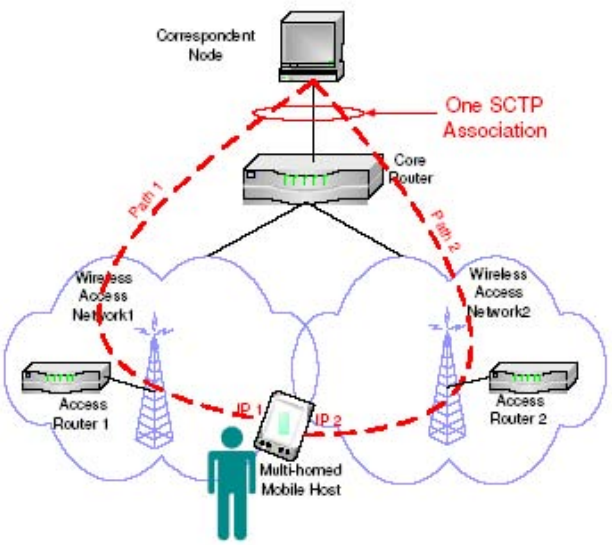
SCTP provides a graceful method to modify an existing association when the MH wishes to notify the CN that a new IP address will be added to the association and the old IP addresses will probably be taken out of the association. The IETF Transport Area Working Group (TSVWG) is working on the "SCTP Address Dynamic Reconfiguration" Internet draft (Stewart, 2005), which defines two new chunk types (ASCONF and ASCONF-ACK) and several parameter types (Add IP Address, Delete IP address, Set Primary Address, etc.). This option will be very useful in mobile environments for supporting service reconfiguration without interrupting on-going data transfers.

In SIGMA, MH notifies CN that IP2 is available for data transmission by sending an ASCONF chunk to CN. On receipt of this chunk, CN will add IP2 to its local control block for the association and reply to MH with an ASCONF-ACK chunk indicating the success of the IP addition. At this time, IP1 and IP2 are both ready for receiving data transmitted from CN to MH.

STEP 3: Redirect Data Packets to New IP Address

When MH moves further into the coverage area of wireless access network2, data path2 becomes increasingly more reliable than data path1. CN can then redirect data traffic to the new IP address

Figure 2. An SCTP association featuring multi-homing



(IP2) to increase the possibility of data being delivered successfully to the MH. This task can be accomplished by the MH sending an ASCONF chunk with the Set-Primary-Address parameter, which results in CN setting its primary destination address to MH as IP2.

STEP 4: Updating the Location Manager

SIGMA supports location management by employing a location manager that maintains a database which records the correspondence between MH's identity and current primary IP address (Reaz, Atiquzzaman, & Fu, 2005). MH can use any unique information as its identity, such as the home address (as in MIP), domain name, or a public key defined in the public key infrastructure (PKI).

Following our example, once the Set-Primary-Address action is completed successfully, MH should update the location manager's relevant entry with the new IP address (IP2). The purpose of this procedure is to ensure that after MH moves from the wireless access network1 into network2, further association setup requests can be routed to MH's new IP address IP2. This update has no impact on existing active associations.

We can observe an important difference between SIGMA and MIP: the location management and data traffic forwarding functions are coupled together in MIP, whereas they are *decoupled in SIGMA to speedup handoff and make the deployment more flexible*.

STEP 5: Delete or Deactivate Obsolete IP Address

When MH moves out of the coverage of wireless access network1, no *new* or *retransmitted* data packets should be directed to address IP1. In SIGMA, MH can notify CN that IP1 is out of service for data transmission by sending an ASCONF chunk to CN (Delete IP Address). Once received, CN will delete IP1 from its local association control block and reply to MH with an ASCONF-ACK chunk indicating the success of the IP deletion.

A less aggressive way to prevent CN from sending data to IP1 is for the MH to advertise a zero receiver window (corresponding to IP1) to CN (Goff, Moronski, Phatak, & Gupta, 2000). This will give CN an impression that the interface (on which IP1 is bound) buffer is full and cannot receive any more data. By deactivating instead of deleting the IP address, SIGMA can adapt more gracefully to MH's zigzag (often referred to as ping pong) movement patterns and reuse the previously obtained IP address (IP1), as long as the lifetime of IP1 has not expired. This will reduce the latency and signaling traffic that would have otherwise been caused by obtaining a new IP address.

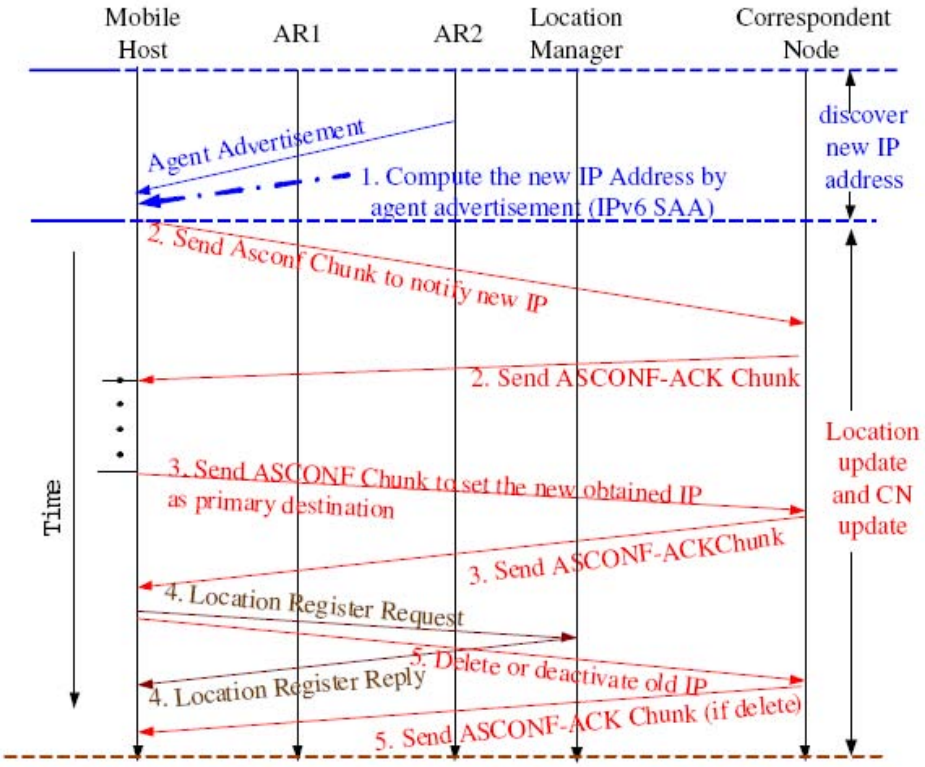
Timing Diagram of SIGMA

Figure 3 summarizes the signaling sequences involved in SIGMA. Here we assume IPv6 SAA and MH initiated Set-Primary-Address. Timing diagrams for other scenarios can be drawn similarly, but are not shown here because of space limitations. In this figure, the numbers before the events correspond to the step numbers in the previous sub-sections, respectively.

Advantages of SIGMA over the Previous Works

A number of previous work have considered seamless multimedia transmission during handoff, as mentioned in the second section, which have their own disadvantages. Here, we discuss the advantages of SIGMA over previous work. Lee et al. (2004) performed pre-buffering adjustment in client. Playback disruption may occur if the pre-buffered data is not enough to overcome the discontinuity of data transmission that occurs during handoff. Moreover, excessive pre-buffered

Figure 3. Timeline of signaling in SIGMA



data wastes memory usage and delays the starting time of playback. Find the optimal pre-buffering time is an important issue in this approach. Since SIGMA does not pre-buffer any data in the client, such optimization issues are not present in SIGMA.

Patanapongpibul et al. (2003) use the router advertisement (RA) cache. The disadvantage of this method is that it needs extra memory for RA cache; SIGMA does not involve any caching and hence does not suffer from such memory problems. Pan et al. (2004) use multipath (as discussed earlier), which suffers from (1) reduction in bandwidth efficiency due to transmission of duplicated video packets and transmission of control packets associated with the proposed scheme, and (2) processing overhead at the sender and receiver. Absence of multipaths or duplicate video packets in SIGMA results in higher link bandwidth efficiency.

Boukerche et al. (2003) proposed a two-phase handoff scheme which has additional overhead of updating the base station (BS) with newly arrived BSs, and also ordering of multimedia units (MMUs). In SIGMA, there is no feedback from MH to any of the base stations, and hence does not require ordering of multimedia units or packets.

EXPERIMENTAL TESTBED

Having reviewed the advantages of SIGMA over other schemes for multimedia transmission in the previous section, in this section, we present experimental results for SIGMA as obtained from an experimental setup we have developed

at the University of Oklahoma. We compare the results of handoff performance during multimedia transmission over both SIGMA and Mobile IP. To make a fair comparison, we have used the same test bed for both MIP and SIGMA. Figure 4 (to be described later) shows the topology of our test bed, which has been used by a number of researchers—Seol, Kim, Yu, and Lee (2002), Wu, Banerjee, Basu, and Das (2003), Onoe, Atsumi, Sato, and Mizuno (2001)—for measurement of handoff performance. The difference in data communication between the CN and the MH for MIP and SIGMA lies in the lower layer sockets: the file sender for MIP is based on the regular TCP socket, while that for SIGMA is based on SCTP socket. We did not use the traditional *ftp* program for file transfer because it was not available for the SCTP protocol. To obtain access to the SCTP socket, we used Linux 2.6.2 kernel with Linux Kernel SCTP (LKSCTP) version 2.6.2-0.9.0 on both CN and MN. A number of MIP implementations, such as HUT Dynamics (HUT), Stanford Mosquito (MNET), and NUS Mobile IP (MIP), are publicly available. We chose HUT Dynamics for testing MIP in our test bed due to the following reasons: (1) Unlike Stanford Mosquito, which integrates the FA and MN, HUT Dynamics implements HA, FA, and MH daemons separately. This architecture is similar to SIGMA where the two access points and MH are separate entities. (2) HUT Dynamics implements hierarchical FAs, which will allow future comparison between SIGMA and hierarchical Mobile IP. Our MIP testbed consists four nodes: correspondent node (CN), foreign agent (FA), home agent (HA), and mobile node (MN). All the nodes run corresponding agents developed by HUT Dynamics. The hardware and software configuration of the nodes are given in Table 1.

The CN and the machines running the HA and FA are connected to the Computer Science (CS) network of the University of Oklahoma, while the MH and access points are connected to two separate private networks. The various IP addresses are shown in Table 2. IEEE 802.11b is used to connect the MH to the access points.

The network topology of SIGMA is similar to the one of Mobile IP except that there is no HA or FA in SIGMA. As shown in Figure 4, the machines which run the HA and FA in the case of MIP act as gateways in the case of SIGMA. Table 1 shows the hardware and software configuration for the SIGMA experiment. The various IP addresses are shown in Table 2. The experimental procedure of Mobile IP and SIGMA is given next:

Table 1. Mobile IP and SIGMA testbed configurations

Node	**Hardware**	**Software**	**Operating System**
Home Agent(MIP) Gateway1 (SIGMA)	Desktop, two NICs	HUT Dynamics 0.8.1 Home Agent Daemon (MIP)	Redhat Linux 9 kernel 2.4.20
Foreign Agent (MIP) Gateway2 (SIGMA)	Desktop, two NICs	HUT Dynamics 0.8.1 Foreign Agent Daemon (MIP)	Redhat Linux 9 kernel 2.4.20
Mobile Node	Dell Inspiron- 1100 Laptop, one Avaya 802.11b wireless card	HUT Dynamics 0.8.1 Mobile Node Daemon (MIP), File receiver	Redhat Linux 9 kernel 2.4.20
Correspondent Node	Desktop, one NIC	File sender	Redhat Linux 9 2.6.20

Table 2. Mobile IP and SIGMA network configurations

Node	Network Configuration
Home Agent (MIP) Gateway1 (SIGMA)	eth0: 129.15.78.171, gateway 129.15.78.172; eth1:10.1.8.1
Foreign Agent (MIP) Gateway2 (SIGMA)	eth0: 129.15.78.172 gateway 129.15.78.171; eth1: 10.1.6.1
Mobile Node	Mobile IP's Home Address: 10.1.8.5 SIGMA's IP1: 10.1.8.100 SIGMA's IP2 : 10.1.6.100
Correspondent Node	129.15.78.150

1. Start with the MH in Domain 1.
2. **For Mobile IP:** Run HUT Dynamics daemons for HA, FA, and MN. **For SIGMA:** Run the SIGMA handoff program, which has two functions: (1) monitoring the link layer signal strength to determine the time to handoff, and (2) carrying out the signaling shown in Figure 4.
3. Run file sender/video server and file receiver/video client (using TCP sockets for Mobile IP, using SCTP sockets for SIGMA) on CN and MN, respectively.
4. Run Ethereal (ETHEREAL) on the CN and MH to capture packets.
5. Move MH from Domain 1 to Domain 2 to perform handoff by Mobile IP and SIGMA. Capture all packets sent from CN and received at MN.

RESULTS

Various results were collected on the experimental setup and procedure described earlier. In this section, we present two kinds of results: file transfer and multimedia transmission. The reason for showing the results of file transfer is to prove that SIGMA achieves seamless handoff not only for multimedia but also for file transfers.

Results for File Transfer

In this section, we present and compare the results of handoffs using MIP and SIGMA for file transfer. For comparison, we use throughput, RTT, and handoff latency as the performance measures. *Throughput* is measured by the rate at which packets are received at the MN. *RTT* is the time required for a data packet to travel from the source to the destination and back. We define *handoff latency* as the time interval between the MH receiving the last packet from Domain 1 (previous network) and the first packet from Domain 2 (the new network). The experimental results are described next.

Results from Mobile IP Handoff

Figure 5 shows the throughput during Mobile IP handoff between Domain 1 and Domain 2. The variations in throughput within HA (from 20 second to 30 second) and within FA (from 37 second to 60 second) are due to network congestion arising from cross traffic in the production CS network.

The average throughput before, during and after handoff are 2.436 Mbps, 0 Mbps and 2.390 Mbps, respectively. Figure 6 shows the packet trace during MIP handoff. The actual handoff latency for MIP can be clearly calculated by having a zoomed-in view of the packet trace graph. Figure 7 shows a zoomed-in view of the packet trace, where the calculated handoff latency is eight seconds for Mobile IP. Figure 8 shows the RTT for the MIP handoff. As we can see, the RTT is high for eight seconds (the handoff latency time), during the handoff.

Figure 4. SIGMA and Mobile IP testbed

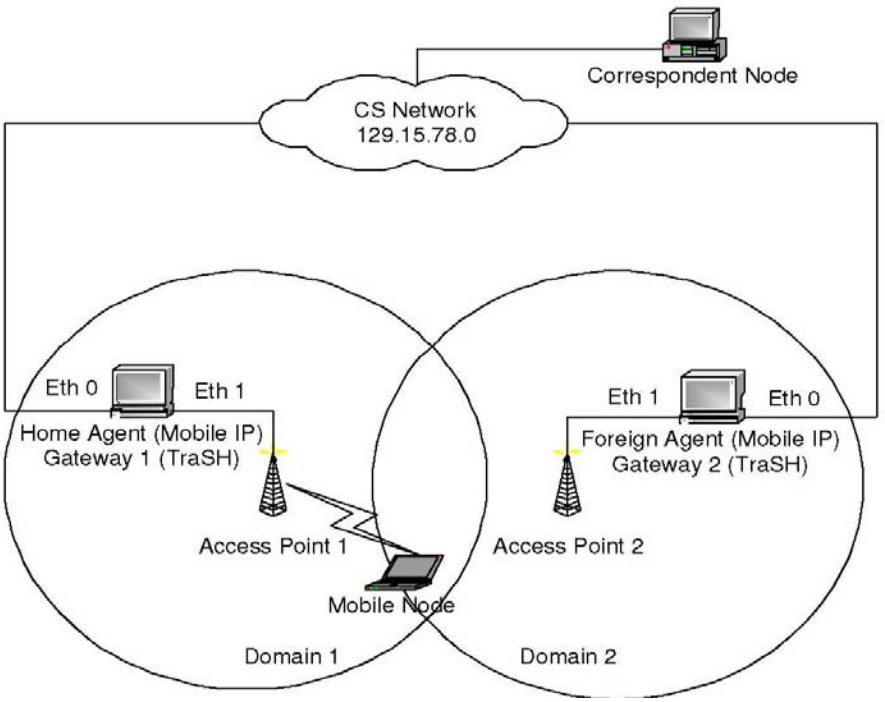


Figure 5. Throughput during MIP handoff

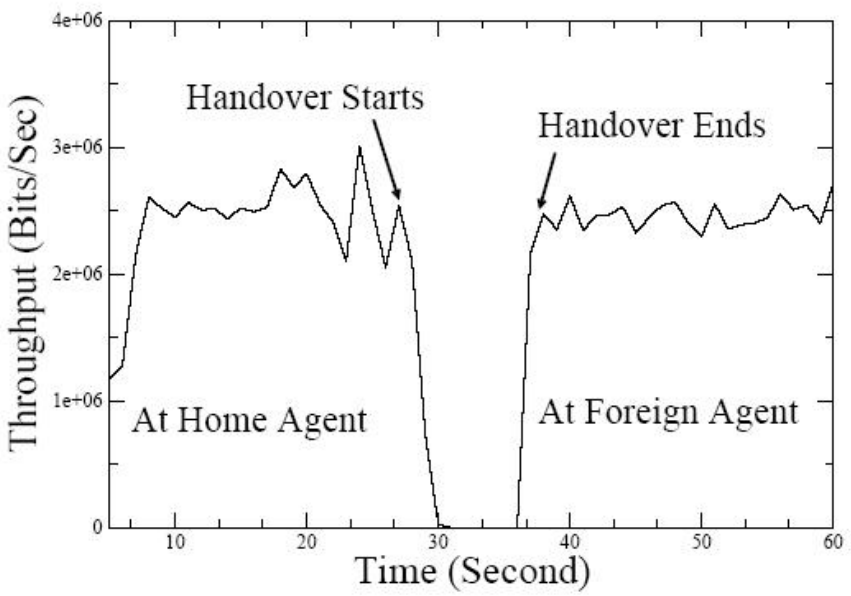

Figure 6. Packet trace during MIP handoff

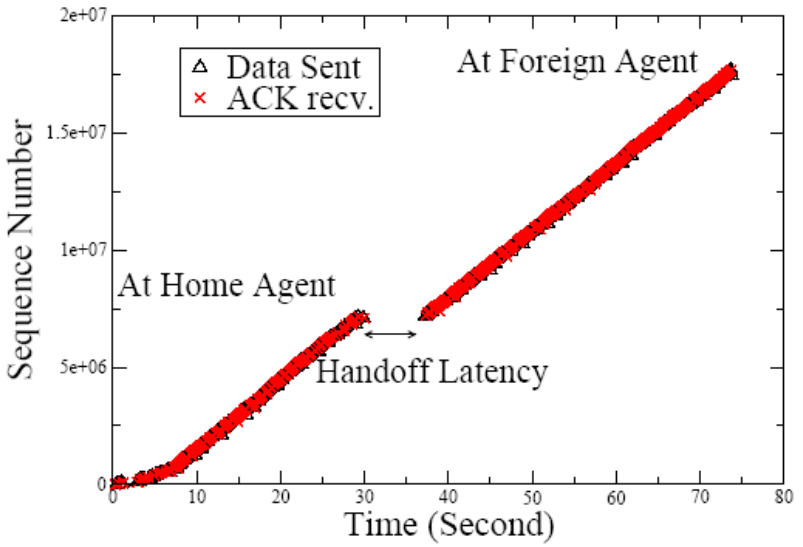

Figure 7. Zoomed in view during MIP handoff instant

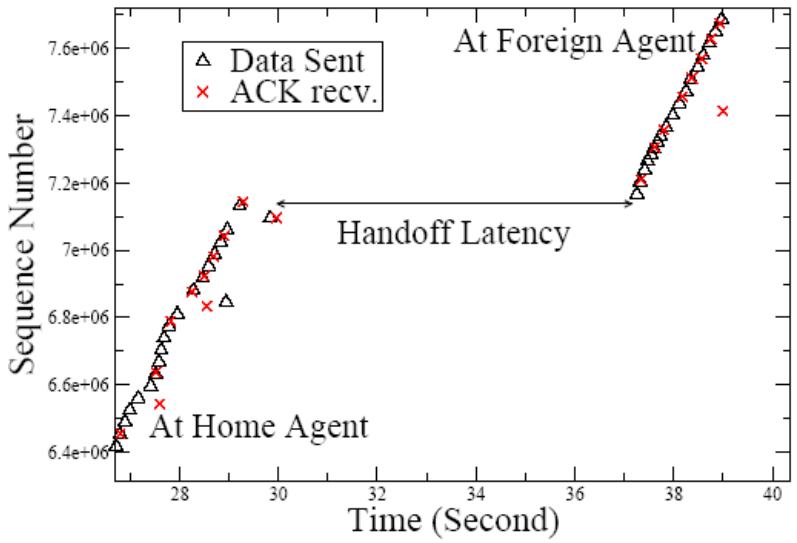
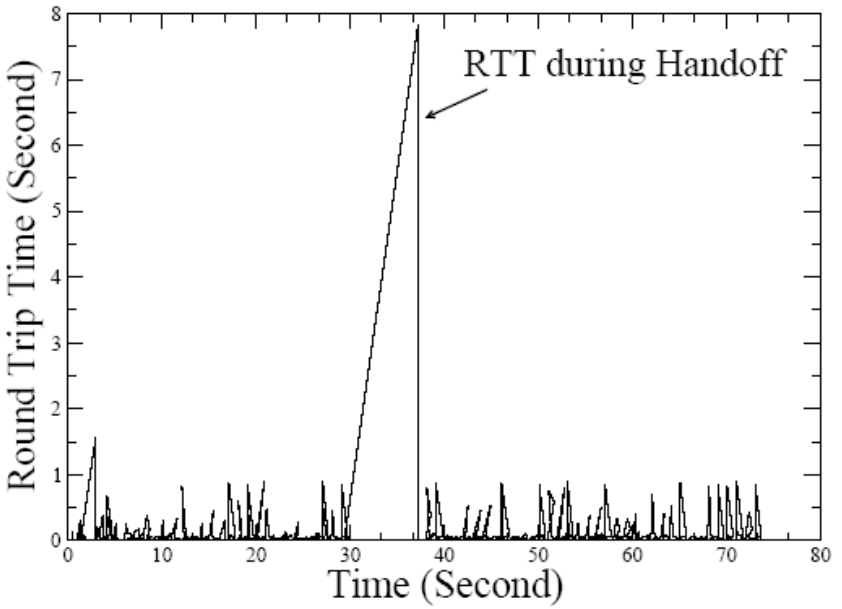


The registration time (or registration latency) is also a part of the handoff latency. Registration latency, the time taken by the MH to register with the agent (HA or FA), is calculated as follows. Ethereal capture showed that the MH sent a registration request to the HA at time t = 14.5123 second and received a reply from the HA at t = 14.5180 second. Hence, the calculated registration time for registering with HA is 5.7 milliseconds. Similarly, during MIP handoff, Ethereal capture showed that the MH sent a registration request to FA at time t =7.1190 second and received a reply from the FA at t =7.2374, resulting in a registration time of 38.3 milliseconds. This is due to the fact that after the MH registers with the HA, it can directly register with the HA. On the other hand, if it registers with the FA, the MH registers each new care-of-address with its HA possibly

Figure 8. RTT during MIP handoff



through FA. The registration latency is, therefore, higher when the MH is in the FA.

Results from SIGMA Handoff

Figure 9 shows the throughput during SIGMA handoff where it can observed that the throughput does not go to zero. The variation in throughput is due to network congestion arising from cross traffic in the production CS network. Although we cannot see the handoff due to it being very small, it should be emphasized that the ethereal capture showed the handoff starting and ending at t = 60.755 and t = 60.761 seconds, respectively, that is, a handoff latency of six milliseconds.

Figure 10 shows the packet trace during SIGMA handoff. It can be seen that packets arrive at the MH without any gap or disruption; this is also a powerful proof of SIGMA's smoother handoff as compared to handoff in Mobile IP. This experimentally demonstrates that *a seamless handoff can be realized with SIGMA.* Figure 11 shows a zoomed-in view of the packet trace during the SIGMA handoff period; a handoff latency of six milliseconds can be seen between the packets arriving at the old and new paths.

Figure 12 shows the RTT during SIGMA handoff. A seamless handoff is evident from the absence of any sudden RTT increase during handoff.

Result of Multimedia Data Transfer

To test the handoff performance for multimedia over SIGMA, we used a streaming video client and a streaming server at the MH and CN, respectively (details in the fourth section). Apple's Darwin Streaming Server (DARWIN) and CISCO's MPEG4IP player (MPEG) were modified to stream data over SCTP. A seamless handoff, with no interruption in the video stream, was achieved with SIGMA.

Figure 13 shows the throughput of multimedia (video) data, when the MH moves between subnets. The connection request and setup between the client and server is carried out during the first 10 seconds. It can be seen that the throughput does not drop during handoff at time = 31 second

Figure 9. Throughput during SIGMA handoff

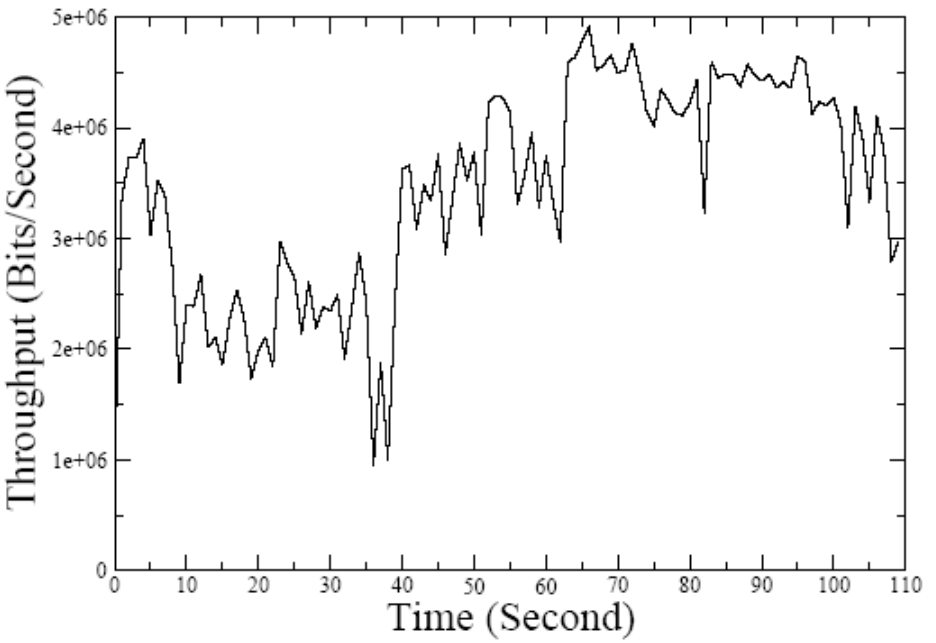


Figure 10. Packet trace during SIGMA handoff

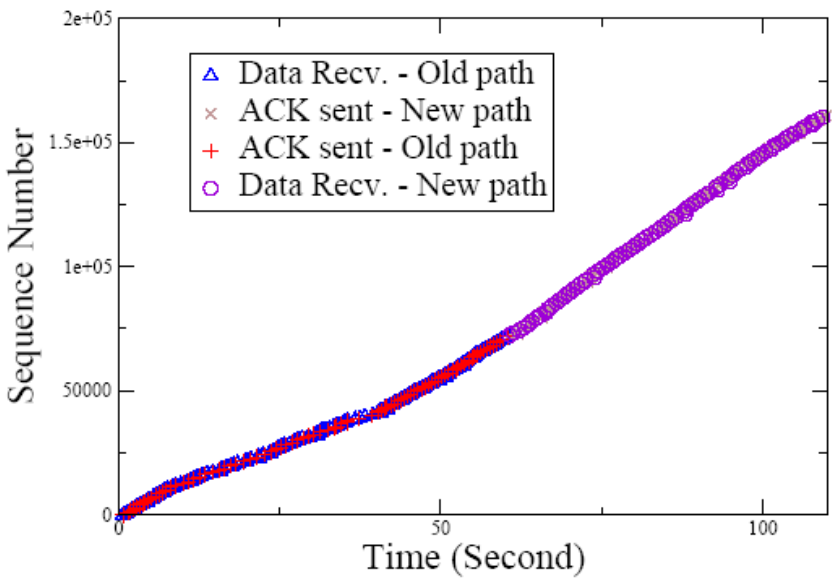

Figure 11. Zoomed in view during SIGMA handoff

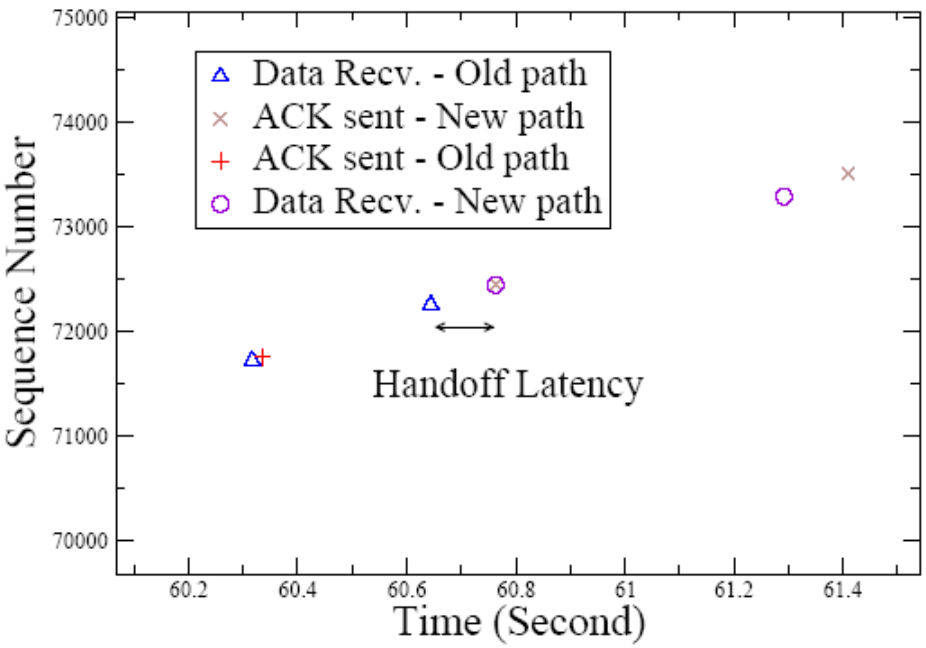

Figure 12. RTT during SIGMA handoff

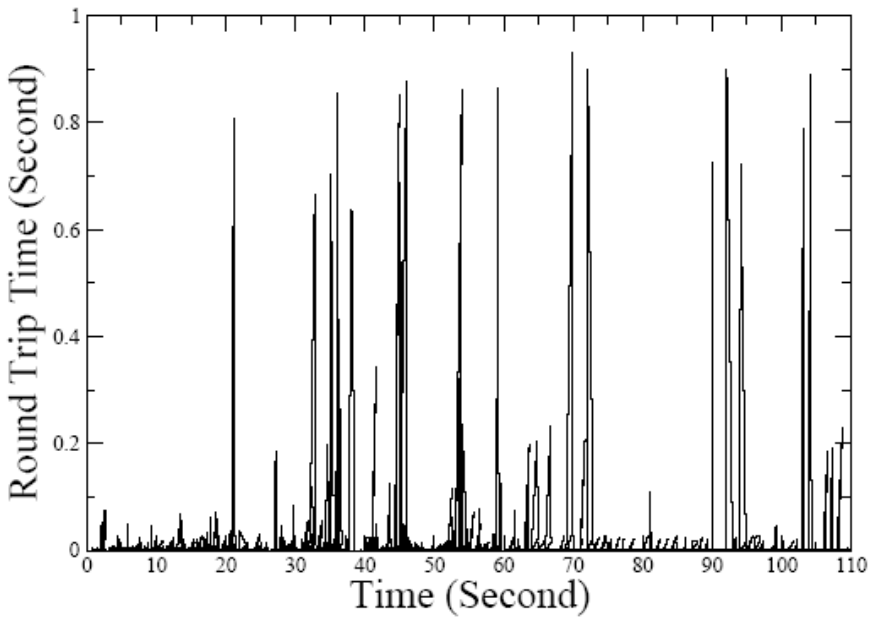

Figure 13. Throughput of video during SIGMA handoff

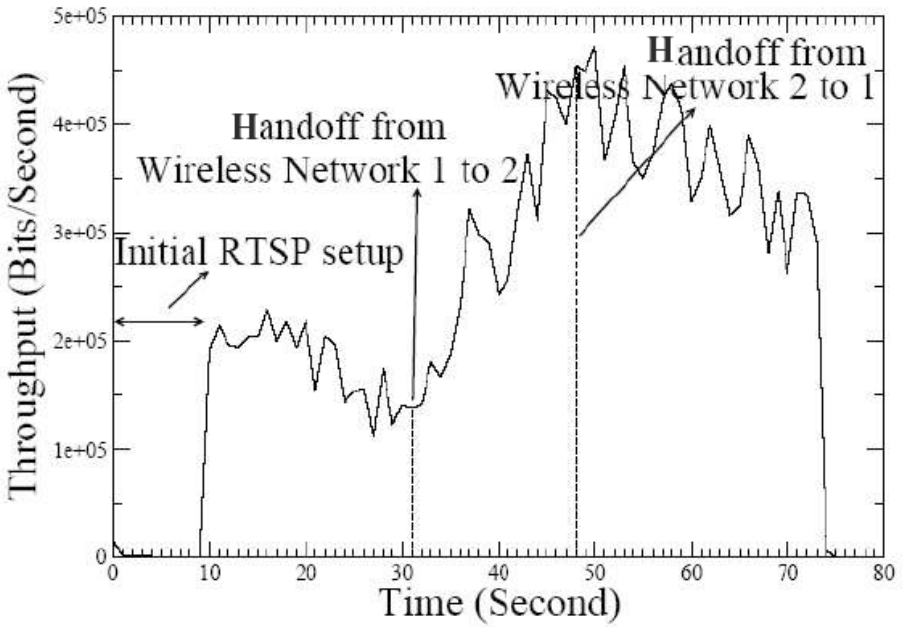

when MH moves from wireless network 1 to 2. A second handoff takes place when the MH moves from network 2 to network 1 at time = 48. It is seen that seamless handoff is achieved by SIGMA for both the handoffs.

Figure 14 shows a screen capture of the MPEG4IP player used in our experiment. Figure 15 shows the video playing in the player during handoff, where "rtsp://129.15.78.139/fta.sdp" represents the server's IP address and the streaming format (SDP).

Comparison of SIGMA and MIP Handoffs

We observed previously that the registration time of MIP was only 0.1 second, and the handoff latencies of MIP and SIGMA were eight seconds and six milliseconds, respectively. We describe the reasons for the MIP handoff latency being much longer than its registration time in the following:

1. In HUT Dynamics, the MIP implementation used in this study, the MH obtains a registration lifetime after every successful registration. It originates another registration on expiry of this lifetime. So it is possible for the MH to postpone registration even after it has completed a link layer handoff and received FA advertisements. This may introduce some delay which can be up to the duration of a life time.
2. As mentioned in the previous section, the registration of MH also costs some time, measured as 38.3 milliseconds in our testbed.

The handoff latency in MIP comes from three factors: (1) remaining home registration lifetime after link layer handoff which can be from zero to a lifetime, (2) FA advertisement interval plus the time span of last time advertisement which is not listened by MN, and (3) registration latency. During these three times, the CN cannot communicate through either the previous path because it

Figure 14. Screen shot of MPEG4-IP player

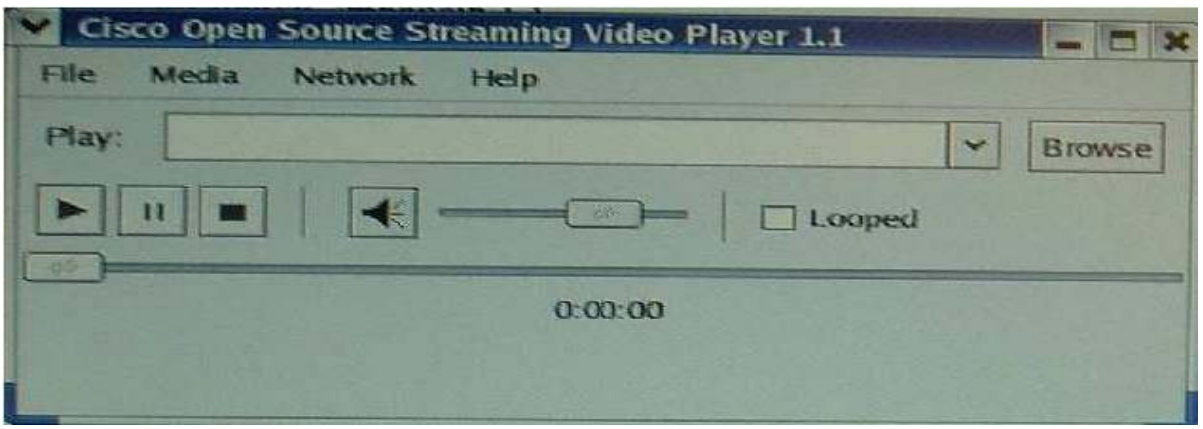

Figure 15. Screen-shot of MPEG4-IP player playing streaming video

has completed link layer handoff, or the new path because MH has not yet completed the registration. As a result, the throughput was zero during this time. Obviously, such shortcoming has been eliminated in SIGMA through multi-homing and decoupling of registration and data transfer. Consequently, data continue to flow between the CN and MH during the handoff process.

CONCLUSION AND FUTURE TRENDS

We have shown that SIGMA achieves seamless multimedia transmission during handoff between wireless networks. As future work, video streaming can be tested over SIGMA during vertical handoffs, that is, between wireless LANs, cellular, and satellite networks.

Monash University, Australia

ABSTRACT

Mobile multimedia, referring to multimedia information exchange over wireless networks or wireless Internet, is made possible due to the popularity and evolution of mobile computing devices, coupled with fast and affordable mobile networks. This chapter discusses various state-of-the-art communication technologies to support mobile multimedia. The range of complexity of applications and services provided to end-users also play an important part in the success of mobile multimedia.

INTRODUCTION

Number of subscribers for mobile communications has increased much faster than predicted, particularly for terrestrial use. In the year 2000, number of mobile subscribers was approximately 400 million worldwide, and in the year 2010 more than 1.8 billion mobile subscribers are estimated. An interesting fact was presented in a new report by Telecommunications Management Group, Inc. (TMG) (Wireless World Forum) providing the statistical basis to show the number of mobile multimedia users exceeding 100 million in 2004. This breathtaking fact inspires us to start

researching the mobile multimedia in all possible related aspects. In order to provide experts and researcher in the field of mobile multimedia, a description of basic definition of mobile multimedia is introduced, and then essential business driver controlling the mobile multimedia is illustrated. A full and up-to-date description of technologies beneath the mobile multimedia is presented. In addition to the services and applications, a set of mobile multimedia is discussed thoroughly, as well as anticipating the future of mobile multimedia.

The demand for mobile access to data no matter where the data is stored, what is kind of data and where the user happens to be, in addition to the explosive growth of the Internet and the rising popularity of mobile devices are among the factors that have created a dynamic business environment, where both handset manufacturers and service provider operators companies are competing to provide customers access to information resources and services anytime, anywhere.

Advances in wireless networking, specifically the development of the IEEE 802.11 and IEEE 802.16 protocol family and the rapid deployment and growth of GSM (and GPRS, 3G, 3GPP), have enabled a broad spectrum of novel and out breaking solutions for new applications and services. Voice services are no longer sufficient to satisfy customers' business and personal requirements. More and more people and companies are demanding for mobile access to multimedia services. Mobile multimedia seems to be the next mass market in mobile communications following the success of GSM and SMS. It enables the industry to create products and services to meet the consumer needs better. However, an innovation itself does not guarantee a success; it is necessary to be able to predict the new technology adaptation behavior and to try to fulfill customer needs rather than to wait for a demand pattern to surface.

The major step from the second generation to third generation and further to fourth generation was the ability to support advanced and wideband multimedia services, including emails, file transfers, and distribution services like radio, TV, and software provisioning (e.g., software download). These multimedia services can be symmetrical and asymmetrical services, real-time, and non real-time services.

It is beyond all expectations that mobile multimedia will create significantly added values for costumers by providing mobile access to Internet-based multimedia services, video conferencing, and streaming. Mobile multimedia is one of the mainstream systems for the next generation mobile communications, featuring large voice capacity, multimedia applications and high-speed mobile data services (Bull, Canagarajah, & Nix, 1999). As for the technology, the trend in the radio frequency area is to shift from narrowband to wideband with a family of standards tailored to a variety of application needs. Many enabling technologies including WCDMA, software-defined radio, intelligent antennas, and digital processing devices are greatly improving the spectral efficiency of third generation systems. In the mobile network area, the trend is to move from traditional circuit-switched systems to packet-switched programmable networks that integrate both voice and packet services, and eventually evolve towards an all-IP network (Bi, Zysman, & Menkes, 2001).

While for the information explosion, the addition of mobility to data communications systems has enabled a new generation of services not meaningful in a fixed network, such as positioning-based services. However, the development of mobile multimedia services has only started and in the future we will see new application areas opening up (Bi, Zysman, & Menkes, 2001; Blair, Coulson, Davies, Robin, & Fitzpatrick, 1997; Brown & Syfrig, 1996; Bruno, Conti, & Gregori, 2001; Bull, Canagarajah, & Nix, 1999).

Research in mobile multimedia is typically focused on bridging the gap between the high resource demands of multimedia applications and the limited bandwidth and capabilities offered

by state-of-the-art networking technologies and mobile devices.

Communication engineering approaches this problem by considering not only characteristics of the networks and devices used, but also on the tasks and objectives the user is pursuing when applying/demanding mobile multimedia services and exploit this information to better adapt those services to the users' needs. This method is referred to it as user centric multimedia processing approach.

Mobile Multimedia

External market studies have predicted that in Europe in the year 2010 more than 90 million mobile subscribers will use mobile multimedia services and will generate about 60% of the traffic in terms of transmitted bits. In China, the DGI predicted that there will be over 500 million mobile phones in China by year 2008, and over 150 million for multimedia applications. These results grab our attention how important it is to precisely define the mobile multimedia and its related terms.

Mobile multimedia can be defined as a set of protocols and standards for multimedia information exchange over wireless networks. It enables information systems to process and transmit multimedia data to provide end users with services from various areas, such as the mobile working place, mobile entertainment, mobile information retrieval, and context-based services.

Multimedia information as combined information presented by more than one media type (i.e. text, pictures, graphics, sounds, animations, videos) enriches the quality of the information and is a way to represent reality as adequately as possible. Multimedia allows users to enhance their understanding of the provided information and increases the potential of person to person and person to system communication.

Mobility as one of the key drivers of mobile multimedia can be decomposed into:

1. **User mobility:** The user is forced to move from one location to location during fulfilling his activities. For the user, the access to information and computing resources is necessary regardless his actual position (e.g., terminal services, VPNs to company-intern information systems).
2. **Device mobility:** User activities require a device to fulfill his needs regardless of the location in a mobile environment (e.g., PDAs, notebooks, tablet pc, cell-phones, etc.).
3. **Service mobility:** The service itself is mobile and can be used in different systems and can be moved seamlessly among those systems (e.g., mobile agents).

The special requirements coming along with the mobility of users, devices, and services; and specifically the requirements of multimedia as traffic type; bring the need of new paradigms in software-engineering and system-development; but also in non-technical issues such as the emergence of new business models and concerns about privacy, security, or digital inclusion, to name a few.

For instance, in the context of mobile multimedia, 3G communication protocols have great deals. Even some mobile protocol experts tend to define 3G as a mobile multimedia, personal services, the convergence of digitalization, mobility, and the internet, new technologies based on global standards, the entire of the aforementioned terms. In 3G, the end user will be able to access the mobile internet at the bandwidth at various bit rates. This makes great challenges for handset device manufacturers and mobile network operators. In addition, a large number of application and related issues need to be addressed considering the heterogeneity nature of the Internet. Also, the various and rich content of the internet should be considered whenever one of the roles of 3G is being deployed.

In network traffic point of view, the majority of traffic is changing from speech-oriented com-

munications to multimedia communications. It is also generally expected that due to the dominating role of mobile wireless access, the number of portable handsets will exceed the number of PCs connected to the Internet. Therefore, mobile terminals will be the major person-machine interface in the future instead of the PC. Due to the dominating role of IP-based data traffic in the future, the networks and systems have to be designed for economic packet data transfer. The expected new data services are highly bandwidth consuming. This results in higher data rate requirements for future systems.

Business Drivers

The key feature of mobile multimedia is reaching customers and partners, regardless of their locations and delivering multimedia content to the right place at the right time. Key drivers of this technology are on the one hand technical and on the other business drivers.

Evolutions in technology pushed the penetration of the mobile multimedia market and made services in this field feasible. The miniaturization of devices and the coverage of radio networks are the key technical drivers in the field of mobile multimedia.

1. **Miniaturization:** The first mobile phones had brick-like dimensions. Their limited battery capacity and transmission range restricted their usage in mobile environments. Actual mobile devices with multiple features fit into cases with minimal dimensions and can be (and are) carried by the user in every situation.
2. **Vehicle manufacturer:** Furthermore, mobility also calls for new types of services (and thus revenues). Vehicle manufacturers want to improve the ears' man-machine interface by using superior input/output devices. An open application platform would allow upgrading of multimedia equipment during the lifecycle of a vehicle, which is much longer than the lifetime of computing equipment. Safety equipment for automated emergency and breakdown calls brings positioning hardware into the car and thus enabling other location-aware services. But vehicle makers also seek an after-market relationship to their customers: Once having ears connected, they can offer ear-specific services, including direction-finding and safeguarding support.
3. **Radio networks:** Today's technology allows radio networks of every size for every application scenario. Nowadays public wireless wide-area networks cover the bulk of areas especially in congested areas. They enable (most of the time) adequate quality of service. They allow location-independent service provision and virtual private network access.
4. **Mobile terminal manufacturers:** Mobile terminal manufacturers serve individual people instead of households. Since there are more individuals than households, the market is naturally bigger then the home terminal market. Furthermore, there is a large potential for use and fashion-based diversification and innovation of terminals.
5. **Market evolution:** The market for mobile devices changed in the last years. Ten years ago the devices were not really mobile (short-time battery operation, heavy, and large devices) but therefore they have been expensive and affordable just for high-class business people. Shrinking devices and falling operation (network) costs made mobile devices to a mass-consumer-good available and affordable for everyone. The result is dramatic subscriber growth and therefore a new increasing market for mobile multimedia services.
6. **Subscribers:** Persons spend a good percentage of their lifetime traveling, either for business or leisure, while they want to

stay connected in every respect. This desire is more than proven by the current sales figures for mobile phones and the emerging standards for mobile narrow-band data services.

7. **Service evolution:** The permanent increasing market brought more and more sophisticated services, starting in the field of telecommunication from poor quality speech-communication to real-time video conferencing. Meanwhile, mobile multimedia services provide rich media content and intelligent context-based services.
8. **Vehicle terminal manufacturers:** Vehicle terminal manufacturers currently suffer from vertical markets due to high customization efforts for OEM products. An open application platform would help them to reduce development time and costs. It is also a key driver for after market products. A wide range of services will increase the number of terminals sold.
9. **Ears:** For ear drivers, security and travel assistance are important aspects as well. They probably want to use the same services in the car they are used to at home and in the office. This is only possible with an open application platform.

Technology drives mobile multimedia with new means to communicate, cache, process, and display multimedia content:

- **Connectivity:** New means to communicate enable new services to be provided.
- **Memory and persistent storage:** Developing memory technology allows caching of more content and offline processing, thus creating the illusion of instant access to interactive remote content. For example, audio/video content and whole Websites may be downloaded in background and consumed offline. This is above all important for data broadcast services, which are transmitted in different fashions.
- **Processing:** More processing resources with less power consumption allow rendering of more complex multimedia content.
- **Display:** Visualizing multimedia content demands for cheap high resolution displays that comply to "handset" requirements "screen driver, pixel per bits, width, height."

The value chain of mobile multimedia services describes the players involved in the business with mobile multimedia. Every service in the field of mobile multimedia requires that their output and service fees must be divided to them considering interdependencies in the complete service life-cycle.

1. **Network operators:** They provide end-users with the infrastructure to access services mobile via wireless networks (e.g., via GSM/GPRS/UMTS). The network operators want to boost the sales of network bandwidth, by enabling new types of services with new network technologies. In many countries a close cooperation between the transmitter and cellular network operators has been established to be able to offer hybrid network capacity. Service and content providers see the opportunity to promote and sell their services to people everywhere and anytime, thus increasing the total usage of their services.
2. **Content provider:** Content provider and aggregators license content and prepare it for end-users. They collect information and services to provide customers with convenient service collection adapted for mobile use. In another hand, some national broadcasters are forced by law to provide nationwide TV coverage through terrestrial transmission. They are interested in digital TV, because, firstly, it strongly reduces their transmission costs per channel by high ratio and, secondly, they improve the attractiveness of terrestrial reception which decreased strongly since the beginning of cable and satellite services

3. **Fixed Internet company:** Those companies create the multimedia content. Usually they provide it already via the fixed Internet but are not specialized on mobile service provisioning. They handle the computing infrastructure and content creation.
4. **App developers and device manufacturers:** They deliver hard- and software for mobile multimedia services and are not involved with any type of content creation and delivering.

COMMUNICATION TECHNOLOGIES

Wireless Wide Area Networks

After the first-generation analog mobile systems, the second-generation (2G) mobile digital systems were introduced around 1991 offering higher capacity and lower costs for network operators, while for the users, they offered short messages and low-rate data services added to speech services. Reader may refer to figure one as it holds general comparison among the first to four generation communication system. Presently, the 2G systems are GSM, TDMA, PDC, and cdmaOne. GSM is used in most parts of the world except in Japan, were PDC is the second-generation system used (Dixit, Guo, & Antoniou, 2001).

An important evolution of the 2G systems, sometimes known as 2.5G, is the ability to use packet-switched solution in GPRS (general packet radio system). The main investment for the operators lies in the new packet-switched core network, while the extensions in the radio access network mainly is software upgrades. For the users GPRS offers the possibility to always be online and only pay for the data actually transferred. Data rates of up to 20 kbps per used time slot will be offered, and with multiple time-slots per user in the downlink, attractive services can be offered (Stallings, 2001).

The shift to third-generation in the radio access networks is demanding a lot of efforts. The ITU efforts through IMT-2000 have led to a number of recommendations. These recommendations address areas such as user bandwidth, richness of service offerings (multimedia services), and flexibility (networks that can support small or large numbers of subscribers). The recommendations also specify that IMT-2000 should operate in the 2-GHz band. In general, however, the ITU recommendations are mainly a set of requirements and do not specify the detailed technical solutions to meet the requirements (UMTS Forum, 1998, 2000).

To address the technical solutions, the ITU has solicited technical proposals from interested organizations, and then selected/approved some of those proposals. In 1998, numerous air interface technical proposals were submitted. These were reviewed by the ITU, which in 1999 selected five technologies for terrestrial service (non-satellite based). The five technologies are (Collins & Smith, 2001):

- Wideband CDMA (WCDMA)
- CDMA 2000 (an evolution of IS-95 CDMA)
- TD-SCDMA (time division-synchronous CDMA)
- DECT
- UWC-136 (an evolution of IS-136)

Here is a brief description of each one of these selected technologies.

Wideband CDMA (WCDMA)

The worldwide introduction of WCDMA took place in 2001 and 2002, starting in Japan and continuing to Europe. In the U.S, several 3G alternatives will be available. GSM and TDMA operators can evolve toward EDGE, with WCDMA as a possible step, while cdmaOne operators can evolve toward cdma2000 systems.

WCDMA, as specified by the third-generation partnership project (3GPP), is a 3G system operat-

Figure 1. Comparison among the four generation communication system

1G	2G	3G	4G
Basic mobility	Advance mobility "roaming"	Seamless roaming	IP based mobility
Basic service	Various services "data exchange"	Service concept and model	Extremely high data rates
Incompatibility	Headed for global solution	Global solution	Perfect telecom, datacom convergence

ing in 5 MHz of bandwidth. Variable spreading and multicode operation is used to support a multitude of different radio access bearers. Different service classes are supported by an advanced quality-of-service (QoS) support. Data rates of up to 384 kbps for wide area coverage are provided (Bi, Zysman, & Menkes, 2001; Stallings, 2001; Dixit et al., 2001).

EDGE is an evolution of GPRS with data rates of up to 60 kbps per time-slot together with improved spectrum efficiency. EDGE uses higher-order modulation together with link adaptation and incremental redundancy to optimize the radio bearer to the radio connection characteristics. Currently, additions in the form of a new set of radio access bearers to align EDGE toward WCDMA are being standardized within the R5 of the 3GPP standards. The same service classes as in the WCDMA and the same interface to the core network will be used (Dornan, 2000; Ephremides et al., 2000; Fabri, Worrall, & Kondoz, 2000; Fasbender & Reichert, 1999; Flament et al., 1999; Frodigh, Parkvall, Roobol, Johansson, & Larsson, 2001).

CDMA 2000 (Evolution of IS-95 CDMA)

cdmaOne has evolved into cdma2000 and is available in two flavors, 1x and 3x. The former uses the same 1.25 Mhz bandwidth as cdmaOne and supports up to approximately 600 kbps, while the latter is a multi-carrier system using 3.75 Mhz and supporting approximately 2 Mbps at the moment, the focus on 3x is very limited. As a complement to 1x, the 3GPP2 has recently specified 1xEV-DO (1x Evolution-Data Only). 1xEV-DO uses a separate 1.25 Mhz carrier and supports best-effort data traffic only, using a new air interface compared to cdma2000 carrier. The peak rate in the 1x EV-DO downlink is almost 2.5 Mbps, excluding overhead. Phase two of the 1x evolution, known as 1xEV-DV (1x Evolution-Data and Voice), is currently being discussed within 3GPP2 and there are a number of proposals under consideration. The purpose is to specify an extension to cdma2000 1x in order to support high-rate data and voice on the same carrier (Bi, Zysman, & Menkes, 2001; Stallings, 2001; Dixit et al., 2001).

TD-SCDMA (Time Division-Synchronous CDMA)

UTRA TDD was developed to harmonize with the FDD component. This was achieved by harmonization of important parameters of the physical layer and a common set of protocols in the higher layers are specified for both FDD and TDD (Flament et al., 1999). TD-SCDMA has significant commonality with UTRA TDD. TD-SCDMA combines TDMA system with an adaptive CDMA component. TD-SCDMA eliminates the uplink/downlink interference, which affects other TDD methods by applying

"terminal synchronization" techniques, so TD-SCDMA can support of all radio network scenarios (Wide Area - Macro, Local Area - Micro, Hot Spots - Pico and Corporate Networks) to provide full service coverage. In this way, TD-SCDMA stands alongside W-CDMA and CDMA2000 as a fully-fledged 3G standard (Wireless Ethernet Compatibility Alliance).

DECT

DECT (digital enhanced cordless telecommunications) (European Telecommunications Standards) is a common standard for cordless personal telephony established by ETSI. DECT is used for those cordless communication systems which supports only indoor and pedestrian environment, but it does not allow full network coverage so is not satisfied to all requirements of third generation system.

UWC-136 (Evolution of IS-136)

DECT is based on TDMA. Different from UWC-136 (also based on TDMA), which uses two separate bandwidths (200 kHz provides medium bit rates up to 384 Kb/s and 1.6 MHz provides highest bit rates up to 2 Mb/s), DECT uses only one carrier with 1.728 MHz bandwidth. Variable bit rates are achieved by allocating different numbers of basic channels to a user. TDMA is flexible for TDD with asymmetric services and the training sequence is optimized for high bit rate services (Veerakachen, Pongsanguansin, & Sanguanpong, 1999).

In the fourth generation mobile communication (4G mobile), the combination and convergence of the different world's information technology industry, media industry and telecommunications will incorporate communication with information technology. As a result, mobile communications together with information technology will penetrate into the various fields of the society. In the future, 4G mobile (global and ubiquitous) communications will make people free from spatial and temporal constraints. Versatile communication systems will also be required to realize customized services based on diverse individual needs. The user outlook are increasing with regard to a large variety of services and applications with diverse degree of quality of service (QoS), which is related to delay, data rate, and bit error requirements. Therefore, seamless services and applications via different access systems and technologies that take full advantage of the use of available spectrum will be the driving forces for future developments.

Wireless Local Area Networks

Wireless local area networks (WLANs) based on the different versions of IEEE 802.11 standard have been around for some years in the 2.4 GHz ISM licensed band. Data rates up to 11 Mbps (802.11b) with reasonable indoor coverage have been offered, another licensed band is the microwave ovens which operates on 2.45 GH.

The ISM band is used in:

- 802.11
- Bluetooth
- Spread spectrum cordless phone

In an attempt to attain higher data rates new standards were proposed to operate on 5 GHz band with a rate up to 54 Mbps. Products based on two different standards, HIPERLAN 2 (H2) and IEEE 802.11a, The physical layers of the two are more or less identical with some differences where hiperlan2 uses several types of preambles but only PLCP is used in 802.11a to maintain synchronization and in modulation schemes (hiperlan2 supports 7 modes while 80.11a supports 8), with a carrier spacing of 20 MHz, OFDM modulation, and data rates up to 54 Mbps. The difference is the MAC protocol, where Hiperlan 2 has a more advanced protocol supporting QoS and mobility in a consistent way (Bi, Zysman, & Menkes, 2001).

802.11g is proposed to support high rates too up to 54 Mbps, Networks employing 802.11g operate at radio frequencies between 2.400 GHz and 2.4835 GHz, the same band as 802.11b (11 Mbps). But the 802.11g specification employs orthogonal frequency division multiplexing (OFDM), the modulation scheme used in 802.11a, to obtain higher data speed.

IEEE 802.11x

The current IEEE 802.11 (IEEE, 1999) is known to lack a viable security mechanism. In order to address this issue, IEEE has proposed the robust security network (RSN). RSN approved the 802.1x standard to provide strong authentication, access control, and key management. In a wireless environment, there are no physical perimeters, thus, the network access authentication must be provided. In this case, RSN provides mechanisms to restrict network connectivity to authorized entities only via 802.1x.

802.1x also provides various authentication methods such as one-time password and smartcards. It provides network access control for hybrid networking technologies (e.g., not only for wireless).

There are three entities specified in the IEEE 802.1x standard, including: supplicant, authenticator, and authentication server.

Wi-Fi

Wi-Fi (short for "wireless fidelity") is a term for certain types of wireless local area network (WLAN) that uses specifications in the 802.11 family (Vaughan-Nichols, 2003). The term Wi-Fi was created by an organization called the Wi-Fi Alliance, which oversees tests that certify product interoperability. A product that passes the alliance tests is given the label "Wi-Fi certified" (a registered trademark).

Originally, Wi-Fi certification was applicable only to products using the 802.11b standard (Ferro & Potorti, 2005). Today, Wi-Fi can apply to products that use any 802.11 standard. The 802.11 specifications are part of an evolving set of wireless network standards known as the 802.11 family. The particular specification under which a Wi-Fi network operates is called the "flavor" of the network. Wi-Fi has gained acceptance in many businesses, agencies, schools, and homes as an alternative to a wired LAN. Many airports, hotels, and fast-food facilities offer public access to Wi-Fi networks. These locations are known as hot spots. Many charge a daily or hourly rate for access, but some are free. An interconnected area of hot spots and network access points is known as a hot zone.

Unless adequately protected (Hole, Dyrnes, & Thorsheim, 2005), a Wi-Fi network can be susceptible to access by unauthorized users who use the access as a free Internet connection. The activity of locating and exploiting security-exposed wireless LANs is called war driving. An identifying iconography, called war chalking, has evolved. Any entity that has a wireless LAN should use security safeguards such as the wired equivalent privacy (WEP) encryption standard, the more recent Wi-Fi protected access (WPA), Internet protocol security (IPsec), or a virtual private network (VPN).

HiperLAN

It is a WLAN communication standard primarily used in European countries. There are two specifications: HiperLAN/1 and HiperLAN/2. Both have been adopted by the European Telecommunications Standards Institute (ETSI). The HiperLAN standards provide features and capabilities similar to 802.11. HiperLAN/1 provides communications at up to 20 Mbps in the 5-GHz range of the radio frequency (RF) spectrum. HiperLAN/ 2 is defined as a flexible Radio LAN standard designed to provide high speed access up to 54 Mbps to a variety of networks including 3G mobile core networks, ATM networks, and

IP-based networks, and also for private use as a wireless LAN system. Basic applications include data, voice and video, with specific Quality of Service (QoS) parameters taken into account. HiperLAN/2 systems can be deployed in offices, classrooms, homes, factories, hot spot areas like exhibition halls, and more generally where radio transmission is an efficient alternative or a complement to wired technology. It is worth noting that HiperLAN/2 has been developed in conjunction with the Japanese standards body, the Association of Radio Industries and Broadcasting.

HiperLAN/2 offers a number of advantages over 802.11a in that it incorporates quality of service (QoS) features. However, there is a long tradition of Europe developing standards which are not adopted because the US does something different. Most observers suggest that HiperLAN/2 will loose out to 802.11a, but that some of the features developed by ETSI will be incorporated in revised versions of the 802.11a standard.

WiMAX

WiMAX (Ghosh et al., 2005; Vaughan-Nichols, 2004; Hamalainen et al., 2002; Giuliano & Mazzenga, 2005) is a wireless industry coalition whose members organized to advance IEEE 802.16 standards for broadband wireless access (BWA) networks. WiMAX 802.16 technology is expected to enable multimedia applications with wireless connection and, with a range of up to 30 miles, enable networks to have a wireless last mile solution.

WiMAX was formed in April 2001, in preparation for the original 802.16 specification published in December of that year. According to the WiMAX forum, the group's aim is to promote and certify compatibility and interoperability of devices based on the 802.16 specification, and to develop such devices for the marketplace. Members of the organization include Airspan, Alvarion, Analog Devices, Aperto Networks, Ensemble Communications, Fujitsu, Intel, Nokia, OFDM Forum, Proxim, and Wi-LAN

WiMAX is a wireless industry coalition whose members organized to advance IEEE 802.16 standards for broadband wireless access (BWA) networks. WiMAX 802.16 technology is expected to enable multimedia applications with wireless connection and, with a range of up to 30 miles, enable networks to have a wireless last mile solution (Giuliano & Mazzenga, 2005; Ghavami, Michael, & Kohno, 2005). For reader reference, we are attaching a general specifications Table 1 for WiMAX standard.

Wireless Personal Area Networks

A WPAN (wireless personal area network) is a personal area network—a network for interconnecting devices centered around an individual person's work space—in which the connections are wireless. Typically, a wireless personal area network uses some technology that permits communication within about 10 meters—in other words, a very short range. One such technology is Bluetooth, which was used as the basis for a new standard, IEEE 802.15.

Table 1. WiMax (IEEE 802.16) specifications

Frequency range	Modulation	Multiple access	Duplex	Channel bandwidth	Number of channels	Peak data rate
2 GHz to 66GHz in various bands	BPSK, QPSK, 16QAM, 64QAM, QFDM, SC	TDMA/ OFDMA	TDD/ FDD	In accordance with local radio regulations	79	15 Mbit/s (5MHz channel) to 134 Mbit/s (28 MHz channel)

A WPAN could serve to interconnect all the ordinary computing and communicating devices that many people have on their desk or carry with them today—or it could serve a more specialized purpose such as allowing the surgeon and other team members to communicate during an operation.

A key concept in WPAN technology is known as plugging in. In the ideal scenario, when any two WPAN-equipped devices come into close proximity (within several meters of each other) or within a few kilometers of a central server, they can communicate as if connected by a cable. Another important feature is the ability of each device to lock out other devices selectively, preventing needless interference or unauthorized access to information.

The technology for WPANs is in its infancy and is undergoing rapid development. Proposed operating frequencies are around 2.4 GHz in digital modes. The objective is to facilitate seamless operation among home or business devices and systems. Every device in a WPAN will be able to plug in to any other device in the same WPAN, provided they are within physical range of one another. In addition, WPANs worldwide will be interconnected. Thus, for example, an archeologist on site in Greece might use a PDA to directly access databases at the University of Minnesota in Minneapolis, and to transmit findings to that database.

Infrared IR

802.11 also includes a specification for a physical layer based on infrared (IR) that is low enough that IR ports are standard on practically every laptop. IR is extremely tolerant of radio frequency (RF) interference because radio IR is unregulated. Product developers do not need to investigate and comply with directives from several regulatory organizations throughout the world and unauthorized users connecting to a network. Light can be confined to concerns. This comes at a price. IR LANs rely on scattering light off the ceiling, so range is much shorter. This discussion is academic, however.
